TOWARDS OPTIMAL TRANSPORT FOR QUANTUM DENSITIES

EMANUELE CAGLIOTI, FRANÇOIS GOLSE, AND THIERRY PAUL

Abstract. An analogue of the quadratic Wasserstein (or Monge-Kantorovich) distance between Borel probability measures on \( \mathbb{R}^d \) has been defined in [F. Golse, C. Mouhot, T. Paul: Commun. Math. Phys. 343 (2015), 165–205] for density operators on \( L^2(\mathbb{R}^d) \), and used to estimate the convergence rate of various asymptotic theories in the context of quantum mechanics. The present work proves a Kantorovich type duality theorem for this quantum variant of the Monge-Kantorovich or Wasserstein distance, and discusses the structure of optimal quantum couplings. Specifically, we prove that optimal quantum couplings involve a gradient type structure similar to the Brenier transport map (which is the gradient of a convex function), or more generally, to the subdifferential of a l.s.c. convex function as in the Knott-Smith optimality criterion (see Theorem 2.12 in [C. Villani: “Topics in Optimal Transportation”, Amer. Math. Soc. 2003]).

1. Introduction

Let \( \mu, \nu \in \mathcal{P}(\mathbb{R}^d) \) (the set of Borel probability measures on \( \mathbb{R}^d \)). Given a l.s.c. function \( C : \mathbb{R}^d \times \mathbb{R}^d \to [0, +\infty] \), the Monge problem in optimal transport is to minimize the functional
\[
I_C[T] = \int_{\mathbb{R}^d} C(x, T(x)) \mu(dx) \in [0, +\infty]
\]
over the set of Borel maps \( T : \mathbb{R}^d \to \mathbb{R}^d \) such that \( \nu = T\#\mu \) (the push-forward measure of \( \mu \) by \( T \)). Here \( C(x, y) \) represents the cost of transporting the point \( x \) to the point \( y \), so that \( I_C[T] \) represents the total cost of transporting the probability \( \mu \) on \( \nu \) by the map \( T \). An optimal transport map \( T \) may fail to exist in full generality, so that one considers instead the following relaxed variant of the Monge problem, known as the Kantorovich problem:
\[
\inf_{\pi \in \Pi(\mu, \nu)} \int_{\mathbb{R}^d \times \mathbb{R}^d} C(x, y) \pi(dx, dy).
\]
Here, \( \Pi(\mu, \nu) \) is the set of couplings of \( \mu \) and \( \nu \), i.e. the set of Borel probability measures on \( \mathbb{R}^d \times \mathbb{R}^d \) such that
\[
\int_{\mathbb{R}^d \times \mathbb{R}^d} (\phi(x) + \psi(y)) \pi(dx, dy) = \int_{\mathbb{R}^d} \phi(x) \mu(dx) + \int_{\mathbb{R}^d} \psi(y) \nu(dy)
\]
for all \( \phi, \psi \in C_b(\mathbb{R}^d) \) (where \( C_b(\mathbb{R}^d) \) designates the set of bounded and continuous real-valued functions defined on \( \mathbb{R}^d \)). An optimal coupling \( \pi_{\text{opt}} \) always exists, so that the inf is always attained in the Kantorovich problem (see Theorem 1.3 in

2020 Mathematics Subject Classification. 49Q22, 81C99 (35Q93).
Key words and phrases. Wasserstein distance, Kantorovich duality, Quantum density operators, Quantum couplings, Optimal transport.
or Theorem 4.1 in [24]). Of course, if an optimal map $T$ exists for the Monge problem, the push-forward of the measure $\mu$ by the map $x \mapsto (x, T(x))$, which can be (informally) written as

$$\pi(dx dy) := \mu(dx) \delta_{T(x)}(dy)$$

is an optimal coupling for the Kantorovich problem.

In the special case where $C(x, y) = |x-y|^2$ (the square Euclidean distance between $x$ and $y$)

$$\inf_{\pi \in \Pi(\mu, \nu)} \sqrt{\int_{\mathbb{R}^d \times \mathbb{R}^d} |x-y|^2 \pi(dx dy)} = \text{dist}_{MK, 2}(\mu, \nu)$$

is a distance on

$$\mathcal{P}_2(\mathbb{R}^d) := \left\{ \mu \in \mathcal{P}(\mathbb{R}^d) \text{ s.t. } \int_{\mathbb{R}^d} |x|^2 \mu(dx) < \infty \right\},$$

referred to as the Monge-Kantorovich, or the Wasserstein distance of exponent 2 (see chapter 7 in [23], or chapter 6 in [24], or chapter 7 in [1]). In that case, there is “almost” an optimal transport map, in the following sense: $\pi \in \Pi(\mu, \nu)$ is an optimal coupling for the Kantorovich problem if and only if there exists a proper convex l.s.c. function $a : \mathbb{R}^d \to \mathbb{R} \cup \{+\infty\}$ such that

$$\text{supp}(\pi) \subset \text{graph}(\partial a)$$

(where $\partial a$ denotes the subdifferential of $a$). This is the Knott-Smith optimality criterion [17] (Theorem 2.12 (i) in [23]). If $\mu$ satisfies the condition

$$B \text{ is Borel measurable and } \mathcal{H}^{d-1}(B) < \infty \implies \mu(B) = 0,$$

there exists a unique optimal coupling $\pi$ of the form (1) for the Kantorovich problem, with $T = \nabla a$, where $a$ is a proper convex l.s.c. function\(^2\) on $\mathbb{R}^d$. (In condition (2), the notation $\mathcal{H}^{d-1}(B)$ designates the $d-1$-dimensional measure of $B$.) This is the Brenier optimal transport theorem [4] (stated as Theorem 2.12 (ii) in [23]). It allows recasting (1) as

$$\int_{\mathbb{R}^d} (y - \nabla a(x)) \pi(dx dy) = 0,$$

and the a.e. defined map $\nabla a$ is referred to as the “Brenier optimal transport map”.

Integrating $\pi$ against a test function depending only on $x$ shows that $\nabla a$ transports the $x$-marginal $\mu$ of $\pi$ to its $y$-marginal $\nu$, i.e.

$$\nu = \nabla a \# \mu.$$

(This equality can obviously be deduced from (1) as well.)

Recently, an analogue of the Monge-Kantorovich-Wasserstein distance $\text{dist}_{MK, 2}$ has been defined in [11] on the set $\mathcal{D}(\mathcal{H})$ of density operators on the Hilbert space $\mathcal{H} := L^2(\mathbb{R}^d)$. (Recall that a density operator on $\mathcal{H}$ is a linear operator $R$ on $\mathcal{H}$ such that $R = R^* \geq 0$ and $\text{trace}(R) = 1$.) This definition is based on the following well known correspondence between classical and quantum paradigms.

(a) Bounded continuous functions $f \equiv f(q, p)$ on the phase space $\mathbb{R}_q^d \times \mathbb{R}_p^d$ should be put in correspondence with bounded operators on the Hilbert space $\mathcal{H} = L^2(\mathbb{R}_q^d)$ of square-integrable functions defined on the configuration space $\mathbb{R}_q^d$.

\(^1\)I.e. not identically equal to $+\infty$.
\(^2\)In particular $\nabla a$ is defined a.e. on $\mathbb{R}^d$. 
(b) The (Lebesgue) integral of (integrable) functions on \( \mathbb{R}_q^d \times \mathbb{R}_p^d \) should be replaced by the trace of (trace-class) operators on \( \mathfrak{F} \).

c The coordinates \( q_j \) (for \( j = 1, \ldots , d \)) on the null section of the phase space \( \mathbb{R}_q^d \times \mathbb{R}_p^d \) should be put in correspondence with the (unbounded) self-adjoint operators \( Q_j \) on \( \mathfrak{F} \) defined by

\[
\text{Dom}(Q_j) := \left\{ \psi \in \mathfrak{F} \text{ s.t. } \int_{\mathbb{R}^d} q_j^2 |\psi(q)|^2 dq < \infty \right\}, \quad (Q_j \psi)(q) := q_j \psi(q)
\]

for all \( j = 1, \ldots , d \).

d The coordinates \( p_j \) (for \( j = 1, \ldots , d \)) on the fibers of the phase space \( \mathbb{R}_q^d \times \mathbb{R}_p^d \) should be put in correspondence with the (unbounded) self-adjoint operators \( P_j \) on \( \mathfrak{F} \) defined by

\[
\text{Dom}(P_j) := \left\{ \psi \in \mathfrak{F} \text{ s.t. } \int_{\mathbb{R}^d} |\partial_{q_j} \psi(q)|^2 dq < \infty \right\}, \quad (P_j \psi)(q) := -i \hbar \partial_{q_j} \psi(q)
\]

for all \( j = 1, \ldots , d \).

e The first order differential operators \( f \mapsto \{q_j, f\} \) and \( f \mapsto \{p_j, f\} \), where \( \{\cdot, \cdot\} \) is the Poisson bracket on \( \mathbb{R}_q^d \times \mathbb{R}_p^d \) such that

\[
\{p_j, p_k\} = \{q_j, q_k\} = 0, \quad \{p_j, q_k\} = \delta_{jk} \quad \text{for } j, k = 1, \ldots , d
\]

should be replaced with the derivations on \( \mathcal{L}(\mathfrak{F}) \) (the algebra of bounded linear operators on \( \mathfrak{F} \)) defined by

\[
A \mapsto \frac{i}{\hbar} [Q_j, A] \quad \text{and} \quad A \mapsto \frac{i}{\hbar} [P_j, A]
\]

for \( j = 1, \ldots , d \).

Following these principles, the quadratic transport cost from \( (x, \xi) \) to \( (y, \eta) \) in \( \mathbb{R}^d \times \mathbb{R}^d \) should be replaced with the differential operator on \( \mathbb{R}_q^d \times \mathbb{R}_p^d \)

\[
C := \sum_{j=1}^{d} ((x_j - y_j)^2 - \hbar^2 (\partial_{x_j} - \partial_{y_j})^2).
\]

Henceforth we denote by \( H \) the Hamiltonian

\[
H := \sum_{j=1}^{d} (Q_j^2 + P_j^2) = |x|^2 - \hbar^2 \Delta_x
\]

of the quantum harmonic oscillator. Given \( R, S \in \mathcal{D}_2(\mathfrak{F}) \), the set of density operators \( \rho \) on \( \mathfrak{F} \) such that trace(\( \rho^{1/2} H \rho^{1/2} \)) < \( \infty \), the quantum analogue of the Monge-Kantorovich-Wasserstein distance \( \text{dist}^{\text{MK,2}} \) is defined by the quantum Kantorovich problem (see Definition 2.2 in [11])

\[
MK_h(R, S) := \inf_{F \in \mathcal{C}(R, S)} \text{trace}_{\mathfrak{F} \otimes \mathfrak{F}}(F^{1/2}CF^{1/2}),
\]

where \( \mathcal{C}(R, S) \) is the set of quantum couplings of \( R \) and \( S \), i.e.

\[
\mathcal{C}(R, S) := \{ F \in \mathcal{D}(\mathfrak{F} \otimes \mathfrak{F}) \text{ s.t. } \text{trace}_{\mathfrak{F} \otimes \mathfrak{F}}((A \otimes I + I \otimes B)F) = \text{trace}_{\mathfrak{F}}(AR + BS) \}.
\]

(See Definition 2.1 in [11].) The functional \( MK_h \) is a particularly convenient tool to obtain a convergence rate for the mean-field limit in quantum mechanics that is uniform in the Planck constant \( \hbar \) (see Theorem 2.4 in [11], and Theorem 3.1 in [14] for precise statements of these results).

The striking analogy between the Wasserstein distance \( \text{dist}^{\text{MK,2}} \) and the quantum functional \( MK_h \) suggests the following questions concerning a possible Brenier
type theorem in quantum mechanics, motivated in a heuristic way by the following considerations.

As mentioned before the classical underlying paradigm for quantum mechanics is the classical phase space $\mathbb{R}^{2d} = T^* \mathbb{R}^d$ equipped with the standard symplectic structure leading to the Poisson bracket defined in item (e) above. Therefore, in this setting and under assumption (2), equation (3) reads

\[(9) \quad (z' - \nabla a(z))\pi(dz, dz') = 0,\]

where $z := (q, p)$ and $z' := (q', p')$ are the coordinates on the phase space $T^* \mathbb{R}^d$ and $dz := dq dp$, $dz' := dq' dp'$.

Defining the mapping $J : T^* \mathbb{R}^d \rightarrow T^* \mathbb{R}^d$ entering the definition of the symplectic form $\sigma$ of $T^* \mathbb{R}^d$ as $\sigma(dz, dz') = dz \wedge dJz'$ — in the $z = (q, p)$ coordinates

\[J = \begin{pmatrix} 0 & I_{\mathbb{R}^d} \\ -I_{\mathbb{R}^d} & 0 \end{pmatrix},\]

— equation (9) can be put in the form

\[(10) \quad (z' - \{Jz, a(z)\})\pi(dz, dz') = 0.\]

This symplectic formulation of the Brenier theorem is more likely to have an analogue in quantum mechanics. Indeed, according to the items (c), (d) and (e) above, the factor $(z' - \{Jz, a(z)\})$ should be put in correspondence with the (vector-valued) operator on $\mathcal{H} \otimes \mathcal{H}$

\[(11) \quad I_\mathcal{H} \otimes Z - \frac{1}{i\hbar}[JZ, A] \otimes I_\mathcal{H} =: I_\mathcal{H} \otimes Z - \nabla^Q A \otimes I_\mathcal{H},\]

for some operator $A$ on $\mathcal{H}$. In (11), $Z$ designates the vector of operator-valued coordinates $(Q_1, \ldots, Q_d, P_1, \ldots, P_d)$.

Having in mind that the optimal classical coupling $\pi$ should be put in correspondence with an optimal element $F_{op}$ of $\mathcal{C}(R, S)$ defined in (8), the only ambiguity which remains in giving a quantum version of (10) is the choice of an ordering for the product of the operators $I_\mathcal{H} \otimes Z - \nabla^Q A \otimes I_\mathcal{H}$ and $F_{op}$.

It happens that this ambiguity will be resolved by distributing the square-root of $F_{op}$ on both sides of the expression (11), which leads us to the very symmetric equality (see Theorem 2.6 in the next section):

\[(12) \quad F_{op}^{1/2}(I_\mathcal{H} \otimes Z - \nabla^Q A \otimes I_\mathcal{H})F_{op}^{1/2} = 0.\]

(Notice that one cannot define a square-root of the optimal coupling in the classical case, since such a coupling is a Dirac measure, as shown by (1).)

Clearly (12) gives a hint on the structure of optimal quantum couplings in the definition (7) of the $MK^h(R, S)$ and on an analogue of the notion of Brenier optimal transport map. Notice that we are missing a quantum analogue of the original variational problem considered by Monge, or, equivalently, of the coupling (1), so that defining a notion of quantum optimal transport seems far from obvious.

Nevertheless, (12) says that, once projected on the orthogonal of the kernel of an optimal coupling, the operators $I_\mathcal{H} \otimes Z$ and $\nabla^Q A \otimes I_\mathcal{H}$ are equal, in agreement with Brenier’s theorem put in the form: “the support of the optimal coupling is the graph of a convex function”.

The presence of $F_{op}^{1/2}$ on both sides of the expression between parenthesis in the left hand side of (12) forbids getting a quantum equivalent to (4), whose formulation is not clear anyway. Indeed, changes of variables in quantum mechanics are ill
defined, except for linear symplectic mappings through the metaplectic representation.

However, denoting by \( Z' \) the (operator-valued) vector

\[
Z' := \nabla^Q A,
\]

and writing the trace of the left hand side of (12) in terms of the marginals of \( F_{op} \) shows that

\[
\text{(13)} \quad \text{trace} (Z R) = \text{trace} \left( Z' S \right).
\]

Formula (13) can be interpreted in the framework of the so-called Ehrenfest correspondence principle (abusively called Ehrenfest’s Theorem sometimes) [10, 15]: in quantum mechanics, trace \( (Z R) \) is known as the expected value of the variable \( Z \) in the state \( R \) (in the case where \( R = |\varphi\rangle\langle\varphi| \), then trace \( (Z R) = (\varphi \cdot Z \varphi)_R \)). It is the only deterministic quantity that one can associate to a particle in a given state, by taking the average of the (non-deterministic) result of (an — in principle — infinite number of) measurements. It is interpreted in the (statistical) Ehrenfest picture as the classical value of the coordinate \( Z \) of the state \( R \). Thus the Ehrenfest interpretation of (13) is clear: the deterministic information we have on the state \( R \) is transported to the corresponding one on the state \( S \) by the change of variables \( Z \mapsto Z' \).

To conclude this introduction, we mention other attempts at defining analogues of the Wasserstein, or Monge-Kantorovich distances in the quantum setting. For instance Życzkowski and Słomczyński [25] (see also section 7.7 in chapter 7 of [3]) proposed to consider the original Monge distance (also called the Kantorovich-Rubinstein distance, or the Wasserstein distance of exponent 1) between the Husimi transforms of the density operator.

Besides the quantity \( MK_h \) appeared in [11], other analogues of the Wasserstein distance of exponent 2 for quantum densities have been proposed by several other authors. For instance Carlen and Maas have defined a quantum analogue of the Benamou-Brenier formula (see [2] or Theorem 8.1 in chapter 8 of [24]) for the classical Wasserstein distance of exponent 2, and their idea has been used to obtain a quantum equivalent of the so-called HWI inequality: see [8, 9, 21].

Other propositions for generalizing Wasserstein distances to the quantum setting have emerged more recently, such as [16] (mainly focussed on pure states) or [20], very close to our definition of \( MK_h \), except that the set of couplings used in the minimization is different and based instead on the notion of “quantum channels”.

2. Main Results

The key argument in deriving the structure (1) of optimal couplings for the Kantorovich problem involves a min-max type result known as “Kantorovich duality”. For each \( \mu, \nu \in \mathcal{P}_2(\mathbb{R}^d) \), one has

\[
\text{dist}_{MK,2}(\mu, \nu) = \sup_{\phi, \psi \in C_c(\mathbb{R}^d)} \left( \int_{\mathbb{R}^d} \phi(x) \mu(dx) + \int_{\mathbb{R}^d} \psi(y) \nu(dy) \right).
\]
When $\mu, \nu$ do not charge small sets, in the sense that they satisfy (2), one can prove that the supremum in the r.h.s. of (14) is actually attained and

$$\text{dist}_{MK,2}(\mu, \nu) = \min_{\pi \in \Pi(\mu, \nu)} \int_{\mathbb{R}^d \times \mathbb{R}^d} |x - y|^2 \pi(dx, dy)$$

$$= \int_{\mathbb{R}^d \times \mathbb{R}^d} |x - y|^2 \pi_{op}(dx, dy)$$

$$= \max_{\phi \in L^1(\mu), \psi \in L^1(\nu)} \left( \int_{\mathbb{R}^d} \phi(x) \mu(dx) + \int_{\mathbb{R}^d} \psi(y) \nu(dy) \right)$$

$$= \int_{\mathbb{R}^d} \phi_{op}(x) \mu(dx) + \int_{\mathbb{R}^d} \psi_{op}(y) \nu(dy)$$

for two proper convex l.s.c. functions $\phi_{op}$ and $\psi_{op}$ on $\mathbb{R}^d$.

Moreover, $a(x) := \frac{1}{2}(x^2 - \phi_{op}(x))$ is precisely the function appearing in (3), the gradient of which defines a.e. the Brenier optimal transport map of the previous section. (See Theorem 1.3, Proposition 2.1 and Theorem 2.9 in [23].)

Likewise, the operator $A$ in (12) will be similarly related to an optimal operator appearing in a dual formulation of definition (7), to be presented below.

Before we state the quantum analogue of the Kantorovich duality, we need some technical preliminaries.

