Points on Curves in Small Boxes and Applications

MEI-CHU CHANG, JAVIER CILLERUELO, MOUBARIZ Z. GARAEV, JOSÉ HERNÁNDEZ, IGOR E. SHPARLINSKI, & ANA ZUMALACÁRREGUI

Abstract. We introduce several new methods to obtain upper bounds on the number of solutions of the congruences

\[ f(x) \equiv y \pmod{p} \quad \text{and} \quad f(x) \equiv y^2 \pmod{p}, \]

with a prime \( p \) and a polynomial \( f \), where \((x, y)\) belongs to an arbitrary square with side length \( M \). We give two applications of these results to counting hyperelliptic curves in isomorphism classes modulo \( p \) and to the diameter of partial trajectories of a polynomial dynamical system modulo \( p \).

1. Introduction

1.1. Motivation

Studying the distribution of integer and rational points on curves and, more generally, on algebraic varieties that belong to a given box is a classical topic in analytic number theory. For the case of plane curves with integer coefficients, essentially the best possible results are due to Bombieri and Pila [6; 32; 33]. Furthermore, recently remarkable progress has been made in the case of hypersurfaces and varieties over the rationals; see the surveys [8; 21; 36] and the original works [27; 28; 34].

Significantly less is known about the distribution of points in boxes on curves and varieties in finite fields. For reasonably large boxes, bounds on exponential sums, which are based on deep methods of algebraic geometry, lead to asymptotic formulas for the number of such points; see [17; 18; 26]. Certainly, when the size of the box is decreasing, beyond a certain threshold no asymptotic formula is possible (in fact, the expected number of points can be less than 1). In particular, for such a small box, we can only expect to derive upper bounds on the number of points on curves that hit it. This question has recently been introduced in [13], where a series of general results has been obtained (we also mention the works [9; 12; 42], where this question has been studied for some very special curves).

In this paper, we introduce new ideas and make significant advances in this direction. We find connections between the problem of distribution of points in small boxes on modular curves with some delicate combinations of results from geometry of numbers, Diophantine approximation theory, the Vinogradov mean value theorem, and the Weyl method.
Note that in the case of curves modulo $p$, it is not quite clear what can be expected as an “optimal” result (in contrast to the case of estimating integer points in boxes on plane curves over $\mathbb{Q}$). Yet in some parameter ranges, our results are the best possible and can be considered as modulo $p$ analogues of the results of Bombieri and Pila [6; 32; 33].

Although our results are related to classical problems, here we also give two further applications:

First of all, we study the distribution of isomorphism classes of hyperelliptic curves of genus $g \geq 1$ in some families of curves associated with polynomials with coefficients in a small box. In the case of elliptic curves, this question has been studied in [14]. Here we improve some results of [14] and also use new methods to study the case of $g \geq 2$. Surprisingly enough, in the case of the genus $g \geq 2$, we obtain estimates and use methods that do not apply to elliptic curves (that is, to $g = 1$).

Second, we consider polynomial dynamical systems and study for how long a particular trajectory of such a system can be “locked” in a given box. In particular, we extend and improve several results of [10; 11; 13; 19].

### 1.2. Basic Definitions and Problem Formulation

For a prime $p$, let $\mathbb{F}_p$ denote the finite field of $p$ elements, which we assume to be represented by the set $\{0, 1, \ldots, p - 1\}$.

Let $f \in \mathbb{F}_p[X]$ be a polynomial of degree $m \geq 2$. Then for $1 \leq M < p$, we define $J_f(M; R, S)$ as the number of solutions to the congruence

$$y \equiv f(x) \pmod{p}, \quad (x, y) \in [R + 1, R + M] \times [S + 1, S + M].$$

This quantity has been the primal object of study in [13]. Here we consider a substantially more complicated case.

Given a polynomial $f \in \mathbb{F}_p[X]$ of degree $m \geq 3$ and a positive integer $M < p$, we denote by $I_f(M; R, S)$ the number of solutions to the congruence

$$y^2 \equiv f(x) \pmod{p}$$

with

$$(x, y) \in [R + 1, R + M] \times [S + 1, S + M].$$

If the polynomial $y^2 - f(x)$ is absolutely irreducible, it is known from the Weil bounds that

$$I_f(M; R, S) = \frac{M^2}{p} + O(p^{1/2} \log p)^2,$$

where the implied constant depends only on $m$; see [37; 41]. It is clear that the main term is dominated by the error term for $M \leq p^{3/4} \log p$, and for $M \leq p^{1/2} \log p$, the result becomes weaker than the trivial upper bound $I_f(M; R, S) \leq 2M$. Here we use a different approach and give a nontrivial estimate of $I_f(M; R, S)$ for $M < p^{1/3 - \varepsilon}$ when $m \geq 3$. In particular, in the case $m = 3$, our result improves on the range of $M$ the bound obtained in [14].
Furthermore, we also obtain a new bound on $J_f(M; R, S)$, which improves that of [13].

