∗UNC Chapel Hill †IBM Research ‡UConn §CWI Amsterdam

Abstract

We propose a novel hybrid stochastic policy gradient estimator by combining an unbiased policy gradient estimator, the REINFORCE estimator, with another biased one, an adapted SARAH estimator for policy optimization. The hybrid policy gradient estimator is shown to be biased, but has variance reduced property. Using this estimator, we develop a new Proximal Hybrid Stochastic Policy Gradient Algorithm (ProxHSPGA) to solve a composite policy optimization problem that allows us to handle constraints or regularizers on the policy parameters. We first propose a single-looped algorithm then introduce a more practical restarting variant. We prove that both algorithms can achieve the best-known trajectory complexity $O(\varepsilon^{-3})$ to attain a first-order stationary point for the composite problem which is better than existing REINFORCE/GPOMDP $O(\varepsilon^{-4})$ and SVRPG $O(\varepsilon^{-10/3})$ in the non-composite setting. We evaluate the performance of our algorithm on several well-known examples in reinforcement learning. Numerical results show that our algorithm outperforms two existing methods on these examples. Moreover, the composite settings indeed have some advantages compared to the non-composite ones on certain problems.

1 Introduction

Recently, research on reinforcement learning (RL) (Sutton and Barto 2018), an area of machine learning...
chronous variant A2C, ACKTR (Wu et al., 2017), and SAC (Haarnoja et al., 2018).

REINFORCE (Williams, 1992) is perhaps one classical method closely related to our work here. It uses an estimator of the policy gradient and applies a gradient ascent step to update the policy. Nevertheless, the REINFORCE estimator is known to have high variance leading to several weaknesses. Other improvements to reduce the variance such as adding baselines (Sutton and Barto, 2018; Zhao et al., 2011), discarding some rewards in the so-called GPOMDP estimator (Baxter and Bartlett, 2001) were proposed. While REINFORCE estimator is an unbiased policy gradient estimator, GPOMDP is shown to be biased (Baxter and Bartlett, 2001) making theoretical analysis harder.

The nature of REINFORCE algorithm appears to be closely related to stochastic gradient descent (SGD) (Robbins and Monro, 1951) in stochastic nonconvex optimization. In particular, the standard SGD estimator is also known to often have fixed variance, which is often high. On the one hand, there are algorithms trying to reduce the oscillation (Tieleman and Hinton, 2012) or introduce momentum or adaptive updates (Allen-Zhu, 2017, 2018; Kingma and Ba, 2014) for SGD methods to accelerate performance. On the other hand, other researchers are searching for new gradient estimators. One approach is the SAGA estimator proposed by Defazio et al. (2014). Another well-known estimator is the SVRG estimator (Johnson and Zhang, 2013), which has been intensively studied in recent works, e.g., in (Allen-Zhu and Yuan, 2016; Reddi et al., 2016; Zhou et al., 2018). This estimator not only overcomes the storage issue of SAGA but also possesses variance reduced property, i.e., the variance of the estimator decreases over epochs. Methods based on SVRG estimators have recently been developed for reinforcement learning, e.g., SVRPG (Papini et al., 2018), VRMPO (Yang and Zhang, 2019) and HAPG (Shen et al., 2019). Mean-while, we introduce a new policy gradient estimator which can also be calculated recursively. The new estimator is fundamentally different from the other two since it combines the adapted SARAH estimator as in Xu et al. (2019b) with the classical REINFORCE estimator. In addition, our analysis shows that the best-known convergence rate and complexity can be achieved by our single-loop algorithm (Algorithm 1) while SRVR-PG and VRMPO require double loops to achieve the same oracle complexity. Moreover, Xu et al. (2019b), Yang and Zhang (2019) do not consider the composite setting that includes the constraints or regularizers on the policy parameters as we do.

Table 1: A comparison between different methods for the non-composite setting (1) of (2).

| Algorithms          | Complexity | Composite | Single-loop |
|---------------------|------------|-----------|-------------|
| REINFORCE (Williams, 1992) | $O(\varepsilon^{-3})$ | $\times$ | $\checkmark$ |
| GPOMDP (Baxter and Bartlett, 2001) | $O(\varepsilon^{-3})$ | $\times$ | $\checkmark$ |
| SVRPG (Papini et al., 2018) | $O(\varepsilon^{-3})$ | $\times$ | $\times$ |
| VRMPO (Yang and Zhang, 2019) | $O(\varepsilon^{-3})$ | $\times$ | $\times$ |
| HAPG (Shen et al., 2019) | $O(\varepsilon^{-3})$ | $\times$ | $\times$ |

| This work          | $O(\varepsilon^{-3})$ | $\checkmark$ | $\checkmark$ |

Our approach: Our approach lies in the stochastic variance reduction avenue, but using a completely new hybrid approach, leading to a novel estimator compared to existing methods in reinforcement learning. We build our estimator by taking a convex combination of the adapted SARAH (Nguyen et al., 2017b) and REINFORCE (Williams, 1992), a classical unbiased policy gradient estimator. This hybrid estimator not only allows us to trade-off the bias and variance between these two estimators but also possesses...
useful properties for developing new algorithms. Note that the idea of combining stochastic estimators was first proposed for stochastic optimization in our recent works [Tran-Dinh et al., 2019a,b]. Unlike existing policy gradient methods, our algorithm first samples a large batch of trajectories to establish a good search direction. After that, it iteratively updates the policy parameters using our hybrid estimator leading to a single-loop method without any snapshot loop as in SVRG or SARAH variants. In addition, as regularisation techniques have shown their effectiveness in deep learning [Neyshabur et al., 2017; Zhang et al., 2017], they possibly have great potential in reinforcement learning algorithms too. A recent study [Liu et al., 2019] shows that regularizations on the policy parameters can greatly improve the performance of policy gradient algorithms. Motivated by these facts, we directly consider a new composite setting as presented in Section 2. For this new composite model, it is not clear if existing algorithms remain convergent by simply adding a projection step on the constraint set, while our method does guarantee convergence.

Our contribution: To this end, our contribution in this paper can be summarized as follows:

(a) We introduce a novel hybrid stochastic policy gradient estimator by combining existing REINFORCE estimator with the adapted SARAH estimator for policy gradient. We investigate some key properties of our estimator that can be used for algorithmic development.

(b) We propose a new algorithm to solve a composite maximization problem for policy optimization in reinforcement learning. Our model not only covers existing settings but also handles constraints and convex regularizers on policy parameters.

(c) We provide convergence analysis as the first theoretical result for composite optimization in reinforcement learning and estimate the trajectory complexity of our algorithm and show that our algorithm can achieve the best-known complexity over existing first-order methods (see Table 1).

Our algorithm only has one loop as REINFORCE or GPOMDP, which is fundamentally different from SVRG, SVRG-adapted, and other SARAH-based algorithms for RL. It can work with single sample or mini-batch and has two steps: proximal gradient step and averaging step with different step-sizes. This makes the algorithm more flexible to use different step-sizes without sacrificing the overall complexity.

Paper outline: The rest of this paper is organized as follows. Section 2 describes problem of interest and gives an overview about policy gradient methods. Section 3 introduces our new hybrid estimator for policy gradient and develops the main algorithm. The complexity analysis is presented in Section 4 while Section 5 provides several numerical examples. All technical proofs and experimental details are given in Supplementary Document (Supp. Doc.).

2 Model and Problem Statement

Model: We consider a Markov Decision Process (MDP) [Sutton and Barto, 2018] equipped with 6 components \(\{S, A, P, R, \gamma, P_0\}\) where \(S, A\) are the state and action spaces, \(P\) denotes the set of transition probabilities when taking certain actions, \(R\) is the reward function which characterizes the immediate reward earned by taking certain action, \(\gamma\) is a discount factor, and \(P_0\) is the initial state distribution.

Let \(\pi(\cdot|s)\) be a density function over \(A\) when current state is \(s\) and \(\pi_\theta(\cdot|s)\) is a policy parameterized by parameter \(\theta\). A trajectory \(\tau = \{s_0, a_0, s_1, a_1, \cdots, s_{H-1}, a_{H-1}\}\) with effective length \(H\) is a collection of states and actions sampled from a stationary policy. Denote \(p_\theta(\cdot)\) as the density induced by policy \(\pi_\theta\) over all possible trajectories and \(p_\theta(\tau)\) is the probability of observing a trajectory \(\tau\). Also, let \(R(\tau) = \sum_{j=0}^{H-1} \gamma^j R(s_t, a_t)\) be the total discounted reward for a trajectory \(\tau\). Solving an MDP is equivalent to finding the solution that maximizes the expected cumulative discounted rewards.