The quantum transport cost is the operator

$$C := \sum_{j=1}^d \left( (x_j - y_j) - h^2 (\partial_{x_j} - \partial_{y_j})^2 \right),$$

viewed as an unbounded self-adjoint operator on $L^2(\mathbb{R}^d \times \mathbb{R}^d)$ with domain

$$\text{Dom}(C) := \{ \psi \in L^2(\mathbb{R}^d \times \mathbb{R}^d) \text{ s.t. } |x - y|^2 \psi \text{ and } |D_x - D_y|^2 \psi \in L^2(\mathbb{R}^d \times \mathbb{R}^d) \}.\tag{15}$$

Henceforth we denote by $H$ the Hamiltonian of the quantum harmonic oscillator, i.e.

$$H := |x|^2 - h^2 \Delta_x,$$

which is a self-adjoint operator on $L^2(\mathbb{R}^d)$ with domain

$$\text{Dom}(H) := \{ \phi \in H^2(\mathbb{R}^d) \text{ s.t. } |x|^2 \phi \in L^2(\mathbb{R}^d) \}.\tag{16}$$

In the sequel, we shall also need the form-domains of the operators $H$ and $C$:

$$\text{Form-Dom}(H) := \{ \phi \in H^1(\mathbb{R}^d) \text{ s.t. } |x| \phi \in L^2(\mathbb{R}^d) \},$$

$$\text{Form-Dom}(C) := \{ \psi \in \mathcal{F} \otimes \mathcal{H} \text{ s.t. } (x_j - y_j) \psi \text{ and } (\partial_{x_j} - \partial_{y_j}) \psi \in \mathcal{F} \otimes \mathcal{H}, 1 \leq j \leq d \}.\tag{17}$$

---

3If $u \in C^\infty_c(\mathbb{R}^d)$, one has

$$\int_{\mathbb{R}^d} |x|^2 u(x) Hu(x) dx = \int_{\mathbb{R}^d} (|x|^4 u(x)^2 + h^2 |x|^2 \nabla u(x)^2) dx + h^2 \int_{\mathbb{R}^d} x \cdot \nabla (u^2) dx$$

$$= \int_{\mathbb{R}^d} (|x|^4 - 2h^3) u(x)^2 + h^2 |x|^2 \nabla u(x)^2) dx,$$

so that $||x|^2 u||_{L^2(\mathbb{R}^d)}^2 \leq ||Hu||_{L^2(\mathbb{R}^d)} ||x|^2 u||_{L^2(\mathbb{R}^d)} + dh^2 |u||_{L^2(\mathbb{R}^d)}$. Thus, if $u \in L^2(\mathbb{R}^d)$ and $Hu \in L^2(\mathbb{R}^d)$, then one has $|x|^2 u \in L^2(\mathbb{R}^d)$, which implies in turn that $-\Delta u \in L^2(\mathbb{R}^d)$. The same argument shows that $U \in L^2(\mathbb{R}^d \times \mathbb{R}^d)$ and $CU \in L^2(\mathbb{R}^d \times \mathbb{R}^d)$ imply that $|x - y|^2 U \in L^2(\mathbb{R}^d \times \mathbb{R}^d)$. These observations imply that the domains of $H$ and $C$ are the spaces given above.
The definition of the form-domain of a self-adjoint operator can be found for instance in section VIII.6, Example 2 of [18]. Observe that

\[
\text{Form-Dom}(H \otimes I + I \otimes H) = \{ \psi \in H^1(\mathbb{R}^d \times \mathbb{R}^d) : (|x| + |y|)\psi \in L^2(\mathbb{R}^d \times \mathbb{R}^d) \} = \text{Form-Dom}(C).
\]

Lemma 2.1. Let \( R, S \in \mathcal{D}_2(\mathfrak{g}) \), and let \( Q \in \mathcal{C}(R, S) \). Each eigenfunction \( \Phi \) of \( Q \) such that \( Q\Phi \neq 0 \) belongs to \( \text{Form-Dom}(H \otimes I + I \otimes H) \) and

\[
0 \leq \langle \Phi | H \otimes I + I \otimes H | \Phi \rangle \leq \text{trace}_\mathfrak{g}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2}) < \infty.
\]

In particular, \( \Phi \in \text{Dom}(C) \) with

\[
\langle \Phi | C | \Phi \rangle \leq 2 \text{trace}_\mathfrak{g}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2}) < \infty.
\]

Proof. Since \( R, S \in \mathcal{D}_2(\mathfrak{g}) \), one has

\[
\text{trace}_\mathfrak{g}(Q^{1/2}(H \otimes I)Q^{1/2}) = \text{trace}_\mathfrak{g}(R^{1/2}HR^{1/2}) < \infty
\]

and

\[
\text{trace}_\mathfrak{g}(Q^{1/2}(I \otimes H)Q^{1/2}) = \text{trace}_\mathfrak{g}(S^{1/2}HS^{1/2}) < \infty
\]

for each \( Q \in \mathcal{C}(R, S) \) by Lemma C.3. In particular

\[
\text{trace}_\mathfrak{g}(Q^{1/2}(H \otimes I + I \otimes H)Q^{1/2}) < \infty.
\]

Let \( (\Phi_k)_{k \geq 0} \) be a complete orthonormal system of eigenvectors of \( Q \), and let \( (\lambda_k)_{k \geq 0} \) be the sequence of eigenvalues of \( Q \) such that \( Q\Phi_k = \lambda_k\Phi_k \) for each \( k \geq 0 \). Thus

\[
\lambda_k > 0 \implies \Phi_k \in \text{Form-Dom}(H \otimes I + I \otimes H)
\]

and

\[
\sum_{k \geq 0} \lambda_k \langle \Phi_k | H \otimes I + I \otimes H | \Phi_k \rangle = \text{trace}_\mathfrak{g}(Q^{1/2}(H \otimes I + I \otimes H)Q^{1/2})
\]

\[
= \text{trace}_\mathfrak{g}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2}) < \infty,
\]

and this implies the desired inequality. Using (19) shows that

\[
\Psi \in \text{Form-Dom}(H \otimes I + I \otimes H) \implies \Psi \in \text{Form-Dom}(C)
\]

\[
0 \leq \langle \Psi | C | \Psi \rangle \leq \langle \Psi | H \otimes I + I \otimes H | \Psi \rangle.
\]

\[\square\]

2.1. A Quantum Analogue to the Kantorovich Duality. The statement below is an analogue of the Kantorovich Duality Theorem (Theorem 1.3 in [23], or Theorem 6.1.1 in [1]) for the quantum transport cost operator \( C \) defined by (15).

Theorem 2.2 (Quantum duality). Let \( R, S \in \mathcal{D}_2(\mathfrak{g}) \). Then

\[
\min_{F \in \mathcal{C}(R,S)} \text{trace}_\mathfrak{g}(F^{1/2}CF^{1/2}) = \sup_{(A,B) \in \mathfrak{R}} \text{trace}_\mathfrak{g}(RA + SB),
\]

where

\[
\mathfrak{R} := \{(A,B) \in \mathcal{L}(\mathfrak{g}) \times \mathcal{L}(\mathfrak{g}) : A = A^*, B = B^* \text{ and } A \otimes I + I \otimes B \leq C\}.
\]

In the definition of \( \mathfrak{R} \), the inequality

\[
A \otimes I + I \otimes B \leq C
\]

means that

\[
\langle \psi | A \otimes I + I \otimes B | \psi \rangle \leq \langle \psi | C | \psi \rangle
\]

for all \( \psi \in \text{Form-Dom}(C) \).
Notice that the inf on the left hand side of the duality formula is attained — in other words, there always exists an optimal coupling \( F \in \mathcal{C}(R, S) \). On the contrary, the sup in the right hand side of the duality formula is in general not attained — at least not attained in the class \( \mathfrak{H} \) in general.

2.2. **Existence of Optimal Operators** \( A, B \). In this section, we explain how the sup in the right hand side of the duality formula is attained in a class of operators \( (A, B) \) larger than \( \mathfrak{H} \).

2.2.1. **Gelfand triple associated to a nonnegative trace-class operator.** We shall use repeatedly the following construction. Given a separable Hilbert space \( \mathcal{H} \) and \( T \in L^1(\mathcal{H}) \) such that \( T = T^* \geq 0 \), let \( (\xi_n)_{n \geq 1} \) be a complete orthonormal basis of \( \mathcal{H} \) of eigenvectors of \( T \). Set

\[
J_0[T] := \text{span}\{\xi_n \text{ s.t. } \langle \xi_n | T \xi_n \rangle > 0\},
\]

and

\[
(\phi|\psi)_T := \langle \phi | T^{-1} | \psi \rangle, \quad \phi, \psi \in J_0[T].
\]

Let \( J[T] \) designate the completion of \( J_0[T] \) for the inner product \( \langle \cdot | \cdot \rangle_T \). Obviously

\[
J[T] \subset J_0[T] = \text{Ker}(T)^\perp \subset J[T]',
\]

(where \( J_0[T] \) is the closure of \( J_0[T] \) in \( \mathfrak{H} \)). The first inclusion is continuous since, for each \( \phi \in J_0[T] \), one has

\[
\|\phi\|_{\mathfrak{A}}^2 \leq \|T\| \langle \phi | T^{-1} | \phi \rangle = \|T\| \langle \phi | T^{-1} | \phi \rangle.
\]

The operator \( T^{-1/2} \), which is a priori defined on \( J_0[T] \) only, has a unique continuous extension which is the unitary transformation

\[
T^{-1/2} : J[T] \rightarrow \text{Ker}(T)^\perp \quad \text{with adjoint} \quad T^{-1/2} : \text{Ker}(T)^\perp \rightarrow J[T]'.
\]

In other words, one has a Gelfand triple

\[
J[T] \subset \text{Ker}(T)^\perp \subset J[T]'.
\]

(Notice that the embedding \( J[T] \subset \text{Ker}(T)^\perp \) is compact since \( T^{1/2} \) is a Hilbert-Schmidt, and therefore compact, operator on \( \mathfrak{H} \).) With the unitary transformation (25), one defines the isometric isomorphism

\[
L(J[T], J[T]') \cong \mathfrak{H} \ni \Phi \mapsto T^{1/2} \Phi T^{1/2} = Z \in L(\text{Ker}(T)^\perp).
\]

Under this isomorphism, \( Z^* \) is obviously mapped to \( Z^* \).

2.2.2. **The optimality class** \( \hat{\mathfrak{H}}(R, S) \). While the original class \( \mathfrak{H} \) is independent of the quantum density operators \( R \) and \( S \), the optimality class \( \hat{\mathfrak{H}}(R, S) \) significantly depends on \( R, S \).

**Definition 2.3.** For each \( R, S \in D_2(\mathfrak{H}) \), let \( \hat{\mathfrak{H}}(R, S) \) be the set of \( (v, w) \) with \( v \in L(J[R], J[R]') \) and \( w \in L(J[S], J[S]') \) such that

(a) the operators \( V = R^{1/2} v R^{1/2} \) and \( W = S^{1/2} w S^{1/2} \) satisfy

\[
2R^{1/2} H R^{1/2} \geq V = V^* \in L^1(\text{Ker}(R)^\perp)
\]

\[
2R^{1/2} H R^{1/2} \geq W = W^* \in L^1(\text{Ker}(S)^\perp);
\]

(b) for each \( \Phi \in J_0[R] \otimes J_0[S] \), one has

\[
\langle \Phi | v \otimes I + I \otimes w | \Phi \rangle \leq \langle \Phi | C | \Phi \rangle.
\]
Notice that the left hand side of the inequality in condition (b) is well defined, since $\mathcal{J}_0[R] \subset \mathcal{J}[R]$, so that $\nu \mathcal{J}_0[R] \subset \mathcal{J}[R]'$. Hence any element of $\nu \mathcal{J}_0[R]$ is a linear functional which can be evaluated on any element of $\mathcal{J}_0[R] \subset \mathcal{J}[R]$, and likewise any element of $\nu \mathcal{J}_0[S]$ is a linear functional which can be evaluated on any element of $\mathcal{J}_0[S] \subset \mathcal{J}[S]$.

As for the right hand side, let $(e_j)_{j \geq 1}$ and $(f_k)_{k \geq 1}$ be complete orthonormal systems of eigenvectors of $R$ and $S$ respectively in $\mathcal{H}$. By the implication in (57) (see Lemma C.1 in the Appendix)

$$e_j \in \text{Ker}(R)^\perp \implies e_j \in \text{Form-Dom}(H),$$
$$f_k \in \text{Ker}(S)^\perp \implies f_k \in \text{Form-Dom}(H).$$

In particular

$$\mathcal{J}_0[R] \otimes \mathcal{J}_0[S] \subset \text{Form-Dom}(H \otimes I + I \otimes H) \subset \text{Form-Dom}(C)$$

so that the right hand side of the inequality in (b) is finite.

2.2.3. The sup is attained in $\mathcal{K}(R,S)$. Passing from $\mathcal{K}$ to $\mathcal{K}(R,S)$ is equivalent to seeking the optimal Kantorovich potential in $L^1(\mathbb{R}^d,\mu)$ as in Theorems 1.3 or Theorem 2.9 of [23], instead of $C_b(\mathbb{R}^d)$ — see the last sentence in Theorem 1.3 of [23], together with Remark 1.6 in that same reference.

**Theorem 2.4** (Existence of optimal duality potentials). For all $R,S \in \mathcal{D}_2(\mathcal{H})$,

$$\min_{F \in \mathcal{C}(R,S)} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}CF^{1/2}) = \max_{(a,b) \in \mathcal{K}(R,S)} \text{trace}_{\mathcal{H}}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}).$$

2.3. **Structure of optimal couplings.** In the classical setting, pick a proper convex l.s.c. function $\phi : \mathbb{R}^d \to \mathbb{R} \cup \{+\infty\}$, and let $\mu \in \mathcal{P}(\mathbb{R}^d)$ satisfy condition (2) and

$$(28) \quad \int_{\mathbb{R}^d} (|x|^2 + |\nabla \phi(x)|^2 + |\phi(x)| + |\phi^*(\nabla \phi(x))|) \mu(dx) < \infty.$$

Then

$$(29) \quad \pi(dx,dy) := \mu(dx)\delta(y - \nabla \phi(x))$$

is an optimal coupling of the measures $\mu$ and $\nu := \nabla \phi^\# \mu$ for the Kantorovich problem with the cost $C(x, y) = ||x - y||^2$.

We begin with a sufficient condition on couplings for optimality. This is the analogue of the sufficient condition in Theorem 6.1.4 of [1].

**Theorem 2.5** (Sufficient condition for optimality). Let $(A,B) \in \mathcal{K}$ be such that $\text{Ker}(C - A \otimes I - I \otimes B) \neq \{0\}$. Let $(\Phi_j)$ be a complete orthonormal system in $\text{Ker}(C - A \otimes I - I \otimes B)$, and let

$$F := \sum_j \lambda_j |\Phi_j\rangle \langle \Phi_j|, \quad \text{with} \quad \lambda_j \geq 0 \quad \text{and} \quad \sum_j \lambda_j = 1.$$

Call $F_1 := \text{trace}_A(F)$ and $F_2 := \text{trace}_B(F)$ the partial traces of $F$ on the second and first factor in $\mathcal{H} \otimes \mathcal{H}$ respectively. Then $F$ is an optimal coupling of $F_1$ and $F_2$:

$$\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}CF^{1/2}) = \min_{Q \in \mathcal{C}(F_1,F_2)} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q^{1/2}CQ^{1/2})$$
$$= \sup_{(a,b) \in \mathcal{K}} \text{trace}_{\mathcal{H}}(F_1a + F_2b) = \text{trace}_{\mathcal{H}}(F_1A + F_2B).$$
In the classical setting, the structure (29) of optimal couplings is a straightforward consequence of (28). Indeed, the set of points where the Young inequality
\[ \phi(x) + \phi^*(y) \geq x \cdot y \]
becomes an equality is included in \( \text{graph}(\partial \phi) \). This suggests the idea of looking for a quantum analogue of the Brenier optimal transport map in the optimality criterion in Theorem 2.5.

We shall give a necessary condition for optimality with \((A, B) \in \mathcal{F}\). Henceforth we use the following notation:

\[ q_j \psi(x_1, \ldots, x_d) := x_j \psi(x_1, \ldots, x_N), \quad p_j \psi(x_1, \ldots, x_d) := -ih \partial_{x_j} \psi(x_1, \ldots, x_d) \]

for all \( \psi \in \text{Form-Dom}(H) \) and all \( j = 1, \ldots, d \), and

\[ q_j S := \frac{h}{i}[p_j, S], \quad p_j S := -\frac{h}{i}[q_j, S]. \]

We shall also need the following elementary functional analytic considerations. The linear space \( \text{Dom}(C) \) endowed with the inner product

\[ \langle \Phi, \Psi \rangle_{\text{Dom}(C)} = \langle \Phi|\Psi \rangle_{\mathcal{H} \otimes \mathcal{H}} + \langle C\Phi|C\Psi \rangle_{\mathcal{H} \otimes \mathcal{H}} \]

is a Hilbert space. Hence \( C \in \mathcal{L}(\text{Dom}(C), \mathcal{H} \otimes \mathcal{H}) \) (with norm at most 1). Since \( C \) is symmetric on \( \text{Dom}(C) \), it has a unique extension as an element of \( \mathcal{L}(\mathcal{H}, \text{Dom}(C)' \mathcal{H}) \) (where \( \text{Dom}(C)' \) designates the topological dual of \( \text{Dom}(C) \)), which is defined by the formula

\[ (C\Phi, \Psi)_{\text{Dom}(C)'} = \langle \Phi|C\Psi \rangle_{\mathcal{H} \otimes \mathcal{H}} \]

for all \( \Phi \in \mathcal{H} \otimes \mathcal{H} \) and \( \Psi \in \text{Dom}(C) \).

On the other hand, the linear space \( \text{Form-Dom}(H \otimes I + I \otimes H) \) endowed with the inner product

\[ \langle \Phi, \Psi \rangle_{\text{Form-Dom}(H \otimes I + I \otimes H)} = \langle \Phi|\Psi \rangle_{\mathcal{H} \otimes \mathcal{H}} + \langle \Phi|H \otimes I + I \otimes H|\Psi \rangle \]

is a Hilbert space. If \( T \in \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \mathcal{H} \otimes \mathcal{H}) \) is a symmetric operator, it has a unique extension as an element of \( \mathcal{L}(\mathcal{H}, \text{Form-Dom}(H \otimes I + I \otimes H)') \). This extension is defined by the formula

\[ (T\Phi, \Psi)_{\text{Form-Dom}(H \otimes I + I \otimes H)'} = \langle \Phi|T\Psi \rangle_{\mathcal{H} \otimes \mathcal{H}} \]

(where \( \text{Form-Dom}(H \otimes I + I \otimes H)' \) is the topological dual of \( \text{Form-Dom}(H \otimes I + I \otimes H) \)) for all \( \Phi \in \mathcal{H} \otimes \mathcal{H} \) and \( \Psi \in \text{Form-Dom}(H \otimes I + I \otimes H) \).

In particular

\[ [T, C] : \text{Dom}(C) \cap \text{Form-Dom}(H \otimes I + I \otimes H) \to \text{Dom}(C)' \cap \text{Form-Dom}(H \otimes I + I \otimes H)' \]

is a continuous linear map. Since

\[ \text{Dom}(C)' + \text{Form-Dom}(H \otimes I + I \otimes H)' \subset (\text{Dom}(C) \cap \text{Form-Dom}(H \otimes I + I \otimes H))' \],

the bilinear functional

\[ \langle \Phi, \Psi \rangle \mapsto \langle T[\Phi[C\Psi]] \rangle_{\mathcal{H} \otimes \mathcal{H}} - \langle C\Phi[T\Psi] \rangle_{\mathcal{H} \otimes \mathcal{H}} \]

is continuous on \( \text{Dom}(C) \cap \text{Form-Dom}(H \otimes I + I \otimes H) \).

**Theorem 2.6.** Let \( R, S \in \mathcal{D}_2(\mathcal{H}) \), let \( F \in \mathcal{C}(R, S) \) be an optimal coupling, i.e.

\[ \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}CF^{1/2}) = \min_{Q \in \mathcal{C}(R, S)} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q^{1/2}CQ^{1/2}). \]
If there exists an optimal pair \((A,B) \in \mathcal{R}\) such that
\[
\text{trace}_\mathcal{F}(RA + SB) = \sup_{(a,b) \in \mathcal{R}} \text{trace}_\mathcal{F}(Ra + Sb),
\]
then
(a) any eigenvector \(\Phi\) of \(F\) such that \(F\Phi \neq 0\) satisfies
\[
\Phi \in \text{Dom}(C) \text{ and } C\Phi = (A \otimes I + I \otimes B)\Phi;
\]
(b) let us denote
\[
A := \frac{1}{2}(H - A) \text{ and } B := \frac{1}{2}(H - B).
\]
Then, for each \(j = 1, \ldots, d,\) one has
\[
F^{1/2}(I \otimes q_j - \mathcal{D}_{q_j}, A \otimes I)F^{1/2} = F^{1/2}(I \otimes p_j - \mathcal{D}_{p_j}, A \otimes I)F^{1/2} = 0,
\]
\[
F^{1/2}(q_j \otimes I - I \otimes \mathcal{D}_{q_j} B)F^{1/2} = F^{1/2}(p_j \otimes I - I \otimes \mathcal{D}_{p_j} B)F^{1/2} = 0.
\]

As mentioned in the introduction, these two last identities are obviously analogous to the condition (9)
\[
(z' - \nabla a(z))\pi(dz, dz') = 0
\]
obtained in the setting of classical optimal transport in the case where the convex function \(a\) is smooth, so that \(\partial a(z) = \{\nabla a(z)\}\) (see the Brenier or the Knott-Smith theorems, stated as Theorem 2.12 (i)-(ii) in [23]. Indeed, using the (vector-valued) operator
\[
\nabla^Q = (\mathcal{D}_{q_1}, \ldots, \mathcal{D}_{q_d}, \mathcal{D}_{p_1}, \ldots, \mathcal{D}_{p_d})
\]
and the vector of operators \(Z\) defined right after (11), statement (b) of Theorem 2.6 reads
\[
F^{1/2}(Z \otimes I - I \otimes \nabla^Q A)F^{1/2} = 0.
\]
Notice that the quantum analogue of the function \(a\) is the operator \(\frac{1}{2}(H - A)\) (equivalently, the classical analogue of \(A\) is \((|q|^2 + |p|^2) - 2\phi(q,p))\) as seen in Remark 2.13 (iii) following Theorem 2.12 in [23], where the relation between \(\phi\) and the optimal pair in the Kantorovich duality theorem is described in detail.