We also mention that nontrivial bounds on the number of solutions $(x, y)$ to the congruences

$$xy \equiv a \pmod{p}$$

and

$$y \equiv \vartheta^x \pmod{p}$$

satisfying (2) have been given in [9] with further improvements in [12]. Similar results for the congruence

$$Q(x, y) \equiv 0 \pmod{p},$$

where $Q(x, y)$ is an absolutely irreducible quadratic form with a nonzero discriminant, can be found in [42].

1.3. General Notation

Throughout the paper, any implied constants in the symbols $O$, $\ll$ and $\gg$ may occasionally depend, where obvious, on the degree of polynomial $f \in \mathbb{F}_p[X]$, on the genus $g$, and on the real positive parameters $\varepsilon$ and $\delta$, and are absolute otherwise. We recall that the notations $U = O(V)$, $U \ll V$, and $V \gg U$ are all equivalent to the statement that $|U| \leq cV$ with some constant $c > 0$.

The letters $h, m, n, r, s$ in both upper and lower cases always denote integer numbers.

2. Main Results

2.1. Points on Curves in Small Boxes

We combine ideas from [12; 13; 14] with some new ideas and derive the following results.

**Theorem 1.** Uniformly over all polynomials $f \in \mathbb{F}_p[X]$ of degree $\deg f = 3$ and $1 \leq M < p$, we have

$$I_f(M; R, S) < M^{1/3+o(1)} + \frac{M^{5/3+o(1)}}{p^{1/6}}$$

as $M \to \infty$.

One of the implications of Theorem 1 is that for elliptic curves, that is, when the polynomial $f$ in (1) is cubic, the bound $I_f(M; R, S) < M^{1/3+o(1)}$ holds for $M \ll p^{1/8}$, while [14, Theorem 5.1] guarantees this bound only for $M \ll p^{1/9}$. The range in which we have $I_f(M; R, S) < M^{1/3+o(1)}$ is of interest because this bound is essentially the best possible. In fact it is easy to see that for any positive $M < p$ and, say $f(X) = X^m$, examining the points $(x, y) = (t^m, t^2)$, $1 \leq t \leq M^{1/m}$, we conclude that

$$I_f(M; 0, 0) \gg M^{1/m}.$$
We also note that when \( \deg f = 3 \), our upper bounds for \( I_f(M; R, S) \) imply the same bounds for \( N(H; \mathfrak{F}) \) in the case of elliptic curves.

Further, when \( M < p^{1/4-\varepsilon} \) for some \( \varepsilon > 0 \), Theorem 1 guarantees a nontrivial bound \( I_f(M; R, S) \ll M^{1-\delta} \) with some \( \delta > 0 \) that depends only on \( \varepsilon \), improving upon the range \( M < p^{1/5-\varepsilon} \) obtained in [14]. However, using a new approach, we obtain the following bound, which is nontrivial in the range \( M < p^{1/3-\varepsilon} \).

**Theorem 2.** Uniformly over all polynomials \( f \in \mathbb{F}_p[X] \) of degree \( \deg f = 3 \) and \( M \geq 1 \), we have

\[
I_f(M; R, S) \leq M^{1/3+o(1)} + \left( \frac{M^3}{p} \right)^{1/16} M^{1+o(1)}.
\]

The proof of Theorem 2 is based on combinations of results from the geometry of numbers, the current state of art on Vinogradov’s mean value theorem due to Wooley [39; 40] and the Diophantine approximation theory. Our use of the geometry of numbers is close to the ideas of Bourgain et al. [7].

The combination of Theorems 1 and 2 gives the following estimate.

**Corollary 3.** Uniformly over all polynomials \( f \in \mathbb{F}_p[X] \) of degree \( \deg f = 3 \) and \( 1 \leq M < p \), we have

\[
I_f(M; R, S) < M^{1+o(1)} \begin{cases} 
M^{-2/3} & \text{if } M < p^{1/8}, \\
(M^4/p)^{1/6} & \text{if } p^{1/8} \leq M < p^{5/23}, \\
(M^3/p)^{1/16} & \text{if } p^{5/23} \leq M < p^{1/3}, 
\end{cases}
\]

as \( M \to \infty \).

Our next result shows that when \( \deg f \geq 4 \), we also have a nontrivial bound for \( I_f(M; R, S) \) in the range \( M < p^{1/3-\varepsilon} \).