Classical policy gradient methods: Policy gradient methods seek a differentiable parameterized policy \(\pi_\theta\) that maximizes the expected cumulative discounted rewards as

\[
\max_{\theta \in \mathbb{R}^q} \left\{ J(\theta) := \mathbb{E}_{\tau \sim p_\theta} [R(\tau)] \right\},
\]

where \(q\) is the parameter dimension. The policy gradient theorem [Sutton et al., 1999] shows that

\[
\nabla J(\theta) = \mathbb{E}_{\tau \sim p_\theta} \left[ \nabla \log p_\theta(\tau) R(\tau) \right],
\]

where the policy gradient does not depend on the gradient of the state distribution despite the fact that the state distribution depends on the policy parameters [Silver et al., 2014].

This policy gradient can be used in gradient ascent algorithms to update the parameter \(\theta\). However, we cannot calculate the full gradient at each update as we only get a finite number of samples at each iteration. Consequently, the policy gradient is often estimated by its sample average. At each iteration, a batch of trajectories \(B = \{\tau_i\}_{i=1,\cdots,N}\) will be sampled from the environment to estimate the policy gradient as

\[
\nabla J(\theta) := \frac{1}{N} \sum_{i=1}^{N} g(\tau_i|\theta),
\]
where $g(\tau|\theta)$ is a sample estimator of $E_{\tau \sim p_\theta} [\nabla \log p_\theta(\tau) R(\tau)]$. We call $\nabla J(\theta)$ a stochastic policy gradient (SPG) estimator. This estimator has been exploited in the two well-known REINFORCE (Williams, 1992) and GPOMDP (Baxter and Bartlett, 2001) methods. The main step of policy gradient ascent methods is to update the parameters as 
$$
\theta_{t+1} := \theta_t + \eta \nabla J(\theta_t), \ t = 0, 1, \cdots ,
$$
where $\eta > 0$ is some appropriate learning rate, which can be fixed or varied over $t$. Since the policy changes after each update, the density $p_\theta(\cdot)$ also changes and creates non-stationarity in the problem which will be handled by importance weight in Section 3.

3 A New Hybrid Stochastic Policy Gradient Algorithm

In this section, we first introduce a composite model for policy optimization. Next, we extend the hybrid gradient idea from [Tran-Dinh et al., 2019b] to policy gradient estimators. Finally, we develop a new proximal policy gradient algorithm and its restart variant to solve the composite policy optimization problem and analyze their trajectory complexity.

3.1 Composite Policy Optimization Model

While the objective function in (1) is standard in most policy gradient methods, it is natural to have some constraints or regularizers on the policy parameters. In addition, adding constraints can prevent the explosion of parameters in highly nonlinear models as often seen in deep learning (Srivastava et al., 2014). Adopting the idea of composite nonconvex optimization (Pham et al., 2019b), we are interested in the more general optimization problem in reinforcement learning as follow:

$$
\max_{\theta \in \mathbb{R}^q} \left\{ J(\theta) - Q(\theta) = E_{\tau \sim p_\theta} [R(\tau)] - Q(\theta) \right\},
$$

where $Q(\theta)$ is a proper, closed, and convex function acting as a regularizer which can be the indicator function of a convex set representing the constraints on the parameters or some standard regularizers such as $l_1$-norm or $l_2$-norm. If there is no regularizer $Q(\theta)$, the problem (2) reduces to the standard one in (1).

3.2 Assumptions

Let $F(\theta) := J(\theta) - Q(\theta)$ be the total objective function. We impose the following assumptions for our convergence analysis, which are often used in practice.

Assumption 3.1. The regularizer $Q : \mathbb{R}^q \to \mathbb{R} \cup \{+\infty\}$ is a proper, closed, and convex function. We also assume that the domain of $F$ is nonempty and there exists a finite upper bound

$$
F^* := \sup_{\theta \in \mathbb{R}^q} \{ F(\theta) := J(\theta) - Q(\theta) \} < +\infty.
$$

Assumption 3.2. The immediate reward function is bounded, i.e., there exists $R > 0$ such that for all $a \in A, s \in S$, $|R(s, a)| \leq R$.

Assumption 3.3. Let $\pi_\theta(s, a)$ be the policy for a given state-action pair $(s, a)$. Then, there exist two positive constants $G$ and $M$ such that

$$
\| \nabla \log \pi_\theta(s, a) \| \leq G \text{ and } \| \nabla^2 \log \pi_\theta(s, a) \| \leq M,
$$

for any $a \in A, s \in S$ where $\| \cdot \|$ is the $l_2$-norm.

This assumption leads to useful results about the smoothness of $J(\theta)$ and $g(\tau|\theta)$ and the upper bound on the variance of the policy gradient estimator.

Lemma 3.1 ([Papini et al., 2018; Shen et al., 2019; Xu et al., 2019a]). Under Assumption 3.2 and 3.3, for all $\theta, \theta_1, \theta_2 \in \mathbb{R}^q$, we have

- $\| \nabla J(\theta_1) - \nabla J(\theta_2) \| \leq L \| \theta_1 - \theta_2 \|$;
- $\| g(\tau|\theta_1) - g(\tau|\theta_2) \| \leq L_g \| \theta_1 - \theta_2 \|$;
- $\| g(\tau, \theta) \| \leq C_g$; and
- $\| g(\tau|\theta) - \nabla J(\theta)^2 \| \leq \sigma^2$,

where $g(\cdot)$ is the REINFORCE estimator and $L, L_g, C_g$ and $\sigma^2$ are constants depending only on $R, G, M, H, \gamma$, and the baseline $b$.

For more details about the constants and the proofs of Lemma 3.1 we refer e.g., to [Papini et al., 2018; Shen et al., 2019; Xu et al., 2019a].

Assumption 3.4. There exists a constant $W \in (0, \infty)$ such that, for each pair of policies encountered in Algorithm 1, the following holds

$$
\text{Var} [\omega(\tau|\theta_1, \theta_2)] \leq W; \ \theta_1, \theta_2 \in \mathbb{R}^q, \ \tau \sim p_\theta(\cdot),
$$

where $\omega(\tau|\theta_1, \theta_2) = \frac{p_{\theta_1}(\tau)}{p_{\theta_2}(\tau)}$ is the importance weight between $p_{\theta_1}(\cdot)$ and $p_{\theta_2}(\cdot)$.

Since the importance weight $\omega$ introduces another source of variance, we require this assumption for our convergence analysis as used in previous works, e.g., in [Papini et al., 2018; Xu et al., 2019a].

Remark 3.1. [Cortes et al., 2010] shows that if $\sigma_Q, \sigma_P$ are variances of two Gaussian distributions $P$ and $Q$, and $\sigma_Q > \frac{1}{\sqrt{2}} \sigma_P$ then the variance of the importance weights is bounded, i.e., Assumption 3.4 holds for Gaussian policies which are commonly used to represent the policy in continuous control tasks.
3.3 Optimality Condition

Associated with problem (2), we define
\[ G_\eta(\theta) := \eta^{-1} \left[ \text{prox}_{\eta Q}(\theta + \eta \nabla J(\theta)) - \theta \right], \tag{3} \]
for some \( \eta > 0 \) as the gradient mapping of \( F(\theta) \) (Nesterov, 2014), where \( \text{prox}_{\eta Q}(\theta) := \arg\min_{\theta'} \{ Q(\theta') + \frac{1}{2\eta} \| \theta' - \theta \|^2 \} \) denotes the proximal operator of \( Q \) (see, e.g., Parikh and Boyd (2014) for more details).

A point \( \theta^* \) is called a stationary point of (2) if
\[ E \left[ \| G_\eta(\theta^*) \|^2 \right] = 0. \]

Our goal is to design an iterative method to produce an \( \varepsilon \)-approximate stationary point \( \theta_T \) of (2) after at most \( T \) iterations defined as
\[ E \left[ \| G_\eta(\theta_T) \|^2 \right] \leq \varepsilon^2, \]
where \( \varepsilon > 0 \) is a desired tolerance, and the expectation is taken overall the randomness up to \( T \) iterations.