3. Proof of Theorem 2.2

Set \(E := \mathcal{L}(\mathcal{H} \otimes \mathcal{H})\). Define \(f, g : E \to \mathbb{R} \cup \{+\infty\}\) by the formulas
\[
f(T) := \begin{cases} 
0 & \text{if } T = T^* \geq -C, \\
+\infty & \text{otherwise},
\end{cases}
\]
and
\[
g(T) := \begin{cases} 
\text{trace}_\mathcal{F}(RA + SB) & \text{if } T = T^* = A \otimes I + I \otimes B, \\
+\infty & \text{otherwise}.
\end{cases}
\]
For each \(T = T^* \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H})\), the constraint \(T \geq -C\) in the definition of \(f\) is to be understood as follows:
\[
\langle \phi | T | \phi \rangle \geq -\langle \phi | C | \phi \rangle \text{ for each } \phi \in \text{Form-Dom}(C).
\]
On the other hand, the nullspace of the linear map
\[
\Gamma : \mathcal{L}(\mathcal{H}) \times \mathcal{L}(\mathcal{H}) \ni (A,B) \mapsto A \otimes I + I \otimes B \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H})
\]
is \(\text{Ker}(\Gamma) = \{(tI, -tI) \text{ s.t. } t \in \mathbb{C}\}\). Since \(\text{trace}_\mathcal{F}(R) = \text{trace}_\mathcal{F}(S) = 1\), one has
\[
\text{trace}_\mathcal{F}(RA + SB) = t \text{trace}_\mathcal{F}(R - S) = 0 \quad \text{for all } (A,B) = (tI, -tI) \in \text{Ker}(\Gamma).
\]
Therefore, the prescription above defines indeed a unique function $g$ on $E$ with values in $\mathbb{R}$ (in the sense of the definition in §4 of [19] on p. 28) of the convex set

$$\{ T = T^* \in E \text{ s.t. } T \geq -C \},$$

while $g$ is the extension by $+\infty$ of a real-valued linear functional defined on the linear subspace $\text{ran}(\Gamma)$ of $E$. Clearly,

$$f(0) = g(0) = 0.$$ 

Moreover $f$ is continuous at 0. Indeed, the Heisenberg uncertainty inequality implies that $C \geq 2dhI$, so that

$$T = T^* \text{ and } \|T\| < dh \implies T \geq -2dhI \geq -C.$$ 

Hence

$$T = T^* \text{ and } \|T\| < dh \implies f(T) = 0,$$

so that $f$ is continuous at 0.

By the Fenchel-Rockafellar duality theorem (Theorem 1.12 in [5])

$$\inf_{T \in E} (f(T) + g(T)) = \max_{\Lambda \in E'} (-f^*(\Lambda) - g^*(\Lambda)).$$

Let us compute $f^*$ and $g^*$. First

$$f^*(\Lambda) = \sup_{T \in E} \left( -\Lambda, T \right) - f(T) = \sup_{T^* \in E \text{ s.t. } T \geq -C} \left( -\Lambda, T \right).$$

If $\Lambda \in E'$ is not $\geq 0$, there exists $T_0 = T_0^* \geq 0$ such that $\langle \Lambda, T_0 \rangle = -\alpha < 0$. In particular, $nT_0 = nT_0^* \geq -C$ for each $n \geq 0$, so that

$$f^*(\Lambda) \geq \sup_{n \geq 1} \langle -\Lambda, nT_0 \rangle = \sup_{n \geq 1} n\alpha = +\infty.$$ 

For $\Lambda \in E'$ such that $\Lambda \geq 0$, define

$$\langle \Lambda, C \rangle := \sup_{T^* \in E \text{ s.t. } T \geq -C} \langle \Lambda, T \rangle \in [0, +\infty].$$

(That $\langle \Lambda, C \rangle \geq 0$ comes from observing that $T = 0$ satisfies the constraints.) With this definition

$$f^*(\Lambda) = \begin{cases} \langle \Lambda, C \rangle & \text{if } \Lambda \geq 0, \\ +\infty & \text{otherwise.} \end{cases}$$

Next

$$g^*(\Lambda) = \sup_{T \in E} \left( \langle \Lambda, T \rangle - g(T) \right) = \sup_{T^* \in E \text{ s.t. } T = RA + SB \in E} \left( \langle \Lambda, T \rangle - \text{trace}(RA + SB) \right).$$
If there exists $A = A^* \in \mathcal{L}(\mathcal{H})$ and $B = B^* \in \mathcal{L}(\mathcal{H})$ such that
\[
\langle \Lambda, A \otimes I + I \otimes B \rangle > \text{trace}(RA + SB),
\]
then
\[
g^*(\Lambda) \geq \sup_{n \geq 1} \left( n\langle \Lambda, A \otimes I + I \otimes B \rangle - n\text{trace}_B(RA + SB) \right) = +\infty.
\]
Likewise, if
\[
\langle \Lambda, A \otimes I + I \otimes B \rangle < \text{trace}_B(RA + SB),
\]
then
\[
g^*(\Lambda) \geq \sup_{n \geq 1} \left( (\Lambda, -n(A \otimes I + I \otimes B)) - \text{trace}_B(-n(RA + SB)) \right) = +\infty.
\]
Hence
\[
g^*(\Lambda) = \begin{cases} 0 & \text{if } \langle \Lambda, A \otimes I + I \otimes B \rangle = \text{trace}_B(RA + SB), \\ +\infty & \text{otherwise}. \end{cases}
\]
Notice that the prescription $(\Lambda, T) = \text{trace}_B(RA + SB)$ whenever $T = T^* \in \text{ran}(\Lambda)$ defines a unique linear functional on $\text{ran}(\Lambda)$ since $\text{Ker}(\Lambda) = \{0\}$ as explained above.

By the Fenchel-Rockafellar duality theorem recalled above,
\[
\inf_{T \in E} (f(T) + g(T)) = \inf_{A \in A^*} \sup_{B \in B^* \in \mathcal{L}(\mathcal{H})} \text{trace}_B(RA + SB)
\]
\[
= \max_{A \in E'} (-f^*(-A) - g^*(-\Lambda)) = \max_{(\Lambda, A \otimes I + I \otimes B) = \text{trace}_B(RA + SB)} (-\Lambda, C)
\]
or equivalently, after exchanging the signs,
\[
\sup_{(A,B) \in \mathcal{K}} \text{trace}_B(RA + SB) = \min_{(\Lambda, A \otimes I + I \otimes B) = \text{trace}_B(RA + SB)} \langle \Lambda, C \rangle.
\]
(We recall that the constraint $A \otimes I + I \otimes B \leq C$ in the definition of $\mathcal{K}$ is to be understood as explained immediately after the statement of Theorem 2.2.)

One can further restrict the min on the right hand side with the following observations.

**Lemma 3.1.** Let $V = \mathcal{L}(\mathcal{H})$ where $\mathcal{H}$ is a separable Hilbert space. If $\ell \in V'$ satisfies $\ell \geq 0$, then
\[
T = T^* \in V \implies \langle \ell, T \rangle \in \mathbb{R} \quad \text{and} \quad \|\ell\| = \langle \ell, I_{\mathcal{H}} \rangle.
\]

**Proof.** Indeed, for all $T = T^* \in V$, one has $-\|T\| I_{\mathcal{H}} \leq T \leq \|T\| I_{\mathcal{H}}$, so that
\[
-\|T\| I_{\mathcal{H}} \leq T \leq \|T\| I_{\mathcal{H}}, \quad \text{so that} \quad -\|T\| \langle \ell, I_{\mathcal{H}} \rangle \leq \langle \ell, T \rangle \leq \|T\| \langle \ell, I_{\mathcal{H}} \rangle.
\]
In particular, for all $T = T^* \in V$, one has $\langle \ell, T \rangle \in \mathbb{R}$. For all $T \in V$ (not necessarily self-adjoint), write
\[
\Re(T) = \frac{1}{2}(T + T^*) \quad \text{and} \quad \Im(T) := \frac{1}{2i}(T^* - T).
\]
If $\langle \ell, T \rangle \neq 0$, there exists $\alpha \in \mathbb{C}$ s.t. $|\alpha| = 1$ and $\langle \ell, \alpha T \rangle = |\langle \ell, T \rangle|$. These considerations show immediately that $\langle \ell, \Im(\alpha T) \rangle = 0$ so that
\[
|\langle \ell, T \rangle| = \langle \ell, \Re(\alpha T) \rangle \leq \langle \ell, I_{\mathcal{H}} \rangle \Re(\alpha T) \|\Re(\alpha T)\|
\]
\[
\leq \frac{1}{2}(\ell, I_{\mathcal{H}})(\|\alpha T\| + \|(\alpha T)^*\|) = \langle \ell, I_{\mathcal{H}} \rangle \|T\|.
\]
Hence $\|\ell\| \leq \langle \ell, I_{\mathcal{H}} \rangle$, while it is obvious that $\langle \ell, I_{\mathcal{H}} \rangle \leq \|\ell\|$. This concludes the proof of Lemma 3.1. \qed
Lemma 3.2. Let 0 ≤ Λ ∈ E’. Then there exists Q ∈ L¹(ℋ ⊗ ℋ) such that

\[ Q = Q^* ≥ 0, \quad \text{and} \quad \|Q\|_{\mathcal{L}^1} ≤ \|\Lambda\|, \]

and L ∈ E’ such that

\[ L ≥ 0, \quad L|_{\mathcal{K}(\mathcal{H} \otimes \mathcal{H})} = 0, \quad \text{and} \quad \|L\| ≤ \|\Lambda\|, \]

satisfying

\[ \Lambda = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q \bullet) + L. \]

Proof. Since \( L¹(\mathcal{H} \otimes \mathcal{H}) = \mathcal{K}(\mathcal{H} \otimes \mathcal{H})' \),

one has

\[ \Lambda|_{\mathcal{K}(\mathcal{H} \otimes \mathcal{H})} = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q \bullet), \]

for some \( Q ∈ L¹(\mathcal{H} \otimes \mathcal{H}) \).

First, observe that

\[ \Lambda ≥ 0 \implies Q = Q^* ≥ 0. \]

Indeed, since \( Q ∈ L¹(\mathcal{H} \otimes \mathcal{H}) \), then \( Q \) is compact. Writing

\[ \Re(Q) = \frac{1}{2}(Q + Q^*) \quad \text{and} \quad \Im(Q) = \frac{i}{2}(Q - Q^*), \]

one has \( \Re(Q) = \Re(Q)^* \) and \( \Im(Q) = \Im(Q)^* \), so that

\[ \langle \Lambda, \Im(Q) \rangle = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(\Re(Q)\Im(Q)) + i\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(\Im(Q)^2) ∈ \mathbb{R}. \]

Since

\[ \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(\Re(Q)\Im(Q)) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(\Im(Q)\Re(Q)) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}((\Re(Q)\Im(Q))^*) = \overline{\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(\Re(Q)\Im(Q))} ∈ \mathbb{R}, \]

one concludes that

\[ \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(\Im(Q)^2) = 0, \quad \text{so that} \quad \Im(Q)^2 = 0. \]

Thus \( Q = Q^* \). Next observe that, for each \( \xi \in \mathcal{H} \otimes \mathcal{H} \),

\[ \langle \xi, \xi \rangle = (\langle \xi, \xi \rangle)^* ≥ 0 \quad \text{so that} \quad \langle \Lambda, \langle \xi, \xi \rangle \rangle = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q \langle \xi, \xi \rangle) = \langle \xi, \xi \rangle ≥ 0. \]

Let \( (\phi_n)_{n ≥ 0} \) be a complete orthonormal sequence of eigenvectors of \( Q \) in \( \mathcal{H} \otimes \mathcal{H} \), and let \( \lambda_n \) be the eigenvalue of \( Q \) associated to \( \phi_n \). Then

\[ \|Q\|_{\mathcal{L}^1} = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q) = \sup_{n ≥ 1} \sum_{k=1}^{n} \lambda_k = \sup_{n ≥ 1} \left( \Lambda - \sum_{k=1}^{n} \langle \phi_n, \phi_n \rangle \right) ≤ \langle \Lambda, I_{\mathcal{H} \otimes \mathcal{H}} \rangle = \|\Lambda\|. \]

Define

\[ L := \Lambda - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q \bullet), \]

so that

\[ L|_{\mathcal{K}(\mathcal{H} \otimes \mathcal{H})} = 0 \]

by construction. Let \( \Pi_n \) be the orthogonal projection on \( \text{span}(\phi_0, \ldots, \phi_n) \). Obviously \( \Pi_n Q = Q \Pi_n \). Then, for each \( T = T^* ≥ 0 \) in \( E \),

\[ 0 ≤ \langle \Lambda, (\Pi_n^* - \Pi_n)T(\Pi_n^* - \Pi_n) \rangle = \langle \Lambda, T \rangle - \langle \Lambda, \Pi_n T \rangle + \langle \Lambda, \Pi_n^* T \rangle + \langle \Lambda, (\Pi_n - \Pi_n^*)T \rangle \]

\[ = \langle \Lambda, T \rangle - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q(T \Pi_n + \Pi_n T - \Pi_n T \Pi_n)) = \langle \Lambda, T \rangle - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}((\Pi_n Q \Pi_n T) - \Pi_n T \Pi_n) \]

\[ \rightarrow \langle \Lambda, T \rangle - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QT) = \langle L, T \rangle \]

as \( n → \infty \), since \( Q ∈ L¹(\mathcal{H} \otimes \mathcal{H}) \), so that \( \Pi_n Q \Pi_n → Q \) in \( L¹(\mathcal{H} \otimes \mathcal{H}) \) as \( n → \infty \). This shows that \( L ≥ 0 \). In particular (see footnote above), one has

\[ \|L\| = \langle L, I_{\mathcal{H} \otimes \mathcal{H}} \rangle = \langle \Lambda, I_{\mathcal{H} \otimes \mathcal{H}} \rangle - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q) ≤ \langle \Lambda, I_{\mathcal{H} \otimes \mathcal{H}} \rangle = \|\Lambda\|. \]
This concludes the proof of Lemma 3.2. \[\square\]

**Lemma 3.3.** Let \(0 \leq \Lambda \in E'\) satisfy\(\langle \Lambda, A \otimes I + B \otimes I \rangle = \text{tr}_{\mathcal{H}}(R A + S B)\), for all \(A = A^*\) and \(B = B^* \in \mathcal{L}(\mathfrak{H})\). Then \(\Lambda\) is of the form\(\Lambda = \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q\bullet),\) with \(Q = Q^* \geq 0\) and \(\text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q) = 1\).

In particular, \(Q\) is a coupling of \(R\) and \(S\).

**Proof.** Let \((e_1, e_2, \ldots)\) be a complete orthonormal system in \(\mathfrak{H}\), and let \(P_n\) be the orthogonal projection on \(\text{span}(e_1, \ldots, e_n)\). Consider\(T_n = (I_{\mathfrak{H}} - P_n) \otimes P_n + P_n \otimes (I_{\mathfrak{H}} - P_n) \geq 0, \quad n \geq 1.\)

Since \(P_n \otimes P_n \geq 0\), one has
\[0 \leq T_n \leq I_{\mathfrak{H}} \otimes P_n + P_n \otimes I_{\mathfrak{H}} \leq I_{\mathfrak{H} \otimes \mathfrak{H}}.\]

Hence
\[0 \leq \langle \Lambda, T_n \rangle \leq \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q(I_{\mathfrak{H}} - P_n) \otimes I_{\mathfrak{H}} + I_{\mathfrak{H}} \otimes (I_{\mathfrak{H}} - P_n))) + \langle L, T_n \rangle \leq \text{tr}_{\mathcal{H}}((Q_1 + Q_2)(I_{\mathfrak{H}} - P_n))) + \langle L, I_{\mathfrak{H} \otimes \mathfrak{H}} \rangle \to \langle L, I_{\mathfrak{H} \otimes \mathfrak{H}} \rangle = \langle \Lambda, I_{\mathfrak{H} \otimes \mathfrak{H}} \rangle - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q)\]

as \(n \to +\infty\). In the formula above, \(Q_1, Q_2\) are the partial traces of \(Q\), defined as follows:
\[Q_1 \in \mathcal{L}^1(\mathfrak{H})\text{ and }\text{tr}_{\mathcal{H}}(Q_1 A) = \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q(A \otimes I_{\mathfrak{H}})),\]
\[Q_2 \in \mathcal{L}^1(\mathfrak{H})\text{ and }\text{tr}_{\mathcal{H}}(Q_2 A) = \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q(I_{\mathfrak{H}} \otimes A)),\]

for each \(A \in \mathcal{L}(\mathfrak{H})\).

Thus
\[\overline{\lim}_{n \to \infty} \langle \Lambda, T_n \rangle \leq \langle \Lambda, I_{\mathfrak{H} \otimes \mathfrak{H}} \rangle - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q) = 1 - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q).\]

Taking \(A = I\) and \(B = 0\) shows indeed that \(\langle \Lambda, I_{\mathfrak{H} \otimes \mathfrak{H}} \rangle = \text{tr}_{\mathcal{H}}(R) = 1.\)

On the other hand, \((I - P_n) \otimes (I - P_n) \geq 0,\) so that
\[T_n = I_{\mathfrak{H}} \otimes P_n + P_n \otimes I_{\mathfrak{H}} - 2P_n \otimes P_n,\]

and hence
\[\langle \Lambda, T_n \rangle = \text{tr}_{\mathcal{H}}((R + S)P_n) - 2\langle \Lambda, P_n \otimes P_n \rangle = \text{tr}_{\mathcal{H}}((R + S)P_n) - 2\text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q(P_n \otimes P_n))\]

since \(P_n \otimes P_n\) is a finite-rank operator (and therefore a compact operator). Thus
\[\lim_{n \to \infty} \langle \Lambda, T_n \rangle = \text{tr}_{\mathcal{H}}(R + S) - 2\text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q) = 2(1 - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q)).\]

Therefore
\[0 \leq 2(1 - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q)) = \lim_{n \to \infty} \langle \Lambda, T_n \rangle = \lim_{n \to \infty} \langle \Lambda, T_n \rangle \leq 1 - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q),\]

so that
\[1 = \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q)\text{ and }\|L\| = \langle \Lambda, I \rangle = \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q) = 1 - \text{tr}_{\mathcal{H} \otimes \mathfrak{H}}(Q) = 0.\]
Summarizing, we have proved that \( \Lambda \) is represented by \( Q \in \mathcal{L}^1(\mathcal{H} \otimes \mathcal{H}) \) such that \( \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q) = 1 \), and the condition \( \Lambda \geq 0 \) implies that \( Q = Q^* \geq 0 \) according to Lemma 3.2. Finally, the definition of \( \Lambda \) implies that

\[
(\Lambda, A \otimes I_\mathcal{H}) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q(A \otimes I_\mathcal{H})) = \text{trace}_{\mathcal{H}}(RA),
\]

\[
(\Lambda, I_\mathcal{H} \otimes B) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q(I_\mathcal{H} \otimes B)) = \text{trace}_{\mathcal{H}}(SB),
\]

so that the partial traces of \( Q \) are \( Q_1 = R \) and \( Q_2 = S \), meaning that \( Q \in \mathcal{C}(R, S) \). This concludes the proof of Lemma 3.3.

At this point, we have proved that the minimizing linear functional \( \Lambda \) in the duality formula above is represented by \( Q \in \mathcal{C}(R, S) \). In other words,

\[
\sup_{(A, B) \in \mathcal{R}} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(RA + SB) = \min_{Q \in \mathcal{C}(R, S)} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QC),
\]

with the notation

\[
\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QC) := \sup_{T \in \mathcal{T}^* \in \mathcal{C}} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QT),
\]

where the constraint \( T \leq C \) has the meaning recalled above. Let us prove that

\[
\sup_{T \in \mathcal{T}^* \in \mathcal{C}} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QT) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q^{1/2}CQ^{1/2}).
\]

Let \( (\Phi_k)_{k \geq 0} \) be a complete orthonormal system of eigenvectors of \( Q \), and let \( (\lambda_k)_{k \geq 0} \) be the sequence of eigenvalues of \( Q \) such that \( Q\Phi_k = \lambda_k \Phi_k \) for each \( k \geq 0 \).