To formulate our result, we define \( J_{k,m}(H) \) as the number of solutions of the system of \( m \) Diophantine equations in \( 2k \) integral variables \( x_1, \ldots, x_{2k} \):

\[
\begin{align*}
x_1^m + \cdots + x_k^m &= x_{k+1}^m + \cdots + x_{2k}^m, \\
&\vdots \\
x_1 + \cdots + x_k &= x_{k+1} + \cdots + x_{2k},
\end{align*}
\]

\( 1 \leq x_1, \ldots, x_{2k} \leq H. \) \hspace{1cm} (4)

We also define \( \kappa(m) \) to be the smallest integer \( \kappa \) such that for any integer \( k \geq \kappa \), there exists a constant \( C(k, m) \) depending only on \( k \) and \( m \) and such that

\[
J_{k,m}(H) \leq C(k, m) H^{2k-m(m+1)/2+o(1)}
\]

as \( H \to \infty \). Note that by a recent result of Wooley [40, Theorem 1.1], which improves the previous estimate of [39], we have \( \kappa(m) \leq m^2 - 1 \) for any \( m \geq 3 \).
**Theorem 4.** Uniformly over all polynomials $f \in \mathbb{F}_p[X]$ of degree $\deg f = m \geq 4$ and $1 \leq M < p$, we have

$$I_f(M; R, S) \leq M(M^3/p)^{1/2\kappa(m)+o(1)} + M^{1-(m-3)/2\kappa(m)+o(1)}$$

as $M \to \infty$.

In particular, for any $\varepsilon > 0$, there exists $\delta > 0$ that depends only on $\varepsilon$ and $\deg f$ such that if $M < p^{1/3-\varepsilon}$ and $\deg f \geq 4$, then $I_f(M; R, S) \ll M^{1-\delta}$.

2.2. Polynomial Values in Small Boxes

We also prove a new estimate on $J_f(M; R, S)$.

**Theorem 5.** Let $f \in \mathbb{F}_p[X]$ be a polynomial of degree $m \geq 2$. Then for $1 \leq M < p$, we have

$$J_f(M; R, S) \ll \frac{M^2}{p} + M^{1-1/2m-1}p^{o(1)}$$

as $p \to \infty$.

We remark that for large values of $m$, some bounds of [13], obtained by a different method, are better than Theorem 5. However, for small values of $m$ (for example, for $m = 2, 3$), Theorem 5 gives stronger estimates.

3. Applications

3.1. Isomorphism Classes of Hyperelliptic Curves in Thin Families

A special case of equation (1) is hyperelliptic curves over $\mathbb{F}_p$. The problem of concentration of points on hyperelliptic curves and polynomial maps is connected with some problems on isomorphisms that preserve hyperelliptic curves. Let $g$ be a fixed positive integer constant. We always assume that $p$ is large enough so that, in particular, we have $\gcd(p, 2(2g+1)) = 1$. Any hyperelliptic curve can be given by a nonsingular Weierstrass equation

$$H_a: \quad Y^2 = X^{2g+1} + a_{2g-1}X^{2g-1} + \cdots + a_1X + a_0,$$

where $a = (a_0, \ldots, a_{2g-1}) \in \mathbb{F}_p^{2g}$ (we recall that the nonsingularity condition is equivalent to nonvanishing of the discriminant of the polynomial $X^{2g+1} + a_{2g-1}X^{2g-1} + \cdots + a_1X + a_0$). We refer to [1] for a background on hyperelliptic curves and their applications.

It follows from a more general result of Lockhart [25, Proposition 1.2] that isomorphisms that preserve hyperelliptic curves given by Weierstrass equations are all of the form $(x, y) \mapsto (\alpha^2x, \alpha^{2g+1}y)$ for some $\alpha \in \mathbb{F}_p^*$; see also [23, Section 3]. Thus, $H_a$ is isomorphic to $H_b$, which we denote as $H_a \sim H_b$, if there exists $\alpha \in \mathbb{F}_p^*$ such that

$$a_i \equiv \alpha^{4g+2-2i}b_i \pmod{p}, \quad i = 0, \ldots, 2g-1. \quad (6)$$
It is known (see [23; 30]) that the number of nonisomorphic hyperelliptic curves of genus \( g \) over \( \mathbb{F}_p \) is \( 2p^{2g-1} + O(gp^{2g-2}) \). We address here the problem of estimating from below the number \( H_a \) of nonisomorphic hyperelliptic curves of genus \( g \) over \( \mathbb{F}_p \) when \( a = (a_0, \ldots, a_{2g-1}) \) belongs to a small \( 2g \)-dimensional cube

\[
\mathcal{B} = [R_0 + 1, R_0 + M] \times \cdots \times [R_{2g-1} + 1, R_{2g-1} + M]
\]

with some integers \( R_j \) and \( M \) satisfying \( 0 \leq R_j < R_j + M < p \), \( j = 0, \ldots, 2g - 1 \).