3.4 Novel Hybrid SPG Estimator

Unbiased estimator: Recall that given a trajectory \( \tau := \{ s_0, a_0, \cdots, s_{H-1}, a_{H-1} \} \), the REINFORCE (SPG) estimator is defined as
\[ g(\tau|\theta) := \left[ \sum_{t=0}^{H-1} \nabla \log \pi_\theta(a_t|s_t) \right] \mathcal{R}(\tau), \]
where \( \mathcal{R}(\tau) := \sum_{t=0}^{H-1} \gamma^t \mathcal{R}(s_t, a_t) \).

Note that the REINFORCE estimator is unbiased, i.e. \( E_{\tau \sim p_\theta} [g(\tau|\theta)] = \nabla J(\theta) \). In order to reduce the variance of these estimators, a baseline is normally added while maintaining the unbiasedness of the estimators (Sutton and Barto, 2018; Zhao et al., 2011). From now on, we will refer to \( g(\tau|\theta) \) as the baseline-added version defined as
\[ g(\tau|\theta) := \sum_{t=0}^{T-1} \nabla \log \pi_\theta(a_t|s_t) A_t, \]
where \( A_t := \mathcal{R}(\tau) - b_t \) with \( b_t \) being a baseline and possibly depending only on \( s_t \).

Hybrid SPG estimator: In order to reduce the number of trajectories sampled, we extend our idea in (Tran-Dinh et al., 2019b) for stochastic optimization to develop a new hybrid stochastic policy gradient (HSPG) estimator that helps balance the bias-variance trade-off. The estimator is formed by taking a convex combination of two other estimators: one is an unbiased estimator which can be REINFORCE estimator, and another is the adapted SARAH estimator (Nguyen et al., 2017b) for policy gradient which is biased.

More precisely, if \( B_t \) and \( \hat{B}_t \) are two random batches of trajectories with sizes \( B \) and \( \hat{B} \), respectively, sampled from \( p_{\theta_t}(\cdot) \), the hybrid stochastic policy gradient estimator at \( t \)-th iteration can be expressed as
\[ v_t := \beta v_{t-1} + \frac{\bar{E}}{B} \sum_{\tau \in B} \Delta g(\tau|\theta_t) + \frac{(1-\beta)}{B} \sum_{\tau \in \hat{B}} g(\tau|\theta_t), \tag{4} \]
where \( \Delta g(\tau|\theta_t) := g(\tau|\theta_t) - \omega(\tau|\theta_t, \theta_{t-1}) g(\tau|\theta_{t-1}) \), and
\[ v_0 := \frac{1}{N} \sum_{\tau \in B} g(\tau|\theta_0), \]
with \( \hat{B} \) is a batch of trajectories collected at the beginning. Note that \( \omega(\tau|\theta_t, \theta_{t-1}) \) is an importance weight added to account for the distribution shift since the trajectories \( \tau \in B_t \) are sampled from \( p_{\theta_t}(\cdot) \) but not from \( p_{\theta_{t-1}}(\cdot) \). Note also that \( v_t \) in (4) is also different from the momentum SARAH estimator recently proposed in Cutkosky and Orabona (2019).

3.5 The Complete Algorithm

The novel Proximal Hybrid Stochastic Policy Gradient Algorithm (abbreviated by ProxHSPGA) to solve (2) is presented in detail in Algorithm 1.

Algorithm 1 (ProxHSPGA)
1: Initialization: An initial point \( \theta_0 \in \mathbb{R}^\tau \), and positive parameters \( m, N, B, \hat{B}, \beta, \alpha, \eta \) and \( \eta \) (specified later).
2: Sample a batch of trajectories \( \hat{B} \) of size \( N \) from \( p_{\theta_0}(\cdot) \).
3: Calculate \( v_0 := \frac{1}{N} \sum_{\tau \in B} g(\tau|\theta_0) \).
4: Update
\[ \theta_1 := (1 - \alpha) \theta_0 + \alpha \hat{\theta}_1, \]
5: For \( t := 1, \cdots, m \) do
6: Generate 2 independent batches of trajectories \( B_t \) and \( \hat{B}_t \), with size \( B \) and \( \hat{B} \) from \( p_{\theta_t}(\cdot) \).
7: Evaluate the hybrid estimator \( v_t \) as in (4).
8: Update
\[ \hat{\theta}_{t+1} := \text{prox}_{\eta \mathcal{Q}}(\hat{\theta}_t + \eta v_t), \]
\[ \hat{\theta}_{t+1} := (1 - \alpha) \hat{\theta}_t + \alpha \hat{\theta}_{t+1}. \]
9: EndFor
10: Choose \( \theta_T \) from \( \{ \theta_t \}_{t=1}^m \) uniformly randomly.

Unlike SVRPG (Papini et al., 2018; Xu et al., 2019a) and HAPG (Shen et al., 2019), Algorithm 1 only has one loop as REINFORCE or GPOMDP. Moreover, Algorithm 1 does not use the estimator for the policy Hessian as in HAPG. At the initial stage, a batch of
trajectories is sampled using $p_{\theta_0}$ to estimate an initial policy gradient estimator which provides a good initial search direction. At the $t$-th iteration, two independent batches of trajectories are sampled from $p_{\theta_t}$ to evaluate the hybrid stochastic policy gradient estimator. After that, a proximal step followed by an averaging step are performed which are inspired by Pham et al. (2019b). Note that the batches of trajectories at each iteration are sampled from the current distribution which will change after each update. Therefore, the importance weight $\omega(\tau|\theta_t, \theta_{t-1})$ is introduced to account for the non-stationarity of the sampling distribution. As a result, we still have $E_{\tau \sim p_{\theta_t}} [\omega(\tau|\theta_t, \theta_{t-1})g(\tau|\theta_{t-1})] = \nabla J(\theta_{t-1})$.

### 3.6 Restarting variant

While Algorithm 1 has the best-known theoretical complexity as shown in Section 3, its practical performance may be affected by the constant step-size $\alpha$ depending on $m$. As will be shown later, the step-size $\alpha \in [0, 1]$ is inversely proportional to the number of iterations $m$ and it is natural to have $\alpha$ close to 1 to take advantage of the newly computed information. To increase the practical performance of our algorithm without sacrificing its complexity, we propose to inject a simple restarting strategy by repeatedly running Algorithm 1 for multiple stages as in Algorithm 2.

**Algorithm 2** (Restarting ProxHSPGA)

1: **Initialization**: Input an initial point $\theta_0^{(0)}$.
2: **For** $s := 0, \cdots, S-1$ **do**
3: 
   3.1 Run Algorithm 1 with $\theta_0 := \theta_0^{(s)}$.
4: **Output** $\theta_{m+1}^{(s+1)} := \theta_{m+1}^{(s)}$.
5: **EndFor**
6: Choose $\theta_T$ uniformly randomly from $\{\theta_0^{(s)}\}_{s=0}^{S-1}$.

We emphasize that without this restarting strategy, Algorithm 1 still converges and the restarting loop in Algorithm 2 does not sacrifice the best-known complexity as stated in the next section.

### 4 Convergence Analysis

This section presents key properties of the hybrid stochastic policy gradient estimators as well as the theoretical convergence analysis and complexity estimate.

#### 4.1 Properties of the hybrid SPG estimator

Let $\mathcal{F}_t := \sigma (\tilde{B}, B_1, \tilde{B}_1, \cdots, B_{t-1}, \tilde{B}_{t-1})$ be the $\sigma$-field generated by all trajectories sampled up to the $t$-th iteration. For the sake of simplicity, we assume that $B = \tilde{B}$ but our analysis can be easily extended for the case $B \neq \tilde{B}$. Then, the hybrid SPG estimator $v_t$ has the following properties.

**Lemma 4.1** (Key properties). Let $v_t$ be defined as in (4) and $\Delta v_t := v_t - \nabla J(\theta_t)$. Then

$$E_{\tau \sim p_{\theta_t}} [v_t] = \nabla J(\theta_t) + \beta \Delta v_{t-1}. \quad (5)$$

If $\beta \neq 0$, then $v_t$ is an unbiased estimator. In addition, we have

$$E_{\tau \sim p_{\theta_t}} [||\Delta v_t||^2] \leq \beta^2 ||\Delta v_{t-1}||^2 + \frac{(1-\beta)^2 \sigma^2}{B} + \frac{\sqrt{C}}{B} \|\theta_t - \theta_{t-1}\|^2, \quad (6)$$

where $C > 0$ is a given constant.