With the notation in section A, one has, by Lemma 2.1,

\[
2h \sum_{k \geq 0} \sum_{m_1, \ldots, m_d \geq 0} \lambda_k (2(n_1 + \ldots + n_d) + d) |(\Psi_{m_1, \ldots, n_d, n_1, \ldots, n_d} | \Phi_k)^2
\]

\[
= \sum_{k \geq 0} \lambda_k |\Phi_k| |C| \Phi_k | \leq 2 \sum_{k \geq 0} \lambda_k |\Phi_k| \| I \otimes H + I \otimes H | \Phi_k | < \infty.
\]

By Corollary C.2, one has \( C_N := (I_\mathcal{H} \otimes \mathcal{H} + C^{-1}) C = C_N^* \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H}) \) for each \( N \geq 1 \), and

\[
\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QC_N) \rightarrow \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q^{1/2}CQ^{1/2}) \quad \text{as} \quad N \rightarrow \infty.
\]

Since \( 0 \leq C_N = C_N^* \leq C \) for each \( N \geq 1 \),

\[
\lim_{N \rightarrow \infty} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(C_N Q) \leq \sup_{T \in \mathcal{T}^* \in \mathcal{C}} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(QT) = \sup_{(A, B) \in \mathcal{R}} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(RA + SB).
\]

On the other hand, since \( \lambda_k > 0 \implies \Psi_k \in \text{Form-Dom}(H \otimes I + I \otimes H) \subset \text{Form-Dom}(C) \), for each \( (A, B) \in \mathcal{R} \), one has

\[
\sum_{k \geq 0} \lambda_k |\Psi_k| |A \otimes I_\mathcal{H} + I_\mathcal{H} \otimes B| | \Psi_k | \leq \sum_{k \geq 0} \lambda_k |\Psi_k| |C| | \Psi_k |,
\]

or equivalently, since \( Q \in \mathcal{C}(R, S) \),

\[
\text{trace}_{\mathcal{H}}(RA + SB) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q^{1/2}(A \otimes I_\mathcal{H} + I_\mathcal{H} \otimes B)Q^{1/2})
\]

\[
\leq \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(Q^{1/2}CQ^{1/2}).
\]

The inequalities (35), (36) and (37) obviously imply (34), and this concludes the proof if Theorem 2.2.
4. Proof of Theorem 2.4

Let \((A_k, B_k) \in \mathcal{R}\) be a maximizing sequence, i.e.

\[
\text{trace}(RA_k + SB_k) \rightarrow \sup_{(A, B) \in \mathcal{R}} \text{trace}(RA + SB) =: \tau \in [0, +\infty) \quad \text{as} \quad k \rightarrow \infty.
\]

That \(\tau < +\infty\) comes from the fact that the inf in Theorem 2.2 is attained by some optimal coupling \(F \in \mathcal{C}(R, S)\), and that \(R\) and \(S\) both belong to \(\mathcal{D}_2(\mathcal{F})\). Indeed, using Lemma C.3 shows that

\[
F \in \mathcal{C}(R, S) \implies 0 \leq \text{trace}(F^{1/2}CF^{1/2}) \leq 2\text{trace}(F^{1/2}(H \otimes I + I \otimes H)F^{1/2}) \\
= 2\text{trace}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2}) < +\infty.
\]

4.1. Step 1: normalizing the maximizing sequence. For each \(k \geq 1\), set

\[
a_k := 2H - A_k \quad \text{and} \quad b_k = 2H - B_k.
\]

Thus

\[
a_k \otimes I + I \otimes b_k \geq 2(H \otimes I + I \otimes H) - C
\]

\[
= \sum_{j=1}^{d} \left( \left( -i\hbar \partial_{x_j} - i\hbar \partial_{y_j} \right)^2 + (x_j + y_j)^2 \right) =: \Sigma \geq 0.
\]

The operator \(\Sigma\) satisfies the same uncertainty inequality as \(C\):

\[
\Sigma = \sum_{j=1}^{d} \left( (x_j + y_j) + i(-i\hbar \partial_{x_j} - i\hbar \partial_{y_j}) \right) \left( (x_j + y_j) - i(-i\hbar \partial_{x_j} - i\hbar \partial_{y_j}) \right)
\]

\[
+ \sum_{j=1}^{d} i \left( [i(-i\hbar \partial_{x_j}, x_j) + [i(-i\hbar \partial_{y_j}, y_j)] \right) \geq 2dH \otimes I,
\]

and

\[
\text{Form-Dom}(\Sigma) = \{ \psi \in \mathcal{F} \otimes \mathcal{F} \text{ s.t. } (x_j + y_j)\psi \text{ and } (\partial_{x_j} + \partial_{y_j})\psi \in \mathcal{F} \otimes \mathcal{F}, 1 \leq j \leq d \}.
\]

Set \(\alpha_k := \sup\{ \alpha \in \mathbb{R} \text{ s.t. } a_k \geq \alpha I \}\) for each \(k \geq 1\). Since \(H = H^* \geq 0\), one has \(a_k \geq -A_k \geq -\|A_k\|I\), so that \(\alpha_k \geq -\|A_k\|\). On the other hand, let \(e_0\) be a normalized eigenvector of \(R\) such that \(Re_0 \neq 0\). Since \(R \in \mathcal{D}_2(\mathcal{F})\), one has \(0 \leq \langle e_0 | H | e_0 \rangle < +\infty\) by (57) (see Lemma C.1 in the Appendix), so that

\[
a_k \geq \alpha I \implies \alpha \leq \langle e_0 | a_k | e_0 \rangle \leq 2\langle e_0 | H | e_0 \rangle + \|A_k\|.
\]

Hence \(\alpha_k \in \left[-\|A_k\|, 2\langle e_0 | H | e_0 \rangle + \|A_k\|\right]\). By definition of \(\alpha_k\), there exists \(\phi_n \in \text{Dom}(H)\) such that

\[
\|\phi_n\|_{\mathcal{F}} = 1 \quad \text{and} \quad \langle \phi_n | a_k | \phi_n \rangle \rightarrow \alpha_k \quad \text{as} \quad n \rightarrow \infty \quad \text{for each} \quad k \geq 1.
\]

Thus

\[
\langle \phi_n | a_k | \phi_n \rangle I + b_k \geq 2dH I \quad \text{for each} \quad n \geq 1,
\]

so that

\[
\alpha_k I + b_k \geq 2dH I.
\]

On the other hand, again by definition of \(\alpha_k\), one has

\[
a_k - \alpha_k I \geq 0.
\]

Setting

\[
\hat{a}_k := a_k - \alpha_k I + dH, \quad \hat{b}_k := b_k + \alpha_k I - dH,
\]
one has
\[ \hat{a}_k \otimes I + I \otimes \hat{b}_k = a_k \otimes I + I \otimes b_k \geq \Sigma, \]
\[ \hat{a}_k = \hat{a}_k^* \geq \text{d}hI, \quad \hat{b}_k = \hat{b}_k^* \geq \text{d}hI. \]
Finally
\[
0 \leq \text{trace}_\beta(R^{1/2} \hat{a}_k R^{1/2} + S^{1/2} \hat{b}_k S^{1/2}) = \text{trace}_\beta(R^{1/2} a_k R^{1/2} + S^{1/2} b_k S^{1/2})
\]
\[= 2 \text{trace}_\beta(R^{1/2} H R^{1/2} + S^{1/2} H S^{1/2}) - \text{trace}_\beta(\text{RA}_k + \text{SB}_k)
\]
\[\to 2 \text{trace}_\beta(R^{1/2} H R^{1/2} + S^{1/2} H S^{1/2}) - \tau
\]
as \( k \to \infty. \)

4.2. **Step 2: defining the unbounded operators** \( a \) **and** \( b.** With the minimizing sequence \((a_k, b_k)\) replaced with its normalized variant \((\hat{a}_k, \hat{b}_k)\) as explained in the previous section, one has
\[
0 \leq \text{trace}(R^{1/2} \hat{a}_k R^{1/2}) \leq \sup_k \text{trace}(R^{1/2} \hat{a}_k R^{1/2}) < +\infty,
\]
\[
0 \leq \text{trace}(S^{1/2} \hat{b}_k S^{1/2}) \leq \sup_k \text{trace}(S^{1/2} \hat{b}_k S^{1/2}) < +\infty,
\]
since both these sequences are converging as \( k \to \infty. \) Therefore, the sequences of operators \( R^{1/2} \hat{a}_k R^{1/2} \) and \( S^{1/2} \hat{b}_k S^{1/2} \) are bounded in \( \mathcal{L}^1(\mathfrak{J}). \) Since \( \mathcal{L}^1(\mathfrak{J}) \) is the topological dual of \( \mathcal{K}(\mathfrak{J}) \) (the algebra of compact operators on \( \mathfrak{J} \)), the Banach-Alaoglu theorem implies that there exists a subsequence of \((\hat{a}_k, \hat{b}_k)\) (abusively denoted \((\hat{a}_k, \hat{b}_k)\) for simplicity) such that
\[
R^{1/2} \hat{a}_k R^{1/2} \to V \quad \text{and} \quad S^{1/2} \hat{b}_k S^{1/2} \to W \quad \text{in} \quad \mathcal{L}^1(\mathfrak{J}) \quad \text{weak-* as} \quad k \to \infty.
\]
Since
\[
\hat{a}_k = \hat{a}_k^* \geq \text{d}hI \quad \text{and} \quad \hat{b}_k = \hat{b}_k^* \geq \text{d}hI,
\]
one has
\[
V = V^* \geq \text{d}hR \quad \text{and} \quad W = W^* \geq \text{d}hS.
\]
In particular
\[
\text{Ker}(V) \subset \text{Ker}(R) \quad \text{and} \quad \text{Ker}(W) \subset \text{Ker}(S).
\]
On the other hand
\[
\text{ran}(V) \subset \overline{\text{ran}(R^{1/2}) = \text{ran}(R)} \quad \text{and} \quad \text{ran}(W) \subset \overline{\text{ran}(S^{1/2}) = \text{ran}(S)}.
\]
(To check the first inclusion, pick \( \xi = Vx \), and observe that
\[
\langle y R^{1/2} \hat{a}_k R^{1/2} | x \rangle = \text{trace}(R^{1/2} \hat{a}_k R^{1/2} | x \rangle (y) \to \langle y | V | x \rangle
\]
so that \( \xi_k = R^{1/2} \hat{a}_k R^{1/2} x \in \text{ran}(R^{1/2}) \) satisfies \( \xi_k \to \xi \) weakly in \( \mathfrak{J}. \) Hence \( \xi \) belongs to the weak closure of \( \text{ran}(R^{1/2}) \), which is equal to its strong closure \( \text{ran}(R^{1/2}) \) since \( \text{ran}(R^{1/2}) \) is a convex subset of \( \mathfrak{J} \): see Theorem 3.7 in [5].) Since
\[
\text{Ker}(V)^+ = \overline{\text{ran}(V)} \subset \overline{\text{ran}(R)} = \text{Ker}(R)^+ \quad \text{and} \quad \text{Ker}(W)^+ = \overline{\text{ran}(W)} \subset \overline{\text{ran}(S)} = \text{Ker}(S)^+,
\]
(see Corollary 2.18 (iv) in [5]) one has
\[
\text{Ker}(V) = \text{Ker}(R) \quad \text{and} \quad \text{ran}(V) = \text{Ker}((R)^\perp),
\]
\[
\text{Ker}(W) = \text{Ker}(S) \quad \text{and} \quad \text{ran}(W) = \text{Ker}((S)^\perp).
\]
In particular
\[
V \in \mathcal{L}^1(\text{Ker}(R)^\perp) \quad \text{and} \quad W \in \mathcal{L}^1(\text{Ker}(S)^\perp).
\]
Let \(v \in \mathcal{L}(\mathcal{J}[R], \mathcal{J}[R]^\perp)\) and \(w \in \mathcal{L}(\mathcal{J}[S], \mathcal{J}[S]^\perp)\) be the operators associated to \(V\) and \(W\) by (26); since \(V = V^*\) and \(W = W^*\), one has
\[
v^* = v \quad \text{and} \quad w^* = w.
\]
Next
\[
\mathcal{J}_0[R] \otimes \mathcal{J}_0[S] \subset \text{Form-Dom}(H \otimes I + I \otimes H) \subset \text{Form-Dom}(\Sigma)
\]
where the first inclusion comes from (27), and the second from (18) and (39). By construction, the sequences \((\hat{a}_k)_{k \geq 1}\) and \((\hat{b}_k)_{k \geq 1}\) satisfy
\[
\langle \Phi | \hat{a}_k \otimes I + I \otimes \hat{b}_k - \Sigma | \Phi \rangle \geq 0 \quad \text{for all } \Phi \in \mathcal{J}_0[R] \otimes \mathcal{J}_0[S].
\]
For each \(\phi \in \mathcal{J}_0[R]\), there exists a unique \(\tilde{\phi} \in \mathcal{J}_0[R]\) such that \(R^{1/2}\tilde{\phi} = \phi\), so that
\[
\langle \phi | \hat{a}_k | \phi \rangle = \langle \tilde{\phi} | R^{1/2}\hat{a}_k R^{1/2} \tilde{\phi} \rangle \rightarrow \langle \tilde{\phi} | V \tilde{\phi} \rangle = \langle \phi | v | \phi \rangle \quad \text{as } k \rightarrow \infty.
\]
Likewise \(\langle \psi | \hat{b}_k | \psi \rangle \rightarrow \langle \psi | w | \psi \rangle\) as \(k \rightarrow \infty\) for each \(\psi \in \mathcal{J}_0[R]\). Passing to the limit in the last inequality implies that
\[
\langle \Phi | v \otimes I + I \otimes w - \Sigma | \Phi \rangle \geq 0 \quad \text{for all } \Phi \in \mathcal{J}_0[R] \otimes \mathcal{J}_0[S].
\]
Let \(a = a^* \in \mathcal{L}(\mathcal{J}[R], \mathcal{J}[R]^\perp)\) and \(b = b^* \in \mathcal{L}(\mathcal{J}[S], \mathcal{J}[S]^\perp)\) be the operators associated to \(2R^{1/2}HR^{1/2} - V \in \mathcal{L}^1((\text{Ker}(R)^\perp))\) and to \(2S^{1/2}HS^{1/2} - W \in \mathcal{L}^1((\text{Ker}(S)^\perp))\) respectively. The last inequality on \(v\) and \(w\) implies that \((a, b) \in \mathcal{R}(R, S)\).

4.3. Step 3: relaxing the constraint. In this step we prove the following: for each \((\hat{a}, \hat{b}) \in \mathcal{R}(R, S)\) and each \(F \in \mathcal{C}(R, S)\), one has
\[
\text{trace}_{S \otimes D}(F^{1/2}C F^{1/2}) \geq \text{trace}_{S}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}).
\]
Let \((e_j')\) and \((f_j')\) be orthonormal sequences of eigenvectors of \(R\) and \(S\) belonging to \(\mathcal{J}_0[R]\) and \(\mathcal{J}_0[S]\), and assumed to be complete in \(\text{Ker}(R)^\perp\) and \(\text{Ker}(S)^\perp\) respectively. Call \(p_m\) and \(q_n\) the orthogonal projections on the \(m\) first elements of \((e_j')\) and on the \(n\) first elements of \((f_j')\) respectively, so that
\[
0 \leq p_1 \leq \ldots \leq p_m \leq \sup_m p_m = \mathcal{P} = \text{orthogonal projection on ker}(R)^\perp,
\]
\[
0 \leq q_1 \leq \ldots \leq q_n \leq \sup_n q_n = \mathcal{Q} = \text{orthogonal projection on ker}(S)^\perp.
\]
We shall argue instead in terms of the operators
\[
\tilde{v} = \tilde{v}^* \in \mathcal{L}(\mathcal{J}[R], \mathcal{J}[R]^\perp) \quad \text{and} \quad \tilde{w} = \tilde{w}^* \in \mathcal{L}(\mathcal{J}[S], \mathcal{J}[S]^\perp)
\]
associated by (26) to the operators
\[
R^{1/2}HR^{1/2} - R^{1/2}aR^{1/2} \in \mathcal{L}^1(\text{Ker}(R)^\perp),
\]
\[
S^{1/2}HS^{1/2} - S^{1/2}bS^{1/2} \in \mathcal{L}^1(\text{Ker}(S)^\perp).
\]
Since \((\bar{a}, \bar{b}) \in \mathcal{H}(R, S)\), one has \(\langle \Phi | C - \bar{a} \otimes I - I \otimes \bar{b} | \Phi \rangle \geq 0\) for each \(\Phi \in \mathcal{J}_0[R] \otimes \mathcal{J}_0[S]\), so that, for each \(m, n\), one has
\[
\begin{align*}
 p_m \otimes q_n \Sigma_N \bar{p}_m \otimes q_n & \leq p_m \otimes q_n \Sigma_N \bar{p}_m \otimes q_n \leq (p_m \bar{v}_m \otimes p_m) \otimes q_n + p_m \otimes (q_n \bar{w}_n q_n) \\
& \leq (p_m \bar{v}_m \otimes p_m) \otimes \Omega + \bar{\mathcal{P}} \otimes (q_n \bar{w}_n q_n),
\end{align*}
\]
where \(\Sigma_N := (I_{\mathcal{H}} \otimes \frac{1}{\sqrt{N}} \Sigma) - I = \Sigma_N^* \in \mathcal{L}(\mathcal{H} \otimes \mathcal{H})\) and \(0 \leq \Sigma_N \leq \Sigma\) for each \(N \geq 1\).

That \((p_m \bar{v}_m \otimes q_n) \leq (p_m \bar{v}_m \otimes p_m) \otimes \Omega\) is seen easily, for instance by the following argument. Let \(\Phi\) be any element of \(\text{Ker}(R)^4 \otimes \text{Ker}(S)^4\), which we decompose on the complete orthonormal system \((e'_j \otimes f'_l)\):
\[
\Phi = \sum_{j,l} \Phi_{j,l} e'_l \otimes f'_j, \quad \sum_{j,l} |\Phi_{j,l}|^2 = |\Phi|_{\mathcal{H} \otimes \mathcal{H}}^2 < \infty.
\]
Then
\[
\langle \Phi | (p_m \bar{v}_m \otimes q_n) | \Phi \rangle = \sum_{1 \leq j,k \leq m, 1 \leq l \leq n} \overline{\Phi}_{j,l} \langle \bar{v}_j | e'_k \rangle \langle e'_j | f'_k \rangle \langle f'_l | v_l \rangle \langle v_l | \bar{w}_m \bar{w}_n \rangle \leq \sum_{l} \sum_{1 \leq j,k \leq m} \overline{\Phi}_{j,l} \langle \bar{v}_j | e'_k \rangle \langle e'_j | f'_k \rangle \langle f'_l | v_l \rangle \langle v_l | \bar{w}_m \bar{w}_n \rangle = \langle \Phi | p_m \bar{v}_m \otimes \Omega | \Phi \rangle,
\]
since the matrix \(((\langle \bar{v}_j | e'_k \rangle \langle e'_j | f'_k \rangle \langle f'_l | v_l \rangle \langle v_l | \bar{w}_m \bar{w}_n \rangle)_{1 \leq j,k \leq m})\) is Hermitian nonnegative. The analogous inequality for \(\bar{w}\) is proved similarly.

Thus, for each \(F \in \mathcal{C}(R, S)\), one has
\[
\text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(p_m \otimes q_n) \Sigma (p_m \otimes q_n)) \leq \text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|p_m \bar{v}_m \otimes \Omega|) + \bar{\mathcal{P}} \otimes (q_n \bar{w}_n q_n)).
\]

**Lemma 4.1.** Let \(R, S \in \mathcal{D}(\mathcal{H})\) and let \(\mathcal{P}\) and \(\Omega\) be the orthogonal projections on \(\text{Ker}(R)^4\) and \(\text{Ker}(S)^4\) respectively. For each \(F \in \mathcal{C}(R, S)\), one has
\[
F = (\mathcal{P} \otimes \Omega) F (\mathcal{P} \otimes \Omega).
\]

Taking this lemma for granted, we conclude the proof of (40). First
\[
\begin{align*}
\text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|p_m \bar{v}_m \otimes \Omega|)) &= \text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|\mathcal{P} \otimes \Omega|) (|p_m \bar{v}_m \otimes I|) (|\mathcal{P} \otimes \Omega|)) \\
&= \text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|\mathcal{P} \otimes \Omega|) F(|\mathcal{P} \otimes \Omega|) (|p_m \bar{v}_m \otimes I|)) \\
&= \text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|p_m \bar{v}_m \otimes I|)) \\
&= \text{tr}\Sigma_{\mathcal{H}}(R(p_m \bar{v}_m)) = \text{tr}\Sigma_{\mathcal{H}}(R^{1/2}(p_m \bar{v}_m)R^{1/2}) \\
&= \text{tr}\Sigma_{\mathcal{H}}(p_m R^{1/2} \bar{v} R^{1/2} p_m) \leq \text{tr}\Sigma_{\mathcal{H}}(R^{1/2} \bar{v} R^{1/2})
\end{align*}
\]
where the first equality comes from the fact that \(\mathcal{P} p_m = p_m = \mathcal{P} \bar{p}_m\), the second and the fifth equality follow by cyclicity of the trace, the third equality from the lemma above, the fourth equality from the fact that \(F \in \mathcal{C}(R, S)\), and the sixth equality from the fact that \(p_m\) is a spectral projection of \(R\) and therefore commutes with \(R\). The last inequality is obtained by computing the trace of \(R^{1/2} \bar{v} R^{1/2} \in \mathcal{L}(\mathcal{H})\) on a complete orthonormal system in \(\mathcal{H}\) whose \(m\) first vectors span \(\text{ran}(p_m)\). By the same token,
\[
\begin{align*}
\text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|\mathcal{P} \otimes (q_n \bar{w}_n)|)) &\leq \text{tr}\Sigma_{\mathcal{H}}(S^{1/2} \bar{w} S^{1/2})
\end{align*}
\]
On the other hand
\[
\text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(p_m \otimes q_n) \Sigma_N (p_m \otimes q_n)) \to \text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(|\mathcal{P} \otimes \Omega|) \Sigma_N (|\mathcal{P} \otimes \Omega|))
\]
\[
= \text{tr}\Sigma_{\mathcal{H} \otimes \mathcal{S}}(F(\Sigma_N))
\]
passing to the limit in \(m, n\) for each \(N \geq 1\). Indeed
\[
(p_m \otimes q_n) \Sigma_N (p_m \otimes q_n) \to (\mathcal{P} \otimes \Omega) \Sigma_N (\mathcal{P} \otimes \Omega) \quad \text{strongly in } \mathcal{L}(\mathcal{H} \otimes \mathcal{H})
\]
for each $N \geq 1$, since for each $\Psi \in \mathcal{H} \otimes \mathcal{H}$
\[
\|(\Psi \otimes \Omega)\Sigma_N(\Psi \otimes \Omega)\Psi - (p_m \otimes q_n)\Sigma_N(p_m \otimes q_n)\Psi\| \\
\leq \|(\Psi \otimes \Omega - p_m \otimes q_n)\Sigma_N(\Psi \otimes \Omega)\Psi\| \\
+ \|(p_m \otimes q_n)\Sigma_N(\Psi \otimes \Omega - p_m \otimes q_n)\Psi\| \\
\leq \|(\Psi \otimes \Omega - p_m \otimes q_n)\Sigma_N(\Psi \otimes \Omega)\Psi\| \\
+ \|\Sigma_N\|\|(\Psi \otimes \Omega - p_m \otimes q_n)\Psi\| \to 0
\]
in $m, n$ for each $N \geq 1$. Then, one concludes as in Example 3 of chapter 2 in [22].

Thus, we have proved that
\[
\text{trace}_{\mathcal{B} \otimes \mathcal{B}}(F\Sigma_N) \leq \text{trace}_{\mathcal{B}}(R^{1/2}vR^{1/2} + S^{1/2}wS^{1/2}), \quad \text{for each } N \geq 1.
\]
By Corollary C.2, $\text{trace}_{\mathcal{B} \otimes \mathcal{B}}(F\Sigma_N) \to \text{trace}_{\mathcal{B} \otimes \mathcal{B}}(F^{1/2}\Sigma F^{1/2})$ as $N \to \infty$, so that
\[
\text{trace}_{\mathcal{B} \otimes \mathcal{B}}(F^{1/2}\Sigma F^{1/2}) \leq \text{trace}_{\mathcal{B}}(R^{1/2}vR^{1/2} + S^{1/2}wS^{1/2}),
\]
which is equivalent to the sought inequality (40).

4.4. **Step 4: the squeezing argument.** Pick an optimal coupling $F_{\text{opt}} \in C(R, S)$. (We recall that the existence of such a coupling is one of the conclusions of Theorem 2.2, and follows from the Fenchel-Rockafellar duality theorem.) One has the following chain of inequalities:
\[
\text{sup}_{(A, B) \in \mathcal{R}} \text{trace}_{\mathcal{B}}(RA + SB) \leq \text{sup}_{(\tilde{a}, \tilde{b}) \in \tilde{\mathcal{R}}(R, S)} \text{trace}_{\mathcal{B}}(\tilde{a}R^{1/2} + \tilde{b}S^{1/2}) \\
\leq \text{trace}_{\mathcal{B} \otimes \mathcal{B}}(F_{\text{opt}}^{1/2}CF_{\text{opt}}^{1/2}.
\]
(41)
The second inequality has been proved in Step 3.

As for the first inequality, observe first that
\[
\text{sup}_{(A, B) \in \mathcal{R}} \text{trace}_{\mathcal{B}}(RA + SB) = \text{sup}_{(A, B) \in \tilde{\mathcal{R}}} \text{trace}_{\mathcal{B}}(RA + SB),
\]
with the notation
\[
\tilde{\mathcal{R}} := \{(A, B) \in \mathcal{R} \text{ s.t. } A \leq 2H - dhI \text{ and } B \leq 2H - dhI\}.
\]
This is proved by the normalization argument in Step 1: pick
\[
\rho := \sup\{\alpha \in \mathbb{R} \text{ s.t. } 2H - A \geq \alpha I\}.
\]
Then $\rho \in [-\|A\|, 2(e_0\|H\|e_0) + \|A\|]$, where $e_0$ is a normalized eigenvector of $R$ such that $Re_0 \neq 0$, and one has
\[
A + (\rho - dh)I \leq 2H - dhI \quad \text{and} \quad B - (\rho - dh)I \leq 2H - dhI
\]
by the same argument as in Step 1. (Indeed, by definition of $\rho$, there exists a sequence $\phi_n \in \text{Dom}(H)$ such that $\|\phi_n\|_H = 1$ and $\langle \phi_n|2H - A|\phi_n \rangle \to \rho$ as $n \to \infty$. With the inequality $A \otimes I + I \otimes B \leq C$, this implies that, for each $\psi \in \text{Dom}(H)$, one has
\[
\rho\|\psi\|^2_H + \langle \psi|2H - B|\psi \rangle \geq \langle \phi_n| \otimes \psi|2(H \otimes I + I \otimes H) - C|\phi_n \otimes \psi \rangle \geq 2dh\|\psi\|^2_H,
\]
since $2(H \otimes I + I \otimes H) - C \geq 2dhI \otimes I$.) Observing that
\[
(A, B) \in \tilde{\mathcal{R}} \implies (A + (\rho - dh)I, B - (\rho - dh)I) \in \tilde{\mathcal{R}},
\]
and that
\[
\text{trace}_{\mathcal{B}}(RA + SB) = \text{trace}_{\mathcal{B}}(R(A + (\rho - dh)I) + S(B - (\rho - dh)I))
\]
leads to (42).
Let \( \mathfrak{P} \) and \( \mathfrak{Q} \) be the \( \mathfrak{H} \)-orthogonal projections on \( \text{Ker}(R)^\perp \) and \( \text{Ker}(S)^\perp \) respectively, as in the previous section. We claim that

\[
(A, B) \in \hat{\mathfrak{K}} \implies (\mathfrak{P}A\mathfrak{P}, \mathfrak{Q}B\mathfrak{Q}) \in \tilde{\mathfrak{K}}(R, S).
\]

Indeed

\[
\mathfrak{P}A\mathfrak{P} = (\mathfrak{P}A\mathfrak{P})^* \in \mathcal{L}(\text{Ker}(T)^\perp) \subset \mathcal{L}(\mathcal{J}[R], \mathcal{J}[R]')
\]

\[
\mathfrak{Q}B\mathfrak{Q} = (\mathfrak{Q}B\mathfrak{Q})^* \in \mathcal{L}(\text{Ker}(S)^\perp) \subset \mathcal{L}(\mathcal{J}[S], \mathcal{J}[S]')
\]

because of the double continuous embedding (24). Then

\[
2H \geq A \implies 2R^{1/2}HR^{1/2} \geq R^{1/2}AR^{1/2} = R^{1/2}\mathfrak{P}A\mathfrak{P}R^{1/2}
\]

\[
2H \geq B \implies 2S^{1/2}HS^{1/2} \geq S^{1/2}BS^{1/2} = S^{1/2}\mathfrak{Q}B\mathfrak{Q}S^{1/2}
\]

since \( \mathfrak{P}R^{1/2} = R^{1/2}\mathfrak{P} = R^{1/2} \) and \( \mathfrak{Q}S^{1/2} = S^{1/2}\mathfrak{Q} = S^{1/2} \), and

\[
\text{trace}_{\mathfrak{B}}(2R^{1/2}HR^{1/2} - R^{1/2}\mathfrak{P}A\mathfrak{P}R^{1/2}) \\
\leq \text{trace}_{\mathfrak{B}}(2R^{1/2}HR^{1/2}) + \|A\| < +\infty,
\]

\[
\text{trace}_{\mathfrak{B}}(2S^{1/2}HS^{1/2} - S^{1/2}\mathfrak{Q}B\mathfrak{Q}S^{1/2}) \\
\leq \text{trace}_{\mathfrak{B}}(2S^{1/2}HS^{1/2}) + \|B\| < +\infty,
\]

so that

\[
2R^{1/2}HR^{1/2} - R^{1/2}\mathfrak{P}A\mathfrak{P}R^{1/2} \in \mathcal{L}^1(\text{Ker}(R)^\perp),
\]

\[
2S^{1/2}HS^{1/2} - S^{1/2}\mathfrak{Q}B\mathfrak{Q}S^{1/2} \in \mathcal{L}^1(\text{Ker}(S)^\perp).
\]

Finally, the inequality

\[
(\Phi|A \otimes I + I \otimes B|\Phi) \leq (\Phi|C|\Phi)
\]

holds for all \( \Phi \in \mathcal{J}_0[R] \otimes \mathcal{J}_0[S] \subset \text{Form-Dom}(C) \). Observe that

\[
\Phi \in \mathcal{J}_0[R] \otimes \mathcal{J}_0[S] \implies ((I - \mathfrak{P}) \otimes I)\Phi = (I \otimes (I - \mathfrak{Q}))\Phi = 0,
\]

and therefore

\[
(\Phi|\mathfrak{P}A\mathfrak{P}) \otimes I + I \otimes (\mathfrak{Q}B\mathfrak{Q})|\Phi) \leq (\Phi|C|\Phi)
\]

for all \( \Phi \in \mathcal{J}_0[R] \otimes \mathcal{J}_0[S] \), so that \( (\mathfrak{P}A\mathfrak{P}, \mathfrak{Q}B\mathfrak{Q}) \in \tilde{\mathfrak{K}}(R, S) \).

Since \( \mathfrak{P}R^{1/2} = R^{1/2}\mathfrak{P} = R^{1/2} \) and \( \mathfrak{Q}S^{1/2} = S^{1/2}\mathfrak{Q} = S^{1/2} \), one has

\[
\text{trace}_{\mathfrak{B}}(RA + SB) = \text{trace}_{\mathfrak{B}}(R^{1/2}\mathfrak{P}A\mathfrak{P}R^{1/2} + S^{1/2}\mathfrak{Q}B\mathfrak{Q}S^{1/2}),
\]

we conclude that

\[
\sup_{(A, B) \in \hat{\mathfrak{K}}} \text{trace}(RA + SB) \leq \sup_{(\tilde{a}, \tilde{b}) \in \tilde{\mathfrak{K}}(R, S)} \text{trace}(R^{1/2}\tilde{a}R^{1/2} + S^{1/2}BS^{1/2}) .
\]

Then (42) and (43) imply the chain of inequalities (41). By the quantum duality theorem (Theorem 2.2), all the inequalities in (41) are equalities:

\[
\sup_{(A, B) \in \hat{\mathfrak{K}}} \text{trace}_{\mathfrak{B}}(RA + SB) = \sup_{(\tilde{a}, \tilde{b}) \in \tilde{\mathfrak{K}}(R, S)} \text{trace}_{\mathfrak{B}}(R^{1/2}\tilde{a} + S^{1/2}\tilde{b}S^{1/2})
\]

\[
= \text{trace}_{\mathfrak{B} \otimes \mathfrak{B}}(F_{\text{opt}}^{1/2}C F_{\text{opt}}^{1/2}) .
\]
4.5. **Step 5: the pair \((a, b) \in \tilde{\Omega}(R, S)\) is optimal.** For each finite rank orthogonal projection \(P = P^* = P^2 \in L(\mathcal{F})\), one has

\[
\text{trace}_{\mathcal{F}}(PR^{1/2}VR^{1/2}P) = \text{trace}_{\mathcal{F}}(PR^{1/2}aR^{1/2})
\]

\[
= \lim_{k \to \infty} \text{trace}_{\mathcal{F}}(PR^{1/2}\tilde{a}_k R^{1/2}) = \lim_{k \to \infty} \text{trace}_{\mathcal{F}}(PR^{1/2}\tilde{a}_k R^{1/2}P),
\]

\[
\text{trace}_{\mathcal{F}}(PS^{1/2}wS^{1/2}P) = \text{trace}_{\mathcal{F}}(PS^{1/2}wS^{1/2})
\]

\[
= \lim_{k \to \infty} \text{trace}_{\mathcal{F}}(PR^{1/2}\tilde{a}_k R^{1/2}) = \lim_{k \to \infty} \text{trace}_{\mathcal{F}}(PR^{1/2}\tilde{a}_k R^{1/2}P),
\]

since

\[
R^{1/2}\tilde{a}_k R^{1/2} \to V = R^{1/2}VR^{1/2} \text{ and } S^{1/2}\tilde{b}_k S^{1/2} \to W = S^{1/2}wS^{1/2}
\]
in \(L^1(\mathcal{F})\) weak-* by construction.

Since \(\tilde{a}_k = \tilde{a}_k^* \geq 0\) and \(\tilde{b}_k = \tilde{b}_k^* \geq 0\) for each \(k \geq 0\) (by construction), one has

\[
\text{trace}_{\mathcal{F}}(PR^{1/2}\tilde{a}_k R^{1/2}P) = \|PR^{1/2}\tilde{a}_k R^{1/2}P\|_1
\]

\[
\leq \|R^{1/2}\tilde{a}_k R^{1/2}\|_1 = \text{trace}_{\mathcal{F}}(R^{1/2}\tilde{a}_k R^{1/2}),
\]

\[
\text{trace}_{\mathcal{F}}(PS^{1/2}\tilde{b}_k S^{1/2}P) = \|PS^{1/2}\tilde{b}_k S^{1/2}P\|_1
\]

\[
\leq \|S^{1/2}\tilde{b}_k S^{1/2}\|_1 = \text{trace}_{\mathcal{F}}(S^{1/2}\tilde{b}_k S^{1/2}).
\]

Thus, for each finite rank \(P = P^* = P^2 \in L(\mathcal{F})\), one has

\[
\text{trace}_{\mathcal{F}}(PR^{1/2}VR^{1/2} + S^{1/2}wS^{1/2}P) \leq \lim_{k \to \infty} \text{trace}_{\mathcal{F}}(R^{1/2}\tilde{a}_k R^{1/2} + S^{1/2}\tilde{b}_k S^{1/2})
\]

\[
= \text{trace}_{\mathcal{F}}(2R^{1/2}HR^{1/2} + 2S^{1/2}HS^{1/2} - \tau).
\]

Indeed

\[
\tilde{a}_k = 2H - A_k - \alpha_k I + dhI \text{ and } \tilde{b}_k = 2H - B_k + \alpha_k I - dhI,
\]

so that

\[
\text{trace}_{\mathcal{F}}(R^{1/2}\tilde{a}_k R^{1/2} + S^{1/2}\tilde{b}_k S^{1/2})
\]

\[
= 2 \text{trace}_{\mathcal{F}}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2}) - \text{trace}_{\mathcal{F}}(R^{1/2}A_k R^{1/2} + S^{1/2}B_k S^{1/2})
\]

\[
\to 2 \text{trace}_{\mathcal{F}}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2} - \tau)
\]

by definition of the sequence \((A_k, B_k)\) (which is a maximizing sequence for the right hand side of (21)).

Since \(R^{1/2}VR^{1/2} \in L^1(\mathcal{F})\) and \(S^{1/2}wS^{1/2} \in L^1(\mathcal{F})\), one has

\[
\text{trace}_{\mathcal{F}}(R^{1/2}VR^{1/2} + S^{1/2}wS^{1/2}) = \sup_{P^2 = P, P \in \mathcal{P}} \text{trace}_{\mathcal{F}}(P(R^{1/2}VR^{1/2} + S^{1/2}wS^{1/2}P))
\]

\[
\leq 2 \text{trace}_{\mathcal{F}}(R^{1/2}HR^{1/2} + S^{1/2}HS^{1/2} - \tau).
\]

Equivalently, in terms of \(a\) and \(b\), one has

\[
\text{trace}_{\mathcal{F}}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}) \geq \tau
\]

and we deduce from the first equality in (44) that

\[
\text{trace}_{\mathcal{F}}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}) \geq \sup_{(\tilde{a}, \tilde{b}) \in \tilde{\Omega}(R, S)} \text{trace}_{\mathcal{F}}(R^{1/2}\tilde{a}R^{1/2} + S^{1/2}\tilde{b}S^{1/2}).
\]

Since \((a, b) \in \tilde{\Omega}(R, S)\) as proved at the end of Step 2, the inequality above is an equality and the pair \((a, b)\) is optimal. This concludes the proof of Theorem 2.4.
It remains to prove Lemma 4.1

Proof of Lemma 4.1. One has
\[
\text{trace}_{\mathcal{H}\otimes\mathcal{H}}(((I - \mathcal{H}) \otimes I) F((I - \mathcal{H}) \otimes I)) = \text{trace}_{\mathcal{H}\otimes\mathcal{H}}(((I - \mathcal{H}) \otimes I) F)
\]
\[
= \text{trace}_{\mathcal{H}}((I - \mathcal{H}) R) = 0
\]
since \(I - \mathcal{H}\) is the orthogonal projection on \(\text{Ker}(R)\), so that
\[
((I - \mathcal{H}) \otimes I) F((I - \mathcal{H}) \otimes I) = 0
\]
since \(((I - \mathcal{H}) \otimes I) F((I - \mathcal{H}) \otimes I) = ((I - \mathcal{H}) \otimes I) F((I - \mathcal{H}) \otimes I)^* \geq 0\). Next observe that
\[
\left|\left<\phi \otimes \psi((\mathcal{H} \otimes I) F((I - \mathcal{H}) \otimes I))|\phi' \otimes \psi'\right>^2
\right|
\]
\[
\leq \left<\phi \otimes \psi((\mathcal{H} \otimes I) F(\mathcal{H} \otimes I))|\phi' \otimes \psi'((I - \mathcal{H}) \otimes I) F((I - \mathcal{H}) \otimes I))|\phi' \otimes \psi'\right>
\]
for each \(\phi, \phi', \psi, \psi' \in \mathcal{H}\) by the Cauchy-Schwarz inequality since \(F = F^* \geq 0\), so that
\[
\left<\phi \otimes \psi((\mathcal{H} \otimes I) F((I - \mathcal{H}) \otimes I))|\phi' \otimes \psi'\right> = 0.
\]
Hence
\[
(\mathcal{H} \otimes I) F((I - \mathcal{H}) \otimes I) = (\mathcal{H} \otimes I) F((I - \mathcal{H}) \otimes I)^* = ((I - \mathcal{H}) \otimes I) F(\mathcal{H} \otimes I) = 0,
\]
so that
\[
F = (\mathcal{H} \otimes I) F(\mathcal{H} \otimes I).
\]
The same argument shows that
\[
F = (I \otimes \mathcal{H}) F(I \otimes \mathcal{H}),
\]
so that
\[
F = (I \otimes \mathcal{H}) F(I \otimes \mathcal{H}) = (I \otimes \mathcal{H})(\mathcal{H} \otimes I) F(\mathcal{H} \otimes I)(I \otimes \mathcal{H}) = (\mathcal{H} \otimes \mathcal{H}) F(\mathcal{H} \otimes \mathcal{H}),
\]
which is precisely the desired equality. \(\square\)

5. Proofs of Theorems 2.5 and 2.6

Proof of Theorem 2.5. Since \(\Phi_j \in \text{Ker}(C - A \otimes I - I \otimes B)\), one has in particular \(\Phi_j \in \text{Dom}(C)\) with
\[
\|C\Phi_j\| \leq (\|A\| + \|B\|)\|\Phi_j\| = \|A\| + \|B\| \quad \text{for all } j.
\]
Therefore
\[
\sum_m \lambda_m \langle \Phi_m | C | \Phi_m \rangle \leq (\|A\| + \|B\|) \sum_m \lambda_m = \|A\| + \|B\|,
\]
so that
\[
F^{1/2} C F^{1/2} := \sum_{j,k} \sqrt{\lambda_j \lambda_k} \langle \Phi_j | C | \Phi_k \rangle | \Phi_j \rangle | \Phi_k \rangle \in L^1(\mathcal{H} \otimes \mathcal{H})
\]
by Lemma C.1. Since \(\Phi_k \in \text{Ker}(C - A \otimes I - I \otimes B)\) for all \(k\), one has
\[
F^{1/2} C F^{1/2} := \sum_{j,k} \sqrt{\lambda_j \lambda_k} \langle A \otimes I + I \otimes B | \Phi_k \rangle | \Phi_j \rangle | \Phi_k \rangle = F^{1/2} (A \otimes I + I \otimes B) F^{1/2},
\]
and thus
\[
\text{trace}_{\mathcal{H}\otimes\mathcal{H}}(F^{1/2} C F^{1/2}) = \text{trace}_{\mathcal{H}\otimes\mathcal{H}}(F^{1/2} (A \otimes I + I \otimes B) F^{1/2})
\]
\[
= \text{trace}_{\mathcal{H}\otimes\mathcal{H}}(F(A \otimes I + I \otimes B)) = \text{trace}_{\mathcal{H}}(F_1 A + F_2 B),
\]
where the second equality follows from cyclicity of the trace, while the third equality comes from the definition of \( F_1 \) and \( F_2 \) as the partial traces of \( F \). Therefore

\[
\inf_{G \in \mathcal{C}(F_1, F_2)} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}) \leq \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}CF^{1/2})
\]

\[
= \text{trace}_\mathcal{H}(F_1 A + F_2 B) \leq \sup_{(a, b) \in \mathcal{H}} \text{trace}_\mathcal{H}(F_1 a + F_2 b).
\]