The proof of Lemma 4.1 and the explicit constants are given in Supp. Doc. A.1 due to space limit.

#### 4.2 Complexity Estimates

The following lemma presents a key estimate for our convergence results.

**Lemma 4.2** (One-iteration analysis). Under Assumption 3.2, 3.3, and 3.4, let $\{\theta_t\}_{t=0}^{m}$ be the sequence generated by Algorithm 1 and $G_\eta$ be the gradient mapping defined in (3). Then

$$E [F(\theta_{t+1})] \leq E [F(\theta_t)] + \frac{\sigma^2}{2} E \left[ \|G_\eta(\theta_t)\|^2 \right] - \frac{\xi}{2} E \left[ ||v_t - \nabla J(\theta_t)||^2 \right] + \frac{\zeta}{2} E \left[ ||\theta_{t+1} - \theta_t||^2 \right], \quad (7)$$

where $\xi := \alpha (1 + 2\eta^2)$ and $\zeta := \alpha \left( \frac{\eta}{\tilde{c}} - L\alpha - 3 \right) > 0$ provided that $\alpha \in (0, 1)$ and $\frac{\eta}{\tilde{c}} - L\alpha - 3 > 0$.

The following theorem summarizes the convergence analysis of Algorithm 1.

**Theorem 4.1.** Under Assumption 3.1, 3.2, 3.3, and 3.4, let $\{\theta_t\}_{t=0}^{m}$ be the sequence generated by Algorithm 1 with

$$\begin{cases}
\beta := 1 - \frac{\sqrt{\beta}}{\sqrt{N(m+1)}} \\
\alpha := \frac{\sqrt{3} \sqrt{c} (m+1)^{3/4}}{2} \\
\eta := \frac{2}{\tilde{c} + L}\end{cases}, \quad (8)$$

where $B, \tilde{c}, L$, and $\tilde{c}$ are given constants. If $\tilde{\theta}_T$ is chosen uniformly at random from $\{\theta_t\}_{t=0}^{m}$, then the following estimate holds

$$E \left[ \|G_\eta(\tilde{\theta}_T)\|^2 \right] \leq \frac{3(4 + L)^2 \sigma^2}{4BN(m+1)^{3/2}} + \frac{(4 + L)^2 \sqrt{3\tilde{c}} N^{1/4}}{4\tilde{c}\sqrt{2} (B(m+1))^{3/4}} \left[ F^* - F(\theta_0) \right]. \quad (9)$$

Consequently, the trajectory complexity is presented in the following corollary.
Corollary 4.1. For both Algorithm 2 and Algorithm 3, let us fix $B \in \mathbb{N}_+$ and set $N := \tilde{c}B^{8/3} |B(m+1)|^{1/3}$ for some $\tilde{c} > 0$. If we also choose $m$ in Algorithm 1 such that $m+1 = \frac{\Psi(\sigma)}{B^2\epsilon^2}$ and choose $m, S$ in Algorithm 2 such that $S(m+1) = \frac{\Psi(\sigma)}{B^2\epsilon^2}$ for some constant $\Psi_0$, then the number of trajectories $T_{\text{traj}}$ to achieve $\hat{\theta}_T$ such that $\mathbb{E}[\|G(\hat{\theta}_T)\|^2] \leq \epsilon^2$ for any $\epsilon > 0$ is at most

$$T_{\text{traj}} = \mathcal{O}(\epsilon^{-3}).$$

where $\hat{\theta}_T$ is chosen uniformly at random from $\{\theta_t^{(s)}\}_{s=0,\ldots,S-1}$ if using Algorithm 2.

The proof of Theorem 4.1 and Corollary 4.1 are given in Supp. Doc. A.3 and A.4, respectively.

Comparing our complexity bound with other existing methods in Table 1, we can see that we improve a factor of $\epsilon^{-1/3}$ over SVRPG in Xu et al. (2019a) while matching the best-known complexity without the need of using the policy Hessian estimator as HAPG from Shen et al. (2019).

5 Numerical Experiments

In this section, we present three examples to provide comparison between the performance of HSPGA and other related policy gradient methods. We also provide an example to illustrate the effect of the regularizer $Q_1(\cdot)$ to our model (2). More examples can be found in the Supp. Doc. C. All experiments are run on a Macbook Pro with 2.3 GHz Quad-Core, 8GB RAM.

Figure 1: The performance of three algorithms on the CartPole-v0 environment.

We implement our restarting algorithm, Algorithm 2, on top of the rllab\textsuperscript{1} library (Duan et al., 2016). The source code is available at https://github.com/unc-optimization/ProxHSPGA. We compare our algorithm with two other methods: SVRPG \cite{Papini2018} and GPOMDP \cite{Xu2019a}.

\begin{itemize}
  \item \textbf{Cart Pole} which is available in OpenAI gym \cite{Brockman2016}, a well-known toolkit for developing and comparing reinforcement learning algorithms. We also test these algorithms on continuous control tasks using other simulators such as Roboschool \cite{Klimov2017} and Mujoco \cite{Todorov2012}.
\end{itemize}

For each environment, we initialize the policy randomly and use it as initial policies for all 10 runs of all algorithms. The performance measure, i.e., mean rewards, is computed by averaging the final rewards of 50 trajectories sampled by the current policy. We then compute the mean and 90% confidence interval across 10 runs of these performance measures at different time point. In all plots, the solid lines represent the mean and the shaded areas are the confidence band of the mean rewards. In addition, detailed configurations of the policy network and parameters can be found in Supp. Doc. B. We note that the architecture of the neural network is denoted as [observation space] $\times$ [hidden layers] $\times$ [action space].

Cart Pole-v0 environment: For the Cart pole environment, we use a deep soft-max policy network (Bridle, 1990; Levine, 2017; Sutton and Barto, 2018) with one hidden layer of 8 neurons. Figure 1 depicts the results where we run each algorithm for 10 times and compute the mean and 90% confidence intervals.

From Figure 1, we can see that HSPGA outperforms the other 2 algorithms while SVRPG works better than GPOMDP as expected. HSPGA is able to reach the maximum reward of 200 in less than 4000 episodes.

Mountain Car-v0 environment: For the Mountain Car-v0 environment, we use a deep Gaussian policy (Sutton and Barto, 2018) where the mean is the output of a neural network containing one hidden layer of 8 neurons and the standard deviation is fixed at 1. The results of three algorithms are presented in Figure 3.

We observe similar results as in the previous example where HSPGA has the best performance over three candidates. SVRPG is still better than GPOMDP in this example.

Acrobot environment: Next, we evaluate three algorithms on the Acrobot-v1 environment. Here, we use a deep soft-max policy with one hidden layer of 16 neurons. The performance of these 3 algorithms are illustrated in Figure 2.

We observe similar results as in the previous example where HSPGA has the best performance over three candidates. SVRPG is still better than GPOMDP in this example.

Mountain Car environment: For the MountainCar-v0 environment, we use a deep Gaussian policy (Sutton and Barto, 2018) where the mean is the output of a neural network containing one hidden layer of 8 neurons and the standard deviation is fixed at 1. The results of three algorithms are presented in Figure 3.

Figure 3 shows that HSPGA highly outperforms the other two algorithms. Again, SVRPG remains better than GPOMDP as expected.

The effect of regularizers: We test the effect of the regularizer $Q(\cdot)$ by adding a Tikhonov one as

$$\max_{\theta \in \mathbb{R}^d} \left\{ J(\theta) - \lambda \|\theta\|_2^2 \right\}.$$ 

This model was intensively studied in Liu et al. (2019).

We also compare all non-composite algorithms with ProxHSPGA in the Roboschool Inverted Pendulum-v1 environment. In this experiment, we set the penalty parameter $\lambda = 0.001$ for ProxHSPGA. The results are depicted in Figure 4 and more information about the configuration of each algorithm is in Supp. Document [3].

![RoboschoolInvertedPendulum-v1](image)

Figure 4: The performance of composite vs. non-composite algorithms on the Roboschool Inverted Pendulum-v1 environment.

From Figure 4 in terms of non-composite algorithms, HSPGA is the best followed by SVRPG and then by GPOMDP. Furthermore, ProxHSPGA shows its advantage by reaching the maximum reward of 1000 faster than HSPGA.