For each \( G \in \mathcal{C}(R, S) \), let \( (\Psi_k)_{k \geq 1} \) be a complete orthonormal system of eigenvectors of \( G \), and let \( (\gamma_k)_{k \geq 1} \) be the sequence of eigenvalues of \( G \), so that \( G\Psi_k = \gamma_k \Psi_k \) for each \( k \geq 1 \). Then

\[
\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}) < \infty \iff \sum_{k \geq 1} \gamma_k |\Psi_k|C|\Psi_k| < \infty.
\]

Thus, if \( \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}) < \infty \), one has, as explained in Lemma 2.1

\[
\Psi_k \in \text{Form-Dom}(C) \text{ for each } k \geq 0 \text{ s.t. } \gamma_k > 0.
\]

For all \((a, b) \in \mathcal{H}\), one has therefore

\[
\gamma_k > 0 \implies \langle \Psi_k |C - a \otimes I - I \otimes b|\Psi_k \rangle \geq 0,
\]

so that

\[
0 \leq \sum_{k \geq 0} \gamma_k |\Psi_k|C - a \otimes I - I \otimes b|\Psi_k|
\]

\[
= \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}) - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}(a \otimes I + I \otimes b)G^{1/2})
\]

\[
= \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}) - \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G(a \otimes I + I \otimes b))
\]

\[
= \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}) - \text{trace}_\mathcal{H}(F_1 a + F_2 b)
\]

Therefore

\[
\sup_{(a, b) \in \mathcal{H}} \text{trace}_\mathcal{H}(F_1 a + F_2 b) \leq \inf_{G \in \mathcal{C}(R, S)} \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(G^{1/2}CG^{1/2}).
\]

Putting together (45) and (46) leads to the announced result. \(\square\)

**Proof of Theorem 2.6.** Since \( F \in \mathcal{C}(R, S) \) with \( R, S \in \mathcal{D}_2(\mathcal{F}) \), any eigenvector \( \Phi \) of \( F \) such that \( F\Phi \neq 0 \) satisfies

\[
\Phi \in \text{Form-Dom}(H \otimes I + I \otimes H) \subset \text{Form-Dom}(C)
\]

by Lemma 2.1. By cyclicity of the trace

\[
\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}(A \otimes I + I \otimes B)F^{1/2}) = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F(A \otimes I + I \otimes B))
\]

\[
= \text{trace}_\mathcal{H}(RA + SB).
\]

Since \( F^{1/2}(H \otimes I + I \otimes H)F^{1/2} \in \mathcal{L}(\mathcal{F} \otimes \mathcal{F}) \) and since \( C \leq 2(H \otimes I + I \otimes H) \) on \( \text{Form-Dom}(H \otimes I + I \otimes H) \), one has

\[
\text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}(C - A \otimes I - I \otimes B)F^{1/2}) = 0.
\]
Let \((\Phi_j)_{j \geq 1}\) be a complete orthonormal sequence of eigenvectors of \(F\), and define \(\lambda_j \geq 0\) by the condition \(F \Phi_j = \lambda_j \Phi_j\), for each \(j \geq 1\). Then

\[
0 = \text{trace}_{\mathcal{H} \otimes \mathcal{H}}(F^{1/2}(C - A \otimes I - I \otimes B)F^{1/2})
= \sum_{j \geq 1} \langle \Phi_j | F^{1/2}(C - A \otimes I - I \otimes B)F^{1/2}| \Phi_j \rangle
= \sum_{j \geq 1} \lambda_j \langle \Phi_j | C - A \otimes I - I \otimes B| \Phi_j \rangle,
\]
so that

\[
\lambda_j > 0 \implies \langle \Phi_j | C - A \otimes I - I \otimes B| \Phi_j \rangle = 0, \quad \text{for all } j \geq 1.
\]

Indeed, since \(\Phi_j \in \text{Form-Dom}(C)\) and \((A, B) \in \mathcal{H}\), one has

\[
\langle \Phi_j | C - A \otimes I - I \otimes B| \Phi_j \rangle \geq 0, \quad \text{for all } j \geq 1.
\]

Since \(\langle \Phi | C - A \otimes I - I \otimes B| \Phi \rangle \geq 0\) for each \(\Phi \in \text{Form-Dom}(C)\), we conclude from the Cauchy-Schwarz inequality that

\[
\lambda_j > 0 \implies \langle \Phi | C - A \otimes I + I \otimes B| \Phi \rangle = 0, \quad \text{for all } j \geq 1 \text{ and } \Phi \in \text{Form-Dom}(C).
\]

In particular, choosing \(\Phi = \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d}\) (in the notation of section A) shows that

\[
2h(2(n_1, \ldots, n_d) + d)\langle \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} | \Phi_j \rangle = \langle \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} | A \otimes I + I \otimes B| \Phi_j \rangle,
\]
so that

\[
4h^2 \sum_{n_1, \ldots, n_d \geq 0} (2(n_1, \ldots, n_d) + d)^2 \langle \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} | \Phi_j \rangle^2 \leq (\|A\| + \|B\|)^2.
\]

This implies that \(\Phi_j \in \text{Dom}(C)\) with \(\|C \Phi_j\| \leq \|A\| + \|B\|\) for each \(j \geq 1\). Hence

\[
\lambda_j > 0 \implies (C - A \otimes I - I \otimes B) \Phi_j \in \mathcal{H} \otimes \mathcal{H},
\]
and

\[
(C - A \otimes I - I \otimes B) \Phi_j \perp \text{Form-Dom}(C).
\]

Since \(\text{Form-Dom}(C)\) is dense in \(\mathcal{H} \otimes \mathcal{H}\), we conclude that \((C - A \otimes I - I \otimes B) \Phi_j = 0\) for all \(j \geq 1\) such that \(\lambda_j > 0\). This proves (a).

For each \(j = 1, \ldots, d\), one has

\[
(\mathcal{D}_{q_j} \otimes I)(C - A \otimes I - I \otimes B) = \mathcal{D}_{q_j}(H - A) \otimes I - 2I \otimes q_j = 2(\mathcal{D}_{q_j}A \otimes I - I \otimes q_j) \in \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)'),
\]

\[
(\mathcal{D}_{p_j} \otimes I)(C - A \otimes I - I \otimes B) = \mathcal{D}_{p_j}(H - A) \otimes I - 2I \otimes p_j = 2(\mathcal{D}_{p_j}A \otimes I - I \otimes p_j) \in \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)').
\]

Applying (31) with \(T = q_j \otimes I, p_j \otimes I, I \otimes q_j, I \otimes p_j\) shows that all these operators, which are bounded from \(\text{Form-Dom}(H \otimes I + I \otimes H)\) into \(\mathcal{H} \otimes \mathcal{H}\), can be extended as bounded operators from \(\mathcal{H} \otimes \mathcal{H}\) to \(\text{Form-Dom}(H \otimes I + I \otimes H)'\). Since \(A \in \mathcal{L}(\mathcal{H})\), this shows that the right hand sides of these identities belong to

\[
\mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)').
\]

Next, (32) with \(T = q_j \otimes I\) or \(T = p_j \otimes I\) show that these identities hold in the space \(\mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H) \cap \text{Dom}(C), \text{Form-Dom}(H \otimes I + I \otimes H)' + \text{Dom}(C)')\).
Likewise, for \( j = 1, \ldots, d \), one has
\[
(1 \otimes \mathcal{D}_q_j)(C - A \otimes I - I \otimes B) = 2(I \otimes \mathcal{D}_q_j)B - q_j \otimes I) \\
\in \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)', \text{Form-Dom}(H \otimes I + I \otimes H)')(I \otimes \mathcal{D}_p_j)(C - A \otimes I - I \otimes B) = 2(I \otimes \mathcal{D}_p_j)B - p_j \otimes I)
\in \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)').
\]

Let \( \Phi, \Psi \in \text{Ker}(F)^\perp \) be eigenvectors of \( F \). According to (a), one has
\[
\Phi, \Psi \in \text{Dom}(C) \cap \text{Form-Dom}(H \otimes I + I \otimes H),
\]
and
\[
2((\mathcal{D}_q_j, A \otimes I - I \otimes q_j) \Phi, \Psi)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} = \frac{i}{\hbar} ((p_j \otimes I) \Phi(\langle C - A \otimes I - I \otimes B) \Phi(p_j \otimes I) \Psi)_{\mathcal{B}} = 0
\]
for all \( j = 1, \ldots, d \), since \( \Phi, \Psi \in \text{Ker}(C - A \otimes I - I \otimes B) \) by (a). Likewise
\[
2((\mathcal{D}_p_j, A \otimes I - I \otimes p_j) \Phi, \Psi)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} = -\frac{i}{\hbar} ((p_j \otimes I) \Phi(\langle C - A \otimes I - I \otimes B) \Phi(p_j \otimes I) \Psi)_{\mathcal{B}} = 0
\]
for all \( j = 1, \ldots, d \).

Let \( (\Phi_k)_{k \geq 1} \) be a complete orthonormal system of eigenvectors of \( F \) in \( \mathcal{B} \), and let \( \lambda_k \geq 0 \) be defined by \( F \Phi_k = \lambda_k \Phi_k \). Then
\[
F^{1/2} = \sum_{k \geq 1} \lambda_k \| \Phi_k \| \langle \Phi_k, \Phi_k \rangle,
\]
and, for each \( T \in \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)'), \text{Form-Dom}(H \otimes I + I \otimes H) \) and each \( \phi, \psi \in \mathcal{B} \), one has
\[
\sum_{k \geq 1} \frac{\lambda_k \lambda_j}{\lambda_k, \lambda_j > 0} (\langle \Phi_k, \psi \rangle)_{\mathcal{B}} \otimes (\Phi_k, \phi)_{\mathcal{B}} \langle (T \Phi_k, \Phi_t)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} \rangle
\]
\[
= \langle \phi|^1/2 T F^{1/2} | \psi \rangle.
\]
Observe that this last series is absolutely convergent since
\[
\sum_{k \geq 1} \sum_{\lambda_k, \lambda_j > 0} \lambda_k^{1/2} \lambda_j^{1/2} \langle (T \Phi_k, \Phi_t)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} \rangle
\]
\[
\times \langle \Phi_k | \phi \rangle_{\mathcal{B}} \otimes (\Phi_k, \phi)_{\mathcal{B}} \langle (T \Phi_k, \Phi_t)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} \rangle
\]
\[
\leq \| T \| \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)'), \text{Form-Dom}(H \otimes I + I \otimes H) \sum_{\lambda_k, \lambda_j > 0} \lambda_k^{1/2} \lambda_j (\langle (T \Phi_k, \Phi_t)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} \rangle
\]
\[
\leq \| T \| \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)', \text{Form-Dom}(H \otimes I + I \otimes H) \sum_{\lambda_k, \lambda_j > 0} \lambda_k^{1/2} \lambda_j (\langle (T \Phi_k, \Phi_t)_{\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)} \rangle
\]
\[
\leq \| T \| \mathcal{L}(\text{Form-Dom}(H \otimes I + I \otimes H), \text{Form-Dom}(H \otimes I + I \otimes H)' \| \phi \|_{\mathcal{B}} \| \psi \|_{\mathcal{B}}.\]
Hence
\[ \sum_{k,l \geq 0} \lambda_k^{1/2} \lambda_{l,0}^{1/2} \langle T \Phi_k, \Phi_l \rangle_{\text{Form-Dom}(H \otimes I + I \otimes H)} \cdot \text{Form-Dom}(H \otimes I + I \otimes H) \langle \Phi_k, \Phi_l \rangle = F^{1/2} T F^{1/2} \in \mathcal{L}(\mathfrak{h} \otimes \mathfrak{h}) \]
by the Riesz representation theorem. Setting successively
\[
T = \mathcal{P}_{q_j} A \otimes I - I \otimes q_j \quad \text{and} \quad T = \mathcal{P}_{p_j} A \otimes I - I \otimes p_j,
\]
\[
T = I \otimes \mathcal{P}_{q_j} B - q_j \otimes I \quad \text{and} \quad T = I \otimes \mathcal{P}_{p_j} B - p_j \otimes I,
\]
for all \( j = 1, \ldots, d \) in (49) and using (47) and (48) implies statement (b).
\[ \square \]

6. Examples

In this section, we shall study the optimal operators \( a \) and \( b \) from the Kantorovich duality theorem, together with the structure of optimal couplings, on a few elementary examples.

6.1. The case where \( R \) is a rank-one projection. A straightforward consequence of Lemma 4.1 is the following important observation.

**Lemma 6.1.** Assume that \( R \in \mathcal{D}(\mathfrak{h}) \) is a projection. Then \( \text{rank}(R) = 1 \) and for each \( S \in \mathcal{D}(\mathfrak{h}) \), one has
\[
\mathcal{C}(R, S) = \{ R \otimes S \}.
\]

This is the quantum analogue of the case where one considers two Borel probability measures \( \mu \) and \( \nu \), one of which, say \( \mu \), is a Dirac measure. In that case, it is obvious that \( \Pi(\mu, \nu) = \{ \mu \otimes \nu \} \) (all the mass from \( \nu \) is transported to the support of the Dirac measure). Indeed, pure states, corresponding to density operators of the form \( R = | \phi \rangle \langle \phi | \) where \( \phi \) is a normalized element of \( \mathfrak{h} \), are the quantum analogues of phase space points in classical mechanics.

**Proof.** We recall that, if \( R \) is an orthogonal projection, one has \( \text{rank}(R) = \text{trace}(R) \). On the other hand \( \text{trace}(R) = 1 \) since \( R \in \mathcal{D}(\mathfrak{h}) \). Denoting by \( \Omega \) the orthogonal projection on \( \text{Ker}(S)^4 \), Lemma 4.1 implies that
\[
(R \otimes I) F(R \otimes I) = (R \otimes I)(R \otimes \Omega) F(R \otimes \Omega)(R \otimes I) = (R^2 \otimes \Omega) F(R^2 \otimes \Omega) = (R \otimes \Omega) F(R \otimes \Omega) = F.
\]
Thus, for each \( \phi_1, \phi_2, \psi_1, \psi_2 \in \mathfrak{h} \), one has
\[
\langle \phi_1 \otimes \psi_1 | F | \phi_2 \otimes \psi_2 \rangle = \langle \phi_1 \otimes \psi_1 | (R \otimes I) F(R \otimes I) | \phi_2 \otimes \psi_2 \rangle = \langle \phi_1 | e \rangle \langle e \otimes \psi_1 | F | e \otimes \psi_2 \rangle = \langle \phi_1 | R | \phi_2 \rangle \langle \psi_1 | G | \psi_2 \rangle,
\]
where \( \| e \|_{\mathfrak{h}} = 1 \) and \( Ce = \text{ran}(R) \), while \( G \) is the self-adjoint operator on \( \mathfrak{h} \) such that
\[
\langle \psi_1 | G | \psi_2 \rangle = \langle e \otimes \psi_1 | F | e \otimes \psi_2 \rangle, \quad \psi_1, \psi_2 \in \mathfrak{h}.
\]
(The existence and uniqueness of \( G \) follows from the Riesz representation theorem.)

Hence \( F = R \otimes G \), and since \( F \in \mathcal{C}(R, S) \),
\[
\text{trace}(R \otimes G)(I \otimes B) = \text{trace}(GB) = \text{trace}(SB)
\]
for each finite rank \( B \in \mathcal{L}(\mathfrak{h}) \), which implies that \( G = S \).  \( \square \)
Let $R$ be a rank-one projection, and let $S$ be a finite-rank density operator on the Hilbert space $\mathcal{H}$. Write
\[
R := |\phi\rangle\langle\phi|, \quad S := \sum_{j=1}^{n} \sigma_j |\psi_j\rangle\langle\psi_j|,
\]
where $(\psi_j)_{1 \leq j \leq n}$ is an orthonormal system in $\mathcal{H}$, while
\[
\sigma_j > 0 \text{ for } j = 1, \ldots, n, \quad \text{and} \quad \sum_{j=1}^{n} \sigma_j = 1.
\]
By Theorem 2.4, the optimal operators $a$ and $b$ should be sought in the form
\[
a := \alpha |\phi\rangle\langle\phi|, \quad b := \sum_{k=1}^{n} \beta_k |e_k\rangle\langle e_k|,
\]
where $(e_k)_{1 \leq k \leq n}$ is an appropriate orthonormal basis of
\[
\text{span}\{\psi_1, \ldots, \psi_n\} = \mathcal{J}_0[S] = \mathcal{J}[S],
\]
which remains to be determined. Then $F = R \otimes S$, and elementary computations show that
\[
\text{trace}(F^{1/2}CF^{1/2}) = \sum_{j=1}^{n} \sigma_j \langle \phi \otimes \psi_j | C | \phi \otimes \psi_j \rangle,
\]
together with
\[
\text{trace}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}) = \alpha + \sum_{j,k=1}^{n} \sigma_j \beta_k |\langle \psi_j | e_k \rangle|^2.
\]
Since the sesquilinear form
\[
\psi, \psi' \mapsto \langle \phi \otimes \psi | C - a \otimes I - I \otimes b | \phi \otimes \psi' \rangle
\]
is nonnegative on $\mathcal{J}_0[S] = \mathcal{J}[S]$, the optimality condition in Theorem 2.5 can be expressed on any basis of $\mathcal{J}_0[S] = \mathcal{J}[S]$. For instance, it can be expressed in terms of the orthonormal system $(e_k)_{1 \leq k \leq n}$ of eigenvectors of $b$ (still undetermined at this point). This gives the condition
\[
\langle \phi \otimes e_k | C | \phi \otimes e_l \rangle = \alpha \delta_{kl} + \beta_k \delta_{kl}, \quad k, l = 1, \ldots, n.
\]
In other words, the orthonormal system $(e_k)_{1 \leq k \leq n}$ is orthogonal for the sesquilinear form $\psi, \psi' \mapsto \langle \phi \otimes \psi | C | \phi \otimes \psi' \rangle$ defined on $\text{span}\{\psi_j, 1 \leq j \leq n\}$. This determines the orthonormal system $(e_k)_{1 \leq k \leq n}$ to some extent.

More precisely, pick any orthonormal system $(e_k)_{1 \leq k \leq n}$ which is orthogonal for the sesquilinear form above, and choose $b$ so that $(e_k)_{1 \leq k \leq n}$ is a basis of eigenvectors of $b$ in $\mathcal{J}_0[S] = \mathcal{J}[S]$. With this choice of $(e_k)_{1 \leq k \leq n}$, one has
\[
\langle \phi \otimes \psi_j | C | \phi \otimes \psi_j \rangle = \sum_{k,l=1}^{n} \langle \phi \otimes e_k | C | \phi \otimes e_l \rangle \langle \psi_j | e_k \rangle \overline{\langle \psi_j | e_l \rangle} = \sum_{k=1}^{n} (\alpha + \beta_k) |\langle \psi_j | e_k \rangle|^2 = \alpha + \sum_{k=1}^{n} \beta_k |\langle \psi_j | e_k \rangle|^2.
\]
Thus
\[
\text{trace}(F^{1/2}CF^{1/2}) = \sum_{j=1}^{n} \sigma_j \langle \phi \otimes \psi_j |C| \phi \otimes \psi_j \rangle = \sum_{j=1}^{n} \sigma_j \left( \alpha + \sum_{k=1}^{n} \beta_k |\langle \psi_j | e_k \rangle|^2 \right)
\]
\[
= \alpha + \sum_{j,k=1}^{n} \sigma_j \beta_k |\langle \psi_j | e_k \rangle|^2 = \text{trace}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}) .
\]

6.2. The case where \( R = S \) is a Töplitz operator. Another easy example is the case where \( R = S \) are both Töplitz density operators. Let \( \mu \) be a Radon measure on \( \mathbb{R}^d \times \mathbb{R}^d \); the (possibly unbounded) Töplitz operator with symbol \( \mu \) is defined by duality by the formula
\[
(u | \mathcal{P}^T_h[\mu] | v) := \frac{1}{(2\pi \hbar)^d} \int_{\mathbb{R}^d \times \mathbb{R}^d} \langle u | q, p \rangle \langle q, p | v \rangle \mu(dqdp) ,
\]
for all \( u, v \in L^2(\mathbb{R}^d) \) such that the functions \( \langle q, p \rangle \mapsto \langle u | q, p \rangle \) and \( \langle q, p \rangle \mapsto \langle v | q, p \rangle \) both belong to \( L^2(\mathbb{R}^d \times \mathbb{R}^d, \mu) \), where
\[
|q, p\rangle := (\pi \hbar)^{-d/4} e^{-|q|^2/2\hbar} e^{ipx/\hbar} .
\]

We recall that
\[
\mu \in \mathcal{P}_2(\mathbb{R}^d \times \mathbb{R}^d) \implies \mathcal{P}^T_h[\mu] \in \mathcal{D}_2(\mathbb{F}) ,
\]
(see [13], Theorem 2.2 (iii), and that
\[
MK_h(\mathcal{P}^T_h[\mu], \mathcal{P}^T_h[\nu])^2 \leq \text{dist}_{MK,2}(\mu, \nu)^2 + 2dh
\]
for all \( \mu, \nu \in \mathcal{P}_2(\mathbb{R}^d \times \mathbb{R}^d) \) (see [13], Theorem 2.2 (iii), or Theorem 2.3 (1) in [11]), while
\[
2dh \leq MK_h(R, S)^2 \quad \text{for all } R, S \in \mathcal{D}_2(\mathbb{F}) ,
\]
according to fla. (14) in [11].

Hence
\[
MK_h(\mathcal{P}^T_h[\mu], \mathcal{P}^T_h[\mu])^2 = 2dh .
\]
This is Corollary 2.4 in [13].

An optimal element of \( \mathcal{C}(\mathcal{P}^T_h[\mu], \mathcal{P}^T_h[\mu]) \) is
\[
F := \int_{\mathbb{R}^d \times \mathbb{R}^d} |q, p\rangle \langle q, p|^2 \mu(dqdp) .
\]
That \( F \in \mathcal{C}(\mathcal{P}^T_h[\mu], \mathcal{P}^T_h[\mu]) \) follows from Lemma 4.1 in [11]. This is the analogue of the diagonal coupling \( \text{diag} \# \mu \) of one Borel probability measure \( \mu \) with itself, where \( \text{diag} \) is the diagonal embedding \( x \mapsto (x, x) \). (Informally, the diagonal coupling is \( \mu(dx)\delta(y-x) \).

Moreover
\[
\text{trace}(F^{1/2}CF^{1/2}) = \sup_{\epsilon > 0} \text{trace}(F(I + \epsilon C)^{-1}C)
\]
\[
= \int_{\mathbb{R}^d \times \mathbb{R}^d} \langle q, p, \mu \rangle (C|q, p | p \rangle \mu(dqdp) = 2dh .
\]
as explained in the proof of Lemma 2.1 of [13]. In the formula above, we have denoted
\[
|q_1, q_2, p_1, p_2\rangle = |q_1, p_1\rangle \otimes |q_2, p_2\rangle , \quad \langle q_1, q_2, p_1, p_2 \rangle = \langle q_1, p_1\rangle \otimes \langle q_2, p_2 \rangle
\]
We claim that one can choose in this case
\[
a = b = dh I_\mathbb{F} .
\]
Indeed, according to the Heisenberg uncertainty principle
\[ C \geq 2\hbar I \otimes I = a \otimes I + I \otimes a. \]

On the other hand
\[
\text{trace}(a \OP_h^T[\mu]) = dh \text{trace}(\OP_h^T[\mu])
= dh \int_{R^d \times R^d} \mu(dx d\xi) = dh,
\]
so that, with the choice of \( a \) and \( b \) above, one has
\[
\text{trace}(a \OP_h^T[\mu]) + \text{trace}(b \OP_h^T[\mu]) = 2dh = \text{trace}(F^{1/2}CF^{1/2}).
\]

6.3. When is the optimal coupling a Töplitz operator? Let \( R \) and \( S \) be Töplitz density operators, of the form \( R = \OP_h^T[(2\pi \hbar)^d \mu] \) and \( S = \OP_h^T[(2\pi \hbar)^d \nu] \) with \( \mu, \nu \in \mathcal{P}_2(R^d \times R^d) \). When is an optimal coupling of \( R \) and \( S \) a Töplitz operator, of the form \( F = \OP_h^T[(2\pi \hbar)^d \lambda] \) for some \( \lambda \in \mathcal{P}(R^d \times R^d \times R^d \times R^d) \)?

We shall see that this question is answered in the affirmative only under rather stringent conditions.

We already know the answer in two different cases discussed above:
(a) \( R = S \) (see previous section);
(b) \( \mu = \delta_{q,p} \) and \( \nu = \delta_{q',p'} \), in which case \( R \) and \( S \) are rank-one operators, in which case the only (and therefore the optimal) coupling is
\[
R \otimes S = \OP_h^T[(2\pi \hbar)^d \mu \otimes \nu].
\]

In the analysis below, consider this problem when \( \mu \) and \( \nu \) are of the form
\[
\mu(dqdp) = m(q, p)dqdp, \quad \nu(dqdp) = n(q, p)dqdp, \quad m, n > 0 \text{ a.e.}
\]
(The case (b) mentioned above obviously fails to satisfy this assumption.)

This assumption clearly implies that \( \ker(R) = \ker(S) = \{0\} \). To see this, we first recall one definition of the Husimi transform of an operator \( A \) on \( L^2(R^d) \):
\[
\hat{W}_h[A](q, p) := \frac{1}{(2\pi \hbar)^d} \langle q, p | A | q, p \rangle, \quad q, p \in R^d.
\]
(There is another, equivalent definition in terms of the Wigner transform: see (49), and the formula following (53) in [11]; the equivalence between these two definitions is the formula before (54) in [11].) Now, if \( \phi \in \ker(R) \), one has, by formula (54) in [11],
\[
\langle \phi | R | \phi \rangle = \text{trace}(|\phi \rangle \langle \phi | R) = \int_{R^d} \hat{W}_h[|\phi \rangle \langle \phi |](q, p)m(q, p)dqdp = 0.
\]
This implies that \( \hat{W}_h[|\phi \rangle \langle \phi |] = 0 \), which implies in turn that \( \phi = 0 \). For this implication, see for instance Remark 2.3 in [12]. Equivalently, using (46) and (54) in [11] with \( R = |\phi \rangle \langle \phi | \) shows that
\[
\|\phi\|_{\hat{h}}^2 = \text{trace}(|\phi \rangle \langle \phi |) = \int_{R^d} \hat{W}_h[|\phi \rangle \langle \phi |](q, p)dqdp = 0.
\]
Let \( (a, b) \in \hat{R}(R, S) \) such that
\[
\text{trace}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}) = MK_h(R, S)^2.
\]
Assume that \( (q, p) \in \mathcal{J}[R] \cap \mathcal{J}[S] \) for each \( (q, p) \in R^d \times R^d \), and that the functions
\[
(q, p) \mapsto q, p \quad \text{ and } \quad (q, p) \mapsto q, p
\]
are of class $C^2$ on $\mathbb{R}^d \times \mathbb{R}^d$. Define
\[ a(q, p) := \tilde{W}_h[a](q, p), \quad b(q, p) := \tilde{W}_h[b](q, p), \]
and
\[ \hat{a}(q, p) := \frac{1}{2}(|q|^2 + |p|^2 - a(q, p) + dh), \quad \hat{b}(q, p) := \frac{1}{2}(|q|^2 + |p|^2 - b(q, p) + dh). \]
Notice that $a \in L^1(\mathbb{R}^{2d}, \mu)$ and $b \in L^1(\mathbb{R}^{2d}, \nu)$ since $R^{1/2}aR^{1/2}$ and $S^{1/2}bS^{1/2}$ belong to $L^1(S)$ by definition of $\hat{R}(R, S)$, because $\text{Ker}(R) = \text{Ker}(S) = \{0\}$.

**Theorem 6.2.** The following conditions are equivalent:
(a) there exists $\lambda \in \mathcal{P}(\mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d)$ such that $F = \text{OP}_h^T[(2\pi h)^d \lambda]$ is an optimal coupling of $R$ and $S$, i.e.
\[ F \in \mathcal{C}(R, S) \text{ and } \text{trace}(F^{1/2}CF^{1/2}) = MK_h(R, S)^2; \]
(b) one has
\[ MK_h(R, S)^2 = \text{dist}_{MK,2}(\mu, \nu)^2 + 2dh; \]
(c) the functions $\hat{a}$ and $\hat{b}$ are the Legendre transforms of each other, i.e.
\[ \hat{a}^* = \hat{b} \quad \text{and} \quad \hat{b}^* = \hat{a}, \]
and satisfy the Monge-Ampère equation
\[ \det(\nabla^2 \hat{a}) = \frac{m}{n \circ \nabla \hat{a}}. \]

If these conditions are satisfied, $\lambda$ is of the form
\[ \lambda(dq_1dp_1dq_2dp_2) = m(q_1, p_1)\delta((q_2, p_2) - \nabla \hat{a}(q_1, p_1))dq_1dp_1. \]

Let us recall that, for two Töplitz densities $R$ and $S$ in $D_2(L^2(\mathbb{R}^d))$ with symbols $(2\pi h)^d \mu$ and $(2\pi h)^d \nu$ resp., it has been proved in [11] (Theorem 2.3 (1)) that
\[ MK_h(R, S)^2 \leq \text{dist}_{MK,2}(\mu, \nu)^2 + 2dh. \]
We also recall the example constructed in section 3 of [7], where $\mu$ and $\nu$ are convex combinations of two Dirac measures with identical supports, for which the inequality above is strict. This example explains the title of [7]: quantum optimal transport is “cheaper” that classical optimal transport, due to additional degrees of freedom in quantum couplings which have no classical interpretation: see the penultimate paragraph on pp. 161–162 in [7].

At variance with the example in section 3 of [7], the situation where the optimal coupling between two Töplitz densities $R, S$ is a Töplitz operator is the closest to the classical setting. The classical optimal transport map between the symbols of $R$ and $S$ is transformed into an optimal quantum coupling by Töplitz quantization. There are no strictly quantum effects in this coupling, unlike in the case discussed in section 3 of [7], so that, the inequality in Theorem 2.3 (1) of [11] becomes an equality in this case. In other words, apart from the additional term $2dh$, the quantum distance between such Töplitz densities is indeed the classical Monge-Kantorovich distance between their symbols. Examples of Töplitz densities satisfying properties (a) and (b) of the theorem above can be found in section 2 of [7]. However, the example constructed in section 2 of [7] does not fall exactly in the class of densities considered in the theorem above, since the symbols of the densities considered in section 2 of [7] are convex combinations of two Dirac measures (with different supports and equal coefficients).
Proof. Assume that (a) holds. One has
\begin{equation}
\text{trace}(F^{1/2} CF^{1/2}) = \int_{\mathbb{R}^{2d}} \tilde{W}_h[C](q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2)
\end{equation}
and
\[ \tilde{W}_h[C](q_1, p_1, q_2, p_2) = c(q_1, p_1, q_2, p_2) + 2dh \]
with
\[ c(q_1, p_1, q_2, p_2) = |q_1 - q_2|^2 + |p_1 - p_2|^2. \]
Let us take (53) for granted — we shall give a quick proof of this formula at the end of the present section.

Since \( F \in \mathcal{C}(R, S) \), the symbol \((2\pi h)^{2d} \lambda \) of \( F \) satisfies \( \lambda \in \Pi(\mu, \nu) \), the set of couplings of \( \mu \) and \( \nu \), according to Lemma 4.1 in [11]. Hence
\[ MK_h(R, S)^2 = \int_{\mathbb{R}^{2d}} c(q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2) + 2dh \geq \text{dist}_{MK,2}(\mu, \nu)^2 + 2dh \]
By Theorem 2.3 (1) of [11], one has
\[ MK_h(R, S)^2 \leq \text{dist}_{MK,2}(\mu, \nu)^2 + 2dh, \]
which proves (b).

Conversely, pick an optimal coupling \( \lambda \in \Pi(\mu, \nu) \) and set \( F = \text{OP}_h^T[(2\pi h)^{2d} \lambda] \). Then \( F \in \mathcal{C}(R, S) \) by Lemma 4.1 in [11], and
\[ \text{dist}_{MK,2}(\mu, \nu)^2 + 2dh = \int_{\mathbb{R}^{2d}} c(q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2) + 2dh = \text{trace}(F^{1/2} CF^{1/2}). \]
Hence, (b) implies that
\[ MK_h(R, S)^2 = \text{trace}(F^{1/2} CF^{1/2}), \]
so that (a) holds.

If (a) holds, then
\[ \int_{\mathbb{R}^{2d}} c(q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2) + 2dh = \text{trace}(F^{1/2} CF^{1/2}) = \text{trace}(R^{1/2} a R^{1/2} + S^{1/2} b S^{1/2}), \]
On the other hand, since \( (a, b) \in \tilde{\mathcal{R}}(R, S) \), and since \( (q_1, p) \in \mathcal{J}[R] \cap \mathcal{J}[S] \), one has
\[ c(q_1, p_1, p_2)[C]q_1, q_2, p_1, p_2] \geq (q_1, p_1)a(q_1, p_1) + (q_2, p_2)b(q_2, p_2) \]
i.e.
\[ c(q_1, q_2, p_2) \geq (q_1, p_1) - dh + b(q_2, p_2) - dh. \]
Since \( a \in L^1(\mathbb{R}^{2d}, \mu) \) and \( b \in L^1(\mathbb{R}^{2d}, \nu) \) and \( \lambda \in \Pi(\mu, \nu) \) with
\[ \int_{\mathbb{R}^{2d}} c(q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2) = \int_{\mathbb{R}^{2d}} (a(q_1, p_1) - dh) \mu(dq_1 dp_1) \\
+ \int_{\mathbb{R}^{2d}} (b(q_2, p_2) - dh) \nu(dq_2 dp_2), \]
we conclude from Theorem 1.3 in [23] (the Kantorovich duality theorem) that \( \lambda \) is an optimal element of \( \Pi(\mu, \nu) \), and that the optimal functions \( a \) and \( b \) are Legendre duals of each other (see Lemma 2.10 in [23]).

By the Brenier theorem (Theorem 2.12 (ii) in [23], the measure \( \lambda \) is of the form
\[ \lambda(dq_1 dp_1 dq_2 dp_2) = m(q_1, p_1)\delta((q_2, p_2) - \nabla \Phi(q_1, p_1))dq_1 dp_1, \]
with \( \Phi \) convex. Hence
\[
\tilde{a}(q_1,p_1) + \tilde{b}(\nabla \Phi(q_1,p_1)) = q_1 \cdot \nabla_q \Phi(q_1,p_1) + p_1 \cdot \nabla_p \Phi(q_1,p_1) \quad \text{for a.e.} \quad (q_1,p_1).
\]
On the other hand, we know that
\[
\tilde{a}(z,\zeta) + \tilde{b}(\nabla \Phi(q_1,p_1)) \geq z \cdot \nabla_q \Phi(q_1,p_1) + \zeta \cdot \nabla_p \Phi(q_1,p_1) \quad \text{for a.e.} \quad (q_1,p_1,z,\zeta).
\]
Therefore
\[
\tilde{a}(z,\zeta) - a(q_1,p_1) \geq (z-q_1) \cdot \nabla_q \Phi(q_1,p_1) + (\zeta-p_1) \cdot \nabla_p \Phi(q_1,p_1) \quad \text{for a.e.} \quad (q_1,p_1,z,\zeta).
\]
Hence \( \nabla \Phi = \nabla \tilde{a} \), and since \( \nabla \Phi \# \mu = \nu \), the change of variables formula implies that
\[
\det(\nabla^2 \Phi) \circ \nabla \Phi = m.
\]
This proves (c).

Conversely, assume that (c) holds and set
\[
\lambda(dq_1dp_1dq_2dp_2) = m(q_1,p_1)\delta((q_2,p_2) - \nabla \tilde{a}(q_1,p_1))dq_1dp_1.
\]
Obviously, \( \lambda \in \Pi(\mu,\nu) \) because of the Monge-Ampère equation satisfied by \( \tilde{a} \), and Brenier’s theorem implies that
\[
\int_{\mathbb{R}^{2d}} c(q_1,p_1,q_2,p_2)\lambda(dq_1dp_1dq_2dp_2) = \text{dist}_{MK;2}(\mu,\nu)^2.
\]
Set \( F = \text{OP}_h^T((2\pi h)^2\lambda) \); by Lemma 4.1 in [11], one has \( F \in \mathcal{C}(R,S) \). On the other hand, since \( \tilde{a}^* = \tilde{b} \) and \( \tilde{b}^* = \tilde{a} \), one has
\[
\tilde{a}(q_1,p_1) + \tilde{b}(q_2,p_2) = q_1 \cdot q_2 + p_1 \cdot p_2 \quad \lambda - \text{a.e. in} \quad (q_1,p_1,q_2,p_2)
\]
or equivalently
\[
\int_{\mathbb{R}^{2d}} c(q_1,p_1,q_2,p_2)\lambda(dq_1dp_1dq_2dp_2) + 2dh = \int_{\mathbb{R}^{2d}} a(q_1,p_1)\mu(dq_1dp_1)
\]
\[
+ \int_{\mathbb{R}^{2d}} b(q_2,p_2)\nu(dq_2dp_2).
\]
Since \( a = \hat{W}_h[a] \) and \( b = \hat{W}_h[b] \), this equality can be recast as
\[
\text{trace}(F^{1/2}CF^{1/2}) = \text{trace}(R^{1/2}aR^{1/2} + S^{1/2}bS^{1/2}) = MK_h(R,S)^2,
\]
so that \( F \) is an optimal element of \( \mathcal{C}(R,S) \), and (a) holds.

**Proof of (53).** Let \((e_j)_{j \geq 1}\) be a complete orthonormal system of eigenvectors of \( F \in \mathcal{D}_2(\mathcal{H} \otimes \mathcal{H}) \), so that
\[
F = \sum_{j \geq 1} \ell_j |e_j\rangle\langle e_j|, \quad \text{with} \quad \sum_{j \geq 1} \ell_j = 1 \quad \text{and} \quad \ell_j \geq 0 \quad \text{for all} \quad j \geq 1.
\]
On the other hand, by formula (48) in [11]
\[
\text{OP}_h^T[c] = C + \frac{1}{2} h(\Delta_{q_1,p_1,q_2,p_2}c)I_{\mathcal{H} \otimes \mathcal{H}} = C + 4dhI,
\]
where we recall that
\[
c(q_1,p_1,q_2,p_2) = |q_1 - q_2|^2 + |p_1 - p_2|^2.
\]
By Tonelli’s theorem, denoting \( z_1 := (q_1, p_1) \) and \( z_2 := (q_2, p_2) \), one has

\[
\text{trace}(F^{1/2}CF^{1/2}) + 4\hbar = \sum_{j,k \geq 1} \frac{e^{i\hbar^2 \frac{j^2}{4\hbar^2} + i\hbar^2 \frac{k^2}{4\hbar^2}}}{(2\pi\hbar)^2} \int_{\mathbb{R}^{4d}} (e_j[z_1, z_2]) (e_k[z_1, z_2]) (e_j[z_1, z_2]) (e_k[z_1, z_2]) dq_1 dp_1 dq_2 dp_2
\]

\[
= \sum_{j \geq 1} \frac{e^{i\hbar^2 \frac{j^2}{4\hbar^2}}}{(2\pi\hbar)^2} \int_{\mathbb{R}^{4d}} (e_j[z_1, z_2]) (e_j[z_1, z_2]) (e_j[z_1, z_2]) (e_j[z_1, z_2]) dq_1 dp_1 dq_2 dp_2
\]

\[
= \int_{\mathbb{R}^{4d}} \tilde{W}[F](z_1, z_2) c(z_1, z_2) dq_1 dp_1 dq_2 dp_2.
\]

Since \( F = \text{OP}_h^\top[(2\pi\hbar)^2 \lambda] \), one has \( \tilde{W}_h[F] = e^{\frac{i}{\hbar^2} \Delta_{q_1, q_2, p_1, p_2} \lambda} \) (see (51) and the formula following (53) in [11]), so that

\[
\text{trace}(F^{1/2}CF^{1/2}) + 4\hbar = \int_{\mathbb{R}^{4d}} \tilde{W}[F](z_1, z_2) c(z_1, z_2) dq_1 dp_1 dq_2 dp_2
\]

\[
= \int_{\mathbb{R}^{4d}} e^{\frac{i}{\hbar^2} \Delta_{q_1, q_2, p_1, p_2} \lambda} (c(q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2)
\]

since \( e^{\frac{i}{\hbar^2} \Delta_{q_1, q_2, p_1, p_2}} \) is self-adjoint. On the other hand

\[
e^{\frac{i}{\hbar^2} \Delta_{q_1, q_2, p_1, p_2} \lambda} (c(q_1, p_1, q_2, p_2) \lambda(dq_1 dp_1 dq_2 dp_2)
\]

so that

\[
\text{trace}(F^{1/2}CF^{1/2}) + 4\hbar = \int_{\mathbb{R}^{4d}} (c(q_1, p_1, q_2, p_2) + 4\hbar) \lambda(dq_1 dp_1 dq_2 dp_2),
\]

which is equivalent to (53).

\[\Box\]

**Appendix A. The Quantum Transport Cost**

The quantum cost is the differential operator

\[
C := \sum_{j=1}^d \left[ (x_j - y_j) - \hbar^2 (\partial x_j - \partial y_j)^2 \right].
\]

For each \( f \equiv f(x_1, y_1, \ldots, x_d, y_d) \in \mathcal{S}(\mathbb{R}^{2d}) \), one has

\[
C f(x_1, y_1, \ldots, x_d, y_d) = \sum_{j=1}^d (Y_j^2 - 4\hbar^2 \partial_{Y_j}^2) f(X_1 + \frac{1}{4} Y_1, X_1 - \frac{1}{4} Y_1, \ldots, X_d + \frac{1}{4} Y_d, X_d - \frac{1}{4} Y_d).
\]

The \( d \) operators \( Y_j^2 - 4\hbar^2 \partial_{Y_j}^2 \) obviously commute pairwise. Since each one of these operators is the quantum Hamiltonian of a harmonic oscillator, we know that a complete orthonormal system of eigenfunctions for \( Y_j^2 - 4\hbar^2 \partial_{Y_j}^2 \) on \( L^2(\mathbb{R}) \) is

\[
(2\hbar)^{-1/4} h_n(Y_j/\sqrt{2\hbar}), \quad n \geq 0,
\]

where \( h_n \) is the \( n \)-th Hermite function

\[
h_n(z) := \pi^{-1/4} (2^n n!)^{-1/2} e^{-z^2/2} H_n(z), \quad H_n(z) := (-1)^n e^{z^2} (e^{-z^2})^{(n)},
\]

\[
h_n(Y_j) := (\pi \hbar)^{-1/4} (2^n n!)^{-1/2} e^{-Y_j^2/4\hbar} H_n(Y_j/\sqrt{2\hbar}), \quad n \geq 0,
\]
with
\[(Y_f^2 - 4h^2 \partial_x^2) h_n(Y_f/\sqrt{2h}) = 2h(2n + 1) h_n(Y_f/\sqrt{2h}), \quad n \geq 0.\]

Since the linear transformation of \(\mathbb{R}^{2d}\)
\[(X_1, Y_1, \ldots, X_d, Y_d) \rightarrow (X_1 + \frac{4}{2} Y_1, X_1 - \frac{4}{2} Y_1, \ldots, X_d + \frac{4}{2} Y_d, X_d - \frac{4}{2} Y_d)\]
has Jacobian determinant \((-1)^d\), it leaves the Lebesgue measure of \(\mathbb{R}^{2d}\) invariant, so that
\[
\Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d}(x_1, y_1, \ldots, x_d, y_d) := (2h)^{-d/2} \prod_{j=1}^{d} h_{m_j}(\frac{x_j + y_j}{2\sqrt{2h}}) h_{n_j}(\frac{x_j - y_j}{2\sqrt{2h}})
\]
defines a complete orthonormal system of eigenfunctions of \(C\), i.e.
\[
\int_{\mathbb{R}^{2d}} \overline{\Psi}_{m_1', \ldots, m_d', n_1', \ldots, n_d'} \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} (x_1, y_1, \ldots, x_d, y_d) dx_1 \ldots dy_d = \prod_{j=1}^{d} \delta_{m_j', m_j} \delta_{n_j', n_j},
\]
with
\[
C \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d}(x_1, y_1, \ldots, x_d, y_d) = 2h(2(n_1 + \ldots + n_d) + d) \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d}(x_1, y_1, \ldots, x_d, y_d).
\]
Thus
\[
C = 2h \sum_{m_1, \ldots, m_d \geq 0} (2(n_1 + \ldots + n_d) + d) \langle \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} \mid \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} \rangle;
\]
in other words, \(C\) has the spectral decomposition
\[
E(d\lambda) = \sum_{m_1, \ldots, m_d \geq 0} \delta(\lambda - 2h(2(n_1 + \ldots + n_d) + d)) \langle \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} \mid \Psi_{m_1, \ldots, m_d, n_1, \ldots, n_d} \rangle.
\]

**APPENDIX B. MONOTONE CONVERGENCE FOR TRACE-CLASS OPERATORS**

We recall the analogue of the Beppo Levi monotone convergence theorem for operators in the form convenient for our purpose.