6 Conclusion

We have presented a novel policy gradient algorithm to solve regularized reinforcement learning models. Our algorithm uses a novel policy gradient estimator which is a combination of an unbiased estimator, i.e. REINFORCE estimator, and a biased estimator adapted from SARAH estimator for policy gradient. Theoretical results show that our algorithm achieves the best-known trajectory complexity to attain an $\varepsilon$-approximate first-order solution for the problem under standard assumptions. In addition, our numerical experiments not only help confirm the benefit of our algorithm compared to other closely related policy gradient methods but also verify the effectiveness of regularization in policy gradient methods.

A Hybrid Stochastic Policy Gradient Algorithm for Reinforcement Learning

SUPPLEMENTARY DOCUMENT

A Hybrid Stochastic Policy Gradient Algorithm for Reinforcement Learning

This supplementary document presents the full proofs of technical results presented in the main text. It also provides the details of our configurations for numerical experiments in Section 5.

A Convergence Analysis

We note that the original idea of using hybrid estimators has been proposed in our working paper [Tran-Dinh et al., 2019b]. In this work, we have extended this idea as well as the proof techniques for stochastic optimization in Tran-Dinh et al. (2019b) into reinforcement learning settings. We now provide the full analysis of Algorithm 1 and 2. We first prove a key property of our new hybrid estimator for the policy gradient \( \nabla J(\theta) \). Then, we provide the proof of Theorem 4.1 and Corollary 4.1.

A.1 Proof of Lemma 4.1: Bound on the Variance of the Hybrid SPG Estimator

Part of this proof comes from the proof of Lemma 1 in Tran-Dinh et al. (2019b). Let \( \mathbb{E}_{B, \hat{B}}[\cdot] := \mathbb{E}_{\tau \sim p_{\theta_t}[\cdot]} \) be the total expectation. Using the independence of \( \tau \) and \( \hat{\tau} \), taking the total expectation on (4), we obtain

\[
\mathbb{E}_{B, \hat{B}}[v_t] = \beta v_{t-1} + \beta [\nabla J(\theta_t) - \nabla J(\theta_{t-1})] + (1 - \beta) \nabla J(\theta_t) = \nabla J(\theta_t) + \beta [v_{t-1} - \nabla J(\theta_{t-1})],
\]

which is the same as (4).

To prove (5), we first define \( u_t := \frac{1}{B} \sum_{\hat{\tau} \in \hat{B}_t} g(\hat{\tau}|\theta_t) \) and \( \Delta u_t := u_t - \nabla J(\theta_t) \). We have

\[
\|\Delta v_t\|^2 = \beta^2 \|\Delta v_{t-1}\|^2 + \frac{\beta^2}{B^2} \left\| \sum_{\tau \in B_t} \Delta g(\tau|\theta_t) \right\|^2 + (1 - \beta)^2 \|\Delta u_t\|^2 + \beta^2 \|\nabla J(\theta_{t-1}) - \nabla J(\theta_t)\|^2 + 2\beta(1 - \beta)(\Delta v_{t-1})^T[u_t - \nabla J(\theta_t)] + \frac{2\beta(1 - \beta)}{B} \sum_{\tau \in B_t} [\Delta g(\tau|\theta_t)]^T(\Delta u_t).
\]

Taking the total expectation and note that \( \mathbb{E}_{\hat{B}}[u_t] := \mathbb{E}_{\hat{\tau} \sim p_{\theta_t}[\cdot]} = \nabla J(\theta_t) \) and \( \mathbb{E}_{\hat{B}}[\|u_t - \nabla J(\theta_t)\|^2] \leq \frac{1}{B^2} \sum_{\hat{\tau} \in \hat{B}} \mathbb{E}[\|g(\hat{\tau}|\theta_t) - \mathbb{E}[g(\hat{\tau}|\theta_t)]\|^2] = \frac{\sigma^2}{B^2} \), we get

\[
\mathbb{E}_{B, \hat{B}}[\|\Delta v_t\|^2] = \beta^2 \|\Delta v_{t-1}\|^2 + \frac{\beta^2}{B^2} \mathbb{E}_{B}[\left\| \sum_{\tau \in B_t} \Delta g(\tau|\theta_t) \right\|^2] + (1 - \beta)^2 \mathbb{E}_{\hat{B}}[\|\Delta u_t\|^2] - \beta^2 \|\nabla J(\theta_{t-1}) - \nabla J(\theta_t)\|^2 \leq \beta^2 \|\Delta v_{t-1}\|^2 + \frac{\beta^2}{B^2} \sum_{\tau \in B_t} \mathbb{E}_{B}[\|\Delta g(\tau|\theta_t)\|^2] - \beta^2 \|\nabla J(\theta_{t-1}) - \nabla J(\theta_t)\|^2 + \frac{(1 - \beta)^2}{B} \sigma^2 \leq \beta^2 \|\Delta v_{t-1}\|^2 + \frac{\beta^2}{B^2} \sum_{\tau \in B_t} \mathbb{E}_{B}[\|\Delta g(\tau|\theta_t)\|^2] + \frac{(1 - \beta)^2}{B} \sigma^2,
\]

where the first inequality comes from the triangle inequality then we ignore the non-negative terms to arrive at the second inequality.

Additionally, Lemma 6.1 in Xu et al. (2019a) shows that

\[
\text{Var}[\omega(\tau|\theta_t, \theta_{t-1})] \leq C_\omega \|\theta_t - \theta_{t-1}\|^2,
\]

(11)
where $C_\omega := H(2HG^2 + M)(W + 1)$.

Using (11) we have
\[
\mathbb{E}_B \left[ \|\Delta g(\tau | \theta_t)^2\| \right] = \mathbb{E}_B \left[ \|g(\tau | \theta_t) - \omega(\tau | \theta_t, \theta_{t-1})g(\tau | \theta_{t-1})\|^2 \right]
\]
\[
= \mathbb{E}_B \left[ \|1 - \omega(\tau | \theta_t, \theta_{t-1})g(\tau | \theta_{t-1}) + (g(\tau | \theta_t) - g(\tau | \theta_{t-1}))\|^2 \right]
\]
\[
\leq \mathbb{E}_B \left[ \|1 - \omega(\tau | \theta_t, \theta_{t-1})g(\tau | \theta_{t-1})\|^2 \right] + \mathbb{E}_B \left[ \|g(\tau | \theta_t) - g(\tau | \theta_{t-1})\|^2 \right]
\]
\[
\leq C^2 \mathbb{E}_B \left[ \|1 - \omega(\tau | \theta_t, \theta_{t-1})\|^2 \right] + L_g^2 \|\theta_t - \theta_{t-1}\|^2
\]
\[
\leq C^2 \mathbb{E}_B \left[ \|1 - \omega(\tau | \theta_t, \theta_{t-1})\|^2 \right] + L_g^2 \|\theta_t - \theta_{t-1}\|^2,
\]

where $L_g := \frac{HM(R+|b|)}{1-\gamma}$, $C_g := \frac{HG(R+|b|)}{1-\gamma}$, and $b$ is a baseline reward. Here, (*) comes from Lemma 3.1 and (**) is from Lemma 1 in [Cortes et al. 2010].

Plugging the last estimate into (10) yields
\[
\mathbb{E}_{B, \hat{b}} \left[ \|\Delta v_t\|^2 \right] \leq \beta^2 \|\Delta v_{t-1}\|^2 + \frac{\beta^2(C_g^2C_\omega + L_g^2)}{B} \|\theta_t - \theta_{t-1}\|^2 + \frac{(1 - \beta)^2}{B} \sigma^2,
\]
which is \[\bigstar\], where $\mathcal{C} := C_g^2C_\omega + L_g^2$.

A.2 Proof of Lemma 4.2: Key Estimate of Algorithm 1

Similar to the proof of Lemma 5 in [Tran-Dinh et al. 2019b], from the update in Algorithm 1, we have $\theta_{t+1} = (1 - \gamma)\theta_t + \gamma \theta_{t-1}$, which leads to $\theta_{t+1} - \theta_t = \gamma (\theta_{t-1} - \theta_t)$. Combining this expression and the $L$-smoothness of $J(\theta)$ in Lemma 3.1, we have
\[
J(\theta_{t+1}) \geq J(\theta_t) + \left[ \nabla J(\theta_t) \right]^\top (\theta_{t+1} - \theta_t) - \frac{L}{2} \|\theta_{t+1} - \theta_t\|^2
\]
\[
= J(\theta_t) + \alpha \left[ \nabla J(\theta_t) \right]^\top (\theta_{t+1} - \theta_t) - \frac{L\alpha^2}{2} \|\theta_{t+1} - \theta_t\|^2.
\]

From the convexity of $Q$, we have
\[
Q(\theta_{t+1}) \leq (1 - \alpha)Q(\theta_t) + \alpha Q(\hat{\theta}_{t+1}) \leq Q(\theta_t) + \alpha \nabla Q(\hat{\theta}_{t+1})^\top (\hat{\theta}_{t+1} - \theta_t),
\]
where $\nabla Q(\hat{\theta}_{t+1})$ is a subgradient of $Q$ at $\hat{\theta}_{t+1}$.

By the optimality condition of $\hat{\theta}_{t+1} = \mathrm{prox}_{\eta Q}(\theta_t + \eta v_t)$, we can show that $\nabla Q(\hat{\theta}_{t+1}) = v_t - \frac{1}{\eta}(\hat{\theta}_{t+1} - \theta_t)$ for some $\nabla Q(\hat{\theta}_{t+1}) \in \partial Q(\hat{\theta}_{t+1})$ where $\partial Q$ is the subdifferential of $Q$ at $\hat{\theta}_{t+1}$. Plugging this into (14), we get
\[
Q(\theta_{t+1}) \leq Q(\theta_t) + \alpha v_t^\top (\hat{\theta}_{t+1} - \theta_t) - \frac{\alpha}{\eta} \|\hat{\theta}_{t+1} - \theta_t\|^2.
\]

Subtracting (15) from (13), we obtain
\[
F(\theta_{t+1}) \geq F(\theta_t) + \alpha \left[ v_t - \nabla J(\theta_t) \right]^\top (\hat{\theta}_{t+1} - \theta_t) + \left( \frac{\alpha}{\eta} - \frac{L\alpha^2}{2} \right) \|\hat{\theta}_{t+1} - \theta_t\|^2
\]
\[
= F(\theta_t) - \alpha \left[ v_t - \nabla J(\theta_t) \right]^\top (\hat{\theta}_{t+1} - \theta_t) + \left( \frac{\alpha}{\eta} - \frac{L\alpha^2}{2} \right) \|\hat{\theta}_{t+1} - \theta_t\|^2.
\]
and ignoring the non-negative term $\frac{1}{2} \|v_t - \nabla J(\theta_t) - (\hat{\theta}_{t+1} - \theta_t)\|^2$, we can rewrite (16) as

$$F(\theta_{t+1}) \geq F(\theta_t) - \frac{\alpha}{2} \|\nabla J(\theta_t) - v_t\|^2 + \left(\frac{\alpha}{\eta} - \frac{\alpha \sigma^2}{2} - \frac{\alpha}{2}\right) \|\hat{\theta}_{t+1} - \theta_t\|^2.$$  

Taking the total expectation over the entire history $F_{t+1}$, we obtain

$$\mathbb{E}[F(\theta_{t+1})] \geq \mathbb{E}[F(\theta_t)] - \frac{\alpha}{2} \mathbb{E}[\|\nabla J(\theta_t) - v_t\|^2] + \left(\frac{\alpha}{\eta} - \frac{\alpha \sigma^2}{2} - \frac{\alpha}{2}\right) \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2].$$  

Taking the full expectation over the entire history $F_{t+1}$ yields

$$\eta^2 \mathbb{E}[G_\eta(\theta_t)]^2 \leq 2 \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2] + 2 \eta^2 \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2].$$

Multiply this inequality by $-\frac{\alpha}{2}$ and add to (17), we arrive at

$$\mathbb{E}[F(\theta_{t+1})] \geq \mathbb{E}[F(\theta_t)] + \frac{\eta^2}{2} \mathbb{E}[\|G_\eta(\theta_t)\|^2] - \frac{\eta}{2} \left(1 + 2 \eta^2\right) \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] + \frac{\eta}{2} \left(\frac{\alpha}{\eta} - L\alpha - 3\right) \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2],$$

which can be rewritten as

$$\mathbb{E}[F(\theta_{t+1})] \geq \mathbb{E}[F(\theta_t)] + \frac{\eta^2}{2} \mathbb{E}[\|G_\eta(\theta_t)\|^2] - \frac{\eta}{2} \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] + \frac{\eta}{2} \left(\frac{\alpha}{\eta} - L\alpha - 3\right) \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2] + \frac{1-\beta^2}{B} \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] + \frac{(1-\beta^2)\sigma^2}{B},$$

where $\xi := \alpha(1 + 2\eta^2)$ and $\zeta := \alpha \left(\frac{\alpha}{\eta} - L\alpha - 3\right)$ which is exactly (7).

### A.3 Proof of Theorem 4.1 Key Bound on the Gradient Mapping

Firstly, using the identity $\theta_{t+1} - \theta_t = \gamma(\hat{\theta}_{t+1} - \theta_t)$, taking the total expectation over the entire history $F_{t+1}$, we can rewrite (6) as

$$\mathbb{E}[\|v_{t+1} - \nabla J(\theta_{t+1})\|^2] \leq \beta^2 \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] + \frac{\alpha \sigma^2}{B} \mathbb{E}[\|\theta_{t+1} - \theta_t\|^2] + \frac{1-\beta^2}{B} \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2].$$

Multiply (18) by $-\frac{\kappa}{2}$ for some $\kappa > 0$, then add to (7), we have

$$\mathbb{E}[F(\theta_{t+1})] - \frac{\kappa}{2} \mathbb{E}[\|v_{t+1} - \nabla J(\theta_{t+1})\|^2] 
\geq \mathbb{E}[F(\theta_t)] - \frac{(\kappa \beta^2 + \kappa \sigma^2)}{2} \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] + \frac{\alpha \sigma^2}{2} \mathbb{E}[\|G_\eta(\theta_t)\|^2] + \frac{\kappa}{2} \left(\zeta - \frac{\kappa \beta^2 \sigma^2}{B}\right) \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2] 
- \frac{\kappa (1-\beta^2) \sigma^2}{2B} 
= \mathbb{E}[F(\theta_t)] - \frac{\kappa}{2} \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] + \frac{\alpha \sigma^2}{2} \mathbb{E}[\|G_\eta(\theta_t)\|^2] - \frac{\kappa}{2B} \left(\zeta - \kappa(1-\beta^2)\right) \mathbb{E}[\|v_t - \nabla J(\theta_t)\|^2] 
+ \frac{\kappa}{2} \left(\zeta - \frac{\kappa \beta^2 \sigma^2}{B}\right) \mathbb{E}[\|\hat{\theta}_{t+1} - \theta_t\|^2] - \frac{\kappa (1-\beta^2) \sigma^2}{2B}. $$
Let us define $F(\theta_t) := E[F(\theta_t)] - \frac{\kappa}{2} E \left[ \|v_t - \nabla J(\theta_{t+1})\|^2 \right]$. Then, the last inequality can be written as

$$F(\theta_{t+1}) \geq F(\theta_t) + \frac{\kappa^2}{2} E \left[ \|G_\eta(\theta)_t\|^2 \right] - \frac{\kappa(1-\beta^2)\sigma^2}{2B} + \frac{1}{2} \left( \zeta - \frac{\kappa^2 C\alpha}{B} \right) E \left[ \|\theta_{t+1} - \theta_t\|^2 \right].$$

(19)

Suppose that $\eta, \alpha, \beta$ are chosen such that

$$\frac{2}{\eta} - La - 3 \geq \frac{\kappa^2 C\alpha}{B} > 0 \quad \text{and} \quad \alpha(1 + 2\eta^2) \leq \kappa(1 - \beta^2).$$

(20)

Then, we have $\zeta \geq \frac{\kappa^2 C\alpha}{B}$ and $\zeta \leq \kappa(1 - \beta^2)$. By ignoring the non-negative terms in (19), we can rewrite it as

$$F(\theta_{t+1}) \geq F(\theta_t) + \frac{\eta^2 \alpha}{2} E \left[ \|G_\eta(\theta)_t\|^2 \right] - \frac{\kappa(1 - \beta^2)\sigma^2}{2B}.$$  