Let \(\mathcal{H}\) be a separable Hilbert space and \(0 \leq T = T^* \in \mathcal{L}(\mathcal{H})\). For each complete orthonormal system \((e_j)_{j \geq 1}\) of \(\mathcal{H}\), set
\[
\text{trace}_\mathcal{H}(T) = \|T\|_1 := \sum_{j \geq 1} \langle e_j \mid T e_j \rangle \in [0, +\infty].
\]
See Theorem 2.14 in [22]; in particular the expression on the last right hand side of these equalities is independent of the complete orthonormal system \((e_j)_{j \geq 1}\). Then
\[
T \in \mathcal{L}^1(\mathcal{H}) \iff \|T\|_1 < \infty.
\]

**Lemma B.1** (Monotone convergence). Consider a sequence \(T_n = T_n^* \in \mathcal{L}(\mathcal{H})\) such that
\[(i) \quad 0 \leq T_1 \leq T_2 \leq \ldots \leq T_n \leq \ldots, \quad \text{and} \sup_{n \geq 1} \text{sup} \langle x \mid T_n x \rangle < +\infty \text{ for all } x \in \mathcal{H},\]
or
\[(ii) \quad 0 \leq T_1 \leq T_2 \leq \ldots \leq T_n \leq \ldots, \quad \text{and} \sup_{n \geq 1} \text{trace}_\mathcal{H}(T_n) < +\infty.\]

Then
\[(a) \text{ there exists } T = T^* \in \mathcal{L}(\mathcal{H}) \text{ such that } T \geq 0 \text{ and } T_n \rightarrow T \text{ weakly as } n \rightarrow \infty, \text{ and}\]
\[(b) \text{ trace}_\mathcal{H}(T_n) \rightarrow \text{ trace}_\mathcal{H}(T) \text{ as } n \rightarrow \infty.\]
Thus, assumption (ii) implies (i), which implies in turn (a) and (b).

Since the sequence \( \langle x|T_n|x \rangle \in [0, +\infty) \) is nondecreasing for each \( x \in \mathcal{H} \),
\[
\langle x|T_n|x \rangle \rightarrow \sup_{n \geq 1} \langle x|T_n|x \rangle =: q(x) \in [0, +\infty) \quad \text{for all } x \in \mathcal{H}
\]
as \( n \rightarrow \infty \). Hence
\[
\langle x|T_n|y \rangle = \langle y|T_n|x \rangle \rightarrow \frac{1}{2}(q(x+y) - q(x-y) + iq(x-iy) - iq(x+iy)) =: b(x, y) \in \mathbb{C}
\]
as \( n \rightarrow +\infty \). By construction, \( b \) is a nonnegative sesquilinear form on \( \mathcal{H} \).

Consider, for each \( k \geq 0 \),
\[
F_k := \{ x \in \mathcal{H} \text{ s.t. } \langle x|T_n|x \rangle \leq k \text{ for each } n \geq 1 \}.
\]
The set \( F_k \) is closed for each \( k \geq 0 \), being the intersection of the closed sets defined by the inequality \( \langle x|T_n|x \rangle \leq k \) as \( n \geq 1 \). Since the sequence \( \langle x|T_n|x \rangle \) is bounded for each \( x \in \mathcal{H} \),
\[
\bigcup_{k \geq 0} F_k = \mathcal{H}.
\]

Applying Baire’s theorem shows that there exists \( N \geq 0 \) such that \( \hat{F}_N \neq \emptyset \). In other words, there exists \( r > 0 \) and \( x_0 \in \mathcal{H} \) such that
\[
|x - x_0| \leq r \implies \langle x|T_n|x \rangle \leq N \text{ for all } n \geq 1.
\]
By linearity and positivity of \( T_n \), this implies
\[
\langle |z|T_n|z \rangle \leq \frac{2}{r}(M + N)||z||^2 \text{ for all } n \geq 1, \quad \text{with } M := \sup_{n \geq 1} \langle x_0|T_n|x_0 \rangle.
\]
In particular
\[
\sup_{|z| \leq 1} q(z) \leq \frac{2}{r}(M + N), \quad \text{so that } |b(x, y)| \leq \frac{2}{r}(M + N)||x||\mathcal{H}||y||\mathcal{H}
\]
for each \( x, y \in \mathcal{H} \) by the Cauchy-Schwarz inequality. By the Riesz representation theorem, there exists \( T \in \mathcal{L}(\mathcal{H}) \) such that
\[
T = T^* \geq 0, \quad \text{and } b(x, y) = \langle x|T|y \rangle.
\]
This proves (a). Observe that \( T \geq T_n \) for each \( n \geq 1 \), so that
\[
\sup_{n \geq 1} \text{trace}_{\mathcal{H}}(T_n) \leq \text{trace}_{\mathcal{H}}(T).
\]
In particular
\[
\sup_{n \geq 1} \text{trace}_{\mathcal{H}}(T_n) = +\infty \implies \text{trace}_{\mathcal{H}}(T) = +\infty.
\]
Since the sequence \( \text{trace}_{\mathcal{H}}(T_n) \) is nondecreasing,
\[
\text{trace}_{\mathcal{H}}(T_n) \rightarrow \sup_{n \geq 1} \text{trace}_{\mathcal{H}}(T_n) \quad \text{as } n \rightarrow \infty.
\]
By the noncommutative variant of Fatou’s lemma (Theorem 2.7 (d) in [22]),
\[
\sup_{n \geq 1} \text{trace}_{\mathcal{H}}(T_n) < \infty \implies T \in \mathcal{L}^1(\mathcal{H}) \text{ and } \text{trace}_{\mathcal{H}}(T) \leq \sup_{n \geq 1} \text{trace}_{\mathcal{H}}(T_n).
\]
Since the opposite inequality is already known to hold, this proves (b).

Next we prove (a) and (b) under assumption (ii). Since any \( x \in \mathcal{H} \setminus \{0\} \) can be normalized and completed into a complete orthonormal system of \( \mathcal{H} \), one has
\[
\sup_{n \geq 1} \langle x|T|x \rangle \leq ||x||^2 \sup_{n \geq 1} \text{trace}_{\mathcal{H}}(T_n) < \infty.
\]
Thus, assumption (ii) implies (i), which implies in turn (a) and (b). \qed
Appendix C. The Finite Energy Condition

Let $A = A^*$ be an unbounded self-adjoint operator on $\mathcal{H}$ with domain $\text{Dom}(A)$, and let $E$ be its spectral decomposition.

Throughout this section, we assume that $T \in \mathcal{L}^1(\mathcal{H})$ satisfies $T = T^* \geq 0$, and let $(e_j)_{j \geq 1}$ be a complete orthonormal system of eigenvectors of $T$ with $T e_j = \tau_j e_j$ and $\tau_j \in [0, +\infty)$ for each $j \geq 1$, such that

$$\sum_{j \geq 1} \tau_j \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j < \infty. \quad (54)$$

Lemma C.1. Under the assumptions above,

$$T^{1/2} A T^{1/2} := \sum_{j,k \geq 1} \tau_k^{1/2} \tau_j^{-1/2} \left( \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j \right) |e_k| \quad (55)$$

satisfies $0 \leq T^{1/2} A T^{1/2} = (T^{1/2} A T^{1/2})^* \in \mathcal{L}^1(\mathcal{H})$ and

$$\text{trace}_\mathcal{H}(T^{1/2} AT^{1/2}) = \sum_{j \geq 1} \tau_j \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j \quad (56)$$

In particular

$$e_j \in \text{Ker}(T) \implies e_j \in \text{Form-Dom}(A). \quad (57)$$

Proof. For each Borel $\omega \subset \mathbb{R}$ and each $x, y \in \mathcal{H}$, one has

$$|\langle x | E(\omega) | y \rangle| = |\langle E(\omega) x | E(\omega) y \rangle| \leq \|E(\omega) x\| \|E(\omega) y\| = \langle x | E(\omega) x \rangle \langle y | E(\omega) y \rangle.$$ \hspace{1cm}

since $E(\omega)$ is a self-adjoint projection. In particular, for each $\alpha > 0$, one has

$$2 |\langle x | E(\omega) | y \rangle| \leq \alpha \langle x | E(\omega) x \rangle + \frac{1}{\alpha} \langle y | E(\omega) y \rangle.$$ \hspace{1cm}

Hence, for all $j, k \geq 1$

$$a_{jk} := \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j \in \mathbb{C} \quad (58)$$

satisfies

$$2 |a_{jk}|^2 \leq \alpha a_{jj} + \frac{1}{\alpha} a_{kk} \quad (59)$$

for all $\alpha > 0$, so that $|a_{jk}| \leq a_{jj} a_{kk}$. Since $(\tau_j a_{jj})_{j \geq 1} \in \ell^1(\mathbb{N}^*)$ by (54) and since

$$\langle e_j | T^{1/2} A T^{1/2} e_k \rangle = \tau_k^{-1/2} \tau_j^{1/2} a_{jk} = \langle e_k | T^{1/2} A T^{1/2} e_j \rangle,$$

one concludes that $T^{1/2} A T^{1/2} = (T^{1/2} A T^{1/2})^* \in \mathcal{L}^2(\mathcal{H})$. Moreover, for each $x \in \mathcal{H}$

$$\langle x | T^{1/2} A T^{1/2} | x \rangle = \sum_{j,k \geq 1} \tau_k^{1/2} \tau_j^{-1/2} \langle e_j | x \rangle \langle e_k | x \rangle \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j \quad (58)$$

$$\geq \int_0^\infty \lambda \left( \sum_{j \geq 1} \tau_j^{1/2} \langle e_j | x \rangle \langle e_j | x \rangle \sum_{j \geq 1} \tau_j^{1/2} \langle e_j | e_j \rangle \right) \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j$$

$$= \int_0^\infty \lambda(T^{1/2} x | E(d\lambda) | T^{1/2} x) \geq 0,$$

so that $T^{1/2} A T^{1/2} \geq 0$. Finally

$$\sum_{l \geq 1} \langle e_l | T^{1/2} A T^{1/2} | e_l \rangle = \sum_{l \geq 1, j,k \geq 1} \tau_k^{1/2} \tau_j^{-1/2} \left( \int_0^\infty \lambda(\omega) |E(d\lambda)| e_j \right) \langle e_l | e_j \rangle \langle e_k | e_l \rangle$$

$$= \sum \sum \tau_k^{1/2} \tau_j^{1/2} \left( \int_0^\infty \lambda(\omega) |E(d\lambda)| e_k \right) \delta_{ij} \delta_{lk} = \sum \tau_l \int_0^\infty \lambda(\omega) |E(d\lambda)| e_l < \infty$$
so that $T^{1/2}AT^{1/2} \in \mathcal{L}^1(\mathcal{H})$, with

$$|T^{1/2}AT^{1/2}|_1 = \text{trace}_\mathcal{H}(T^{1/2}AT^{1/2}) = \sum_{l \geq 1} \tau_l \int_0^\infty \lambda(e_l|E(d\lambda)|e_l) < \infty.$$ 

In particular for each $j \geq 1$, one has

$$\tau_j > 0 \implies \langle e_j|A|e_j \rangle = \int_0^\infty \lambda(e_j|E(d\lambda)|e_j) \leq \frac{1}{\tau_j} \text{trace}_\mathcal{H}(T^{1/2}AT^{1/2}) < \infty,$$

and this proves (57). □

**Corollary C.2.** Let $\Phi_n \in C(\mathbb{R}_+)$ satisfy

$$0 \leq \Phi_1(r) \leq \Phi_2(r) \leq \ldots \leq \Phi_n(r) \to r \quad \text{as } n \to \infty.$$

For each $n \geq 1$, set

$$\Phi_n(A) := \int_0^\infty \Phi_n(\lambda)E(d\lambda) \in \mathcal{L}(\mathcal{H}), \quad \text{so that } \Phi_n(A) = \Phi_n(A)^* \geq 0.$$

In the limit as $n \to \infty$, one has

$$T^\dagger \Phi_n(A)T^\dagger \to T^\dagger AT^\dagger \quad \text{weakly, and } \text{trace}_\mathcal{H}(T \Phi_n(A)) \to \text{trace}_\mathcal{H}(T^\dagger AT^\dagger).$$

**Proof.** Since $E$ is a resolution of the identity on $[0, +\infty)$, and since $\Phi_n$ is continuous, bounded and with values in $[0, +\infty)$, the operators $\Phi_n(A)$ satisfy

$$0 \leq \Phi_1(A) \leq \Phi_2(A) \leq \ldots \leq \Phi_n(A) \leq \Phi_n(A)^* \leq \left(\sup_{z \geq 0} \Phi_n(z)\right) I_{\mathcal{H}}.$$

Set $R_n := T^{1/2}\Phi_n(A)T^{1/2}$; by definition, one has $R_n = R_n^* \in \mathcal{L}(\mathcal{H})$ and

$$0 \leq R_1 \leq R_2 \leq \ldots \leq R_n \leq \ldots$$

On account of (54), one has

$$\text{trace}_\mathcal{H}(R_n) = \sum_{j \geq 1} \int_0^\infty \Phi_n(\lambda)\langle e_j|E(d\lambda)|e_j \rangle \leq \sum_{j \geq 1} \tau_j \int_0^\infty \lambda(e_j|E(d\lambda)|e_j) < \infty.$$

By Lemma B.1, one has $R_n \to R$ weakly, with $R \in \mathcal{L}^1(\mathcal{H})$ and $R = R^* \geq 0$. Finally

$$T^{1/2}AT^{1/2} - R_n = \sum_{j,k \geq 1} \tau_j^{1/2} \tau_k^{1/2} \left(\int_0^\infty (\lambda - \Phi_n(\lambda))\langle e_j|E(d\lambda)|e_k \rangle\right)\langle e_j|e_k \rangle$$

using the definition (55) of $T^{1/2}AT^{1/2}$ given in Lemma C.1, so that

$$\langle x|T^{1/2}AT^{1/2} - R_n|x \rangle = \int_0^\infty (\lambda - \Phi_n(\lambda))\left(\sum_{j \geq 1} \tau_j^{1/2} \langle e_j|x \rangle E(d\lambda)\sum_{k \geq 1} \tau_k^{1/2} \langle e_k|x \rangle e_k\right)$$

$$= \int_0^\infty (\lambda - \Phi_n(\lambda))(T^{1/2}|x|E(d\lambda)|T^{1/2}x \rangle) \geq 0.$$

Hence $T^{1/2}AT^{1/2} - R_n = (T^{1/2}AT^{1/2} - R_n)^* \in \mathcal{L}^1(\mathcal{H})$ with $T^{1/2}AT^{1/2} - R_n \geq 0$, and

$$|T^{1/2}AT^{1/2} - R_n|_1 = \text{trace}_\mathcal{H}(T^{1/2}AT^{1/2} - R_n)$$

$$= \sum_{j \geq 1} \int_0^\infty (\lambda - \Phi_n(\lambda))\langle e_j|E(d\lambda)|e_j \rangle \to 0$$

as $n \to \infty$ by monotone convergence. Therefore $R_n \to T^{1/2}AT^{1/2}$ in $\mathcal{L}^1(\mathcal{H})$, and

$$\text{trace}_\mathcal{H}(T \Phi_n(A)) = \text{trace}_\mathcal{H}(T^{1/2}\Phi_n(A)T^{1/2}) \to \text{trace}_\mathcal{H}(T^{1/2}AT^{1/2}) \quad \text{as } n \to \infty.$$

□
**Lemma C.3.** Let $S \in \mathcal{L}^1(\mathcal{H} \otimes \overline{\mathcal{H}})$ satisfy the partial trace condition $\text{trace}_{\overline{\mathcal{H}}}(S) = T$. Then $0 \leq S^{1/2} (A \otimes I_{\overline{\mathcal{H}}}) S^{1/2} = (S^{1/2} (A \otimes I_{\overline{\mathcal{H}}}) S^{1/2})^* \in \mathcal{L}^1(\mathcal{H} \otimes \overline{\mathcal{H}})$ and one has

$$\text{trace}_{\mathcal{H} \otimes \overline{\mathcal{H}}}(S^{1/2} (A \otimes I_{\overline{\mathcal{H}}}) S^{1/2}) = \text{trace}_{\mathcal{H}}(T^{1/2} A T^{1/2}).$$

**Proof.** For all $n \geq 1$, set $A_n = \Phi_n(A) \in \mathcal{L}(S)$, with $\Phi_n(r) := \frac{r}{1 + \frac{1}{n}}$ for all $r \geq 0$. Thus

$$A_n = A_n^* \quad \text{and} \quad 0 \leq A_1 \leq A_2 \leq \ldots \leq A_n \leq \ldots$$

Hence $S^{1/2} (A_n \otimes I_{\overline{\mathcal{H}}}) S^{1/2} = (S^{1/2} (A_n \otimes I_{\overline{\mathcal{H}}}) S^{1/2})^*$ for all $n \geq 1$, with

$$0 \leq S^{1/2} (A_1 \otimes I_{\overline{\mathcal{H}}}) S^{1/2} \leq S^{1/2} (A_2 \otimes I_{\overline{\mathcal{H}}}) S^{1/2} \leq \ldots \leq S^{1/2} (A_n \otimes I_{\overline{\mathcal{H}}}) S^{1/2} \leq \ldots$$

The partial trace condition implies that

$$\text{trace}_{\mathcal{H} \otimes \overline{\mathcal{H}}}(S^{1/2} (A_n \otimes I_{\overline{\mathcal{H}}}) S^{1/2}) = \text{trace}_{\mathcal{H} \otimes \overline{\mathcal{H}}}(S(A_n \otimes I_{\overline{\mathcal{H}}}))$$

$$= \text{trace}_{\mathcal{H}}(T A_n) = \text{trace}_{\mathcal{H}}(T^{1/2} A_n T^{1/2})$$

while

$$\text{trace}_{\mathcal{H} \otimes \overline{\mathcal{H}}}(S^{1/2} (A_n \otimes I_{\overline{\mathcal{H}}}) S^{1/2}) \rightarrow \text{trace}_{\mathcal{H} \otimes \overline{\mathcal{H}}}(S^{1/2} (A \otimes I_{\overline{\mathcal{H}}}) S^{1/2})$$

$$\text{trace}_{\mathcal{H}}(T^{1/2} A_n T^{1/2}) \rightarrow \text{trace}_{\mathcal{H}}(T^{1/2} A T^{1/2})$$

as $n \rightarrow \infty$ by Lemma B.1. This implies the announced equality by uniqueness of the limit. \hfill $\Box$