Summing the above inequality for $t = 0, \cdots, m$, we obtain

$$F(\theta_{m+1}) \geq F(\theta_0) + \frac{\eta^2 \alpha}{2} \sum_{t=0}^m E \left[ \|G_\eta(\theta)_t\|^2 \right] - \frac{\kappa(m + 1)(1 - \beta^2)\sigma^2}{\eta^2 \alpha B}.$$  

(21)

Rearranging terms and multiply both sides by $\frac{2}{\eta^2 \alpha}$, (21) becomes

$$\sum_{t=0}^m E \left[ \|G_\eta(\theta)_t\|^2 \right] \leq \frac{2}{\eta^2 \alpha} \left[ F(\theta_{m+1}) - F(\theta_0) \right] + \frac{\kappa(m + 1)(1 - \beta^2)\sigma^2}{\eta^2 \alpha B}.$$  

(22)

Note that

$$F(\theta_0) = F(\theta_0) - \frac{\kappa}{2} E \left[ \|v_t - \nabla J(\theta_0)\|^2 \right] \geq F(\theta_0) - \frac{\kappa \sigma^2}{2N},$$

and $F(\theta_{m+1}) = F(\theta_{m+1}) - \frac{\kappa}{2} E \left[ \|v_{m+1} - \nabla J(\theta_{m+1})\|^2 \right] \leq F(\theta_{m+1})$. Using these estimate in (22), we obtain

$$\sum_{t=0}^m E \left[ \|G_\eta(\theta)_t\|^2 \right] \leq \frac{2}{\eta^2 \alpha} \left[ F(\theta_{m+1}) - F(\theta_0) \right] + \frac{\kappa \sigma^2}{\eta^2 \alpha N} + \frac{(m + 1)(1 - \beta^2)\sigma^2}{\eta^2 \alpha B}.$$  

(23)

Multiplying both sides by $\frac{1}{m+1}$, we have

$$\frac{1}{m+1} \sum_{t=0}^m E \left[ \|G_\eta(\theta)_t\|^2 \right] \leq \frac{2}{\eta^2 \alpha (m + 1)} \left[ F(\theta_{m+1}) - F(\theta_0) \right] + \frac{\kappa \sigma^2}{\eta^2 \alpha \left( \frac{1}{N(m + 1)} + \frac{1 - \beta^2}{B} \right)}.$$  

Now we choose $\beta := 1 - \frac{\sqrt{B}}{\sqrt{N(m+1)}}$ so that the right-hand side of (23) is minimized. Note that if $1 \leq B \leq N(m+1)$, then $\beta \in [0, 1)$.

Let us choose $\eta := \frac{2}{\sqrt{L} \alpha} \leq \frac{1}{2}$ which means $\zeta := \frac{2}{\eta} - La - 3 = 1$. We can satisfy the first condition of (20) by choosing $0 < \alpha \leq \frac{B}{\kappa \sigma^2}$.

Besides, the second condition in (20) holds if $0 < \alpha \leq \frac{\kappa(1 - \beta^2)}{1 + 2\eta^2}$. Since we have $\eta \leq \frac{1}{2}$ which leads to $1 + 2\eta^2 \leq \frac{3}{2}$ and using $1 - \beta^2 \geq 1 - \beta = \frac{B^{1/2}}{N^{1/2}(m+1)^{1/2}}$ we derive the condition for $\alpha$ as

$$0 < \alpha \leq \frac{2\kappa \sqrt{B}}{3\sqrt{N(m + 1)}}.$$  

Therefore, the overall condition for $\alpha$ is given as

$$0 < \alpha \leq \min \left\{ 1, \frac{B}{\kappa \sigma^2}, \frac{2\kappa \sqrt{B}}{3\sqrt{N(m + 1)}} \right\}.$$
If we choose $\kappa := \frac{\sqrt{3}N B(m+1)^{1/4}}{\sqrt{2C}}$, then we can update $\alpha$ as

$$\alpha := \frac{\hat{c} \sqrt{2} B^{3/4}}{\sqrt{3C} [N(m + 1)]^{1/4}}. \quad (24)$$

Using $1 \leq B \leq N(m + 1)$, we can bound $\alpha \leq \hat{c} \frac{2B}{3C}$, then we can choose $\hat{c} \in \left(0, \frac{3C}{2B}\right)$ so that $\gamma \in (0, 1]$.

With all the choices of $\beta$, $\eta$, $\alpha$, and $\kappa$ above, if we let the output $\tilde{\theta}_T$ be selected uniformly at random from $\{\theta_t\}_{t=0}^m$, then we have

$$\mathbb{E} \left[ \|G_\eta(\tilde{\theta}_T)\|^2 \right] = \frac{1}{m+1} \sum_{t=0}^m \mathbb{E} \left[ \|G_\eta(\theta_t)\|^2 \right]$$

$$\leq \frac{\sqrt{3C} N^{1/4}}{\eta^2 \hat{c} \sqrt{2} [B(m + 1)]^{3/4}} \|F(\theta_{m+1}) - F(\theta_0)\| + \frac{3\sigma^2}{\eta^2 [BN(m + 1)]^{1/2}}. \quad (25)$$

Note that $\eta = \frac{2}{\pi \kappa \alpha}$ and since $\alpha \leq 1$ we have $\frac{1}{\eta} \leq \frac{(4 + L)^2}{4}$. Plugging these into (25), we obtain

$$\mathbb{E} \left[ \|G_\eta(\tilde{\theta}_T)\|^2 \right] = \frac{1}{m+1} \sum_{t=0}^m \mathbb{E} \left[ \|G_\eta(\theta_t)\|^2 \right]$$

$$\leq \frac{(4 + L)^2 \sqrt{3C} N^{1/4}}{4 \hat{c} \sqrt{2} [B(m + 1)]^{3/4}} \|F(\theta_{m+1}) - F(\theta_0)\| + \frac{3(4 + L)^2 \sigma^2}{4[BN(m + 1)]^{1/2}}. \quad (26)$$

where we use the fact that $F(\theta_{m+1}) \leq F^*$.

### A.4 Proof of Corollary 4.1 Trajectory Complexity Bound of Algorithm 1 and Algorithm 2

If we fix a batch size $B \in \mathbb{N}_+$ and choose $N := \hat{c} \sigma^{8/3} [B(m + 1)]^{1/3}$ for some $\hat{c} > 0$, (26) is equivalent to

$$\mathbb{E} \left[ \|G_\eta(\tilde{\theta}_T)\|^2 \right] \leq \frac{(4 + L)^2 \sqrt{3C} \hat{c}^{1/4} \sigma^{2/3}}{4 \hat{c} \sqrt{2} [B(m + 1)]^{2/3}} \left[ F^* - F(\tilde{\theta}_T(0))\right] + \frac{3(4 + L)^2 \sigma^2}{4[Bn(m + 1)]^{1/2}} \frac{\sigma^{2/3}}{[B(m + 1)]^{2/3}}$$

$$= \frac{\Psi_0 \sigma^{2/3}}{[B(m + 1)]^{2/3}}. \quad (27)$$

where we define

$$\Psi_0 := \left[ \frac{(4 + L)^2 \sqrt{3C} \hat{c}^{1/4}}{4 \hat{c} \sqrt{2}} \right] \left[ F^* - F(\tilde{\theta}_T(0))\right] + \frac{3(4 + L)^2}{4 \hat{c}^{1/2}}. \quad (27)$$

Therefore, for any $\varepsilon > 0$, to guarantee $\mathbb{E} \left[ \|G_\eta(\tilde{\theta}_T)\|^2 \right] \leq \varepsilon^2$, we need $\frac{\Psi_0 \sigma^{2/3}}{[B(m + 1)]^{2/3}} = \varepsilon^2$ which leads to the total number of iterations

$$T = m + 1 = \frac{\Psi_0^{3/2} \sigma}{B \varepsilon^3} = O \left( \frac{1}{\varepsilon^3} \right).$$

The total number of proximal operations $\text{prox}_{\Psi_0 \sigma}$ is also $O \left( \frac{1}{\varepsilon^3} \right)$. In addition, the total number of trajectories is at most

$$N + 2B(m + 1) = \hat{c} \sigma^{8/3} [B(m + 1)]^{1/3} + \frac{2\Psi_0 \sigma}{\varepsilon}$$

$$= \hat{c} \sigma^{8/3} \Psi_0^{1/3} \sigma^{1/3} \frac{1}{\varepsilon} + \frac{2\Psi_0 \sigma}{\varepsilon^3}$$

$$= O \left( \frac{1}{\varepsilon^3} \right).$$
This proves our the complexity of Algorithm 1.

Next, let us denote the superscript \( (s) \) when the current stage is \( s \) for \( s = 0, \ldots, S - 1 \). Note that from the first inequality of (26), for any stage \( s = 0, \ldots, S - 1 \), the following holds

\[
\frac{1}{m + 1} \sum_{t=0}^{m} \mathbb{E} \left[ \|G_t(\theta_t(s))\|^2 \right] \leq \frac{(4 + L)^2 3CN^{1/4}}{4c(m + 1) \sqrt{B(m + 1)}^{3/4}} \left[ F(\theta_{m+1}^{(s)}) - F(\theta_{0}^{(s)}) \right] + \frac{3(4 + L)^2 \sigma^2}{4[BN(m + 1)]^{1/2}}.
\]

Summing for \( s = 0, \ldots, S - 1 \) and multiply both sides by \( \frac{1}{S} \) yields

\[
\frac{1}{S(m+1)} \sum_{s=0}^{S-1} \sum_{t=0}^{m} \mathbb{E} \left[ \|G_t(\theta_t(s))\|^2 \right] \leq \frac{(4 + L)^2 3C^1/4}{4c2[B(m + 1)]^{2/3}S} \left[ \frac{F^* - F(\theta_{0}^{(s)})}{\epsilon} \right] + \frac{3(4 + L)^2 \sigma^2/3}{4[BN(m + 1)]^{2/3}S} \left[ F^* - F(\theta_{0}^{(s)}) \right] + \frac{3(4 + L)^2 \sigma^2}{4[BN(m + 1)]^{1/2}}
\]

where we use \( F(\theta_{m+1}^{(S-1)}) \leq F^* \) again.

If we also fix a batch size \( B \in \mathbb{N}_+ \) and choose \( N := \tilde{c} \sigma^8/3 [B(m + 1)]^{1/3} \) for some \( \tilde{c} > 0 \), and select \( \tilde{\theta}_T \) uniformly random from \( \{\theta_t^{(s)}\}_{t=0,\ldots,S} \), then, similar to (3.4), (28) can be written as

\[
\mathbb{E} \left[ \|G_t(\tilde{\theta}_T)\|^2 \right] = \frac{1}{S(m+1)} \sum_{s=0}^{S-1} \sum_{t=0}^{m} \mathbb{E} \left[ \|G_t(\theta_t^{(s)})\|^2 \right] \leq \frac{(4 + L)^2 3C^1/4}{4c2[B(m + 1)]^{2/3}S} \left[ F^* - F(\theta_{0}^{(s)}) \right] + \frac{3(4 + L)^2 \sigma^2/3}{4[BN(m + 1)]^{2/3}S} \left[ F^* - F(\theta_{0}^{(s)}) \right] + \frac{3(4 + L)^2 \sigma^2}{4[BN(m + 1)]^{1/2}}
\]

where we use \( \Psi_0 \) defined in (21) and \( \frac{1}{S} \leq \frac{1}{S^{2/3}} \) for any \( S \geq 1 \).

Therefore, to guarantee \( \mathbb{E} \left[ \|G_t(\tilde{\theta}_T)\|^2 \right] \leq \epsilon^2 \) for any \( \epsilon > 0 \), we need \( \frac{\Psi_0 \sigma_0^2/3}{[B(m + 1)]^{2/3}} = \epsilon^2 \) which leads to the total number of iterations

\[
T = S(m + 1) = \frac{\Psi_0^2/3}{B \epsilon^2} = \mathcal{O} \left( \frac{1}{\epsilon^2} \right).
\]

The total number of proximal operations \( \text{prox}_{\sigma_0^2/3} \) is also \( \mathcal{O} \left( \frac{1}{\epsilon^2} \right) \). In addition, the total number of trajectories is at most

\[
S \left[ N + 2B(m + 1) \right] = S \left[ \tilde{c} \sigma^8/3 [B(m + 1)]^{1/3} + \frac{2 \Psi_0 \sigma}{\epsilon^3} \right]
\]

\[
= S \left[ \tilde{c} \sigma^8/3 \Psi_0^{1/3} \sigma^{1/3} + \frac{2 \Psi_0 \sigma}{\epsilon^3} \right]
\]

\[
= \mathcal{O} \left( \frac{1}{\epsilon^3} \right) + \mathcal{O} \left( \frac{1}{\epsilon^3} \right), \text{ for any } S \geq 1.
\]

Hence, we obtain the conclusion of Corollary 4.1.

\[ \square \]

**B Configurations of Algorithms in Section 5**

Let us describe in detail the configuration of our experiments in Section 5. We set \( \beta := 0.99 \) for HSPGA and \( \alpha := 0.99 \) for ProxHSPGA in all experiments. To choose the learning rate, we conduct a grid search over different choices. For Acrobot-v1, Cart pole-v0, and Mountain Car-v0 environments, we use the grid containing \{0.0005, 0.001, 0.0025, 0.005, 0.0075, 0.01\}. Meanwhile, we use \{0.0005, 0.00075, 0.001, 0.0025, 0.005\} for the remaining environments. The snapshot batch-sizes are also chosen from \{10, 25, 50, 100\} while the mini-batch sizes are selected from \{3, 5, 10, 15, 20, 25\}. More details about the selected parameters for each experiment are shown in Table 2.
Table 2: The configuration of different algorithms on discrete and continuous control environments

| Environment         | Algorithm  | Policy Network | Discount Factor γ | Trajectory Length H | Minibatch Size | Snapshot Batchsize | Learning Rate | Epoch Length m |
|---------------------|------------|----------------|-------------------|---------------------|----------------|-------------------|---------------|----------------|
| CartPole-v0         | GPOMDP     | $4 \times 8 \times 2$ | 0.99             | 200           | 10             | 10$^{-3}$         | 3             |
|                     | SVRPG      |                |                   |                     | 10             | 5$^{-3}$          | 3             |
|                     | HSPGA      |                |                   |                     | 5              | 5$^{-3}$          | 3             |
| Acrobot-v1          | GPOMDP     | $6 \times 16 \times 3$ | 0.999            | 500          | 10             | 2.5$^{-3}$        | 3             |
|                     | SVRPG      |                |                   |                     | 5              | 5$^{-3}$          | 3             |
|                     | HSPGA      |                |                   |                     | 3              | 5$^{-3}$          | 3             |
| MoutainCar-v0       | GPOMDP     | $2 \times 8 \times 1$ | 0.999            | 1000         | 10             | 5$^{-3}$          | 3             |
|                     | SVRPG      |                |                   |                     | 5              | 5$^{-3}$          | 3             |
|                     | HSPGA      |                |                   |                     | 5              | 5$^{-3}$          | 3             |
| MountainCar-v0      | GPOMDP     | $5 \times 16 \times 1$ | 0.999            | 1000         | 20             | 10$^{-3}$         | 3             |
|                     | SVRPG      |                |                   |                     | 5              | 5$^{-3}$          | 3             |
|                     | HSPGA      |                |                   |                     | 5              | 5$^{-3}$          | 3             |
|                     | ProxHSPGA  |                |                   |                     | 5              | 5$^{-3}$          | 3             |
| Swimmer-v2          | GPOMDP     | $8 \times 32 \times 32 \times 2$ | 0.99             | 500         | 50             | 5$^{-4}$          | 3             |
|                     | SVRPG      |                |                   |                     | 5              | 5$^{-4}$          | 3             |
|                     | HSPGA      |                |                   |                     | 5              | 5$^{-4}$          | 3             |
|                     | ProxHSPGA  |                |                   |                     | 5              | 5$^{-4}$          | 3             |
| Hopper-v2           | GPOMDP     | $11 \times 32 \times 32 \times 3$ | 0.99             | 500         | 50             | 5$^{-4}$          | 3             |

C Additional Numerical Results

Due to space limit in the main text, we show here another evidence on the effect of regularizers to policy optimization problems by carrying out an additional example on other continuous control tasks in Mujoco. The results are presented in Figure 5.

Figure 5: The performance of 4 algorithms on the composite vs. the non-composite settings using several Mujoco environments.

Again, Figure 5 still reveals the benefit of adding a regularizer, which potentially gains more reward than without using regularizer. We believe that the choice of regularizer is also critical and may lead to different performance. We refer to (Liu et al., 2019) for more evidence of using regularizers in reinforcement learning.