In particular, we note that all components of a vector \( a \in \mathcal{B} \) are nonzero modulo \( p \). Our methods work without this restriction as well; however, they somewhat lose their efficiency.

We also give an upper bound for the number

\[
N(H; \mathcal{B}) = \#\{a = (a_0, \ldots, a_{2g-1}) \in \mathcal{B} : H_a \sim H\}
\]

of hyperelliptic curves \( H_a \) with \( a \in \mathcal{B} \) that are isomorphic to a given curve \( H \).

In particular, our estimates extend and improve some results of [14], where this problem has been investigated for elliptic curves (that is, for \( g = 1 \)).

First, we observe that for large cubes, we easily derive from the Weil bound (see [22, Chapter 11]) the asymptotic formula

\[
N(H; \mathcal{B}) = \frac{M^{2g}}{p^{2g-1}} + O(p^{1/2}(\log p)^{2g})
\]

(see also the proof of [22, Theorem 21.4]). So we have an asymptotic formula for \( N(H; \mathcal{B}) \) as long as \( M \geq p^{1-1/(4g)+\varepsilon} \) for any fixed \( \varepsilon > 0 \).

However, here we are mostly interested in small values of \( M \).

We note that we always have the trivial upper bound

\[
N(H; \mathcal{B}) \leq 2M.
\]

To see this, let \( H = H_b \), \( b = (b_0, \ldots, b_{2g-1}) \in \mathbb{F}_p^{2g} \), be given by a Weierstrass equation. We observe that if \( H_a \sim H \) and \( H = H_b \), where \( b = (b_0, \ldots, b_{2g-1}) \in \mathbb{F}_p^{2g} \), then \( a_{2g-1} \) can take at most \( M \) values in \( \mathbb{F}_p^* \), and each \( a_{2g-1} \) determines two possible values for \( a_2 \) in (6).

It is also useful to remark that one cannot expect to get a general bound stronger than

\[
N(H; \mathcal{B}) = O(M^{1/(2g+1)}).
\]

To see this, we consider the set \( Q \) of quadratic residues modulo \( p \) in the interval \([1, M^{1/(2g+1)}]\). It is well known that for almost all primes \( p \) (that is, for all except a set of relative density zero), we have

\[
\#Q \sim 0.5M^{1/(2g+1)} \quad \text{as} \quad M \to \infty.
\]

For example, this follows from a bound of Heath-Brown [20, Theorem 1] on average values of sums of real characters.

Consider now the set

\[
\mathcal{A} = \{\alpha \in \mathbb{F}_p : \alpha^2 \in Q\},
\]
the curve $H: Y^2 = X^{2g+1} + X^{2g-1} + X^{2g-2} + \ldots + X + 1$, and the $2g$-dimensional cube $\mathcal{B} = [1, M]^{2g}$. It is clear that $(\alpha^4, \alpha^6, \ldots, \alpha^{4g+2}) \in \mathcal{B}$ for all $\alpha \in \mathcal{A}$. On the other hand, $\# \mathcal{A} = 2\# \mathcal{Q} \sim M^{1/(2g+1)}$.

We now turn to estimates on $N(H; \mathcal{B})$ given by (8). A simple observation shows that in the case of hyperelliptic curves with $g \geq 2$, the quantity $N(H; \mathcal{B})$ is closely related to the problem of concentration of points of a quadratic polynomial map. Then we can apply the general result of [13] and get a nontrivial upper bound for $N(H; \mathcal{B})$ for any range of $M$. However, here we use a different approach and obtain a better bound.

Using (6), from Theorem 5 and the bound of [13]

$$J_f (M; R, S) \ll M^{1/m+o(1)},$$

which holds for $M \leq p^{2/(m^2+3)}$, we derive the following consequence.

**Theorem 6.** For any hyperelliptic curve $H$ of genus $g \geq 2$ over $\mathbb{F}_p$ and any cube $\mathcal{B}$ given by (7) with $1 \leq M < p$, we have

$$N(H; \mathcal{B}) \ll \frac{M^2}{p} + M^{1/2+o(1)}.$$

Furthermore, as we have mentioned before, when $g = 1$, the problem of estimating $N(H; \mathcal{B})$ is equivalent to estimating the concentration of points on certain curves of degree 3 (which are singular and thus are not elliptic curves), and Theorem 1 applies in this case. Using the idea of the proof of Theorem 1, we establish the following result, which is valid for any hyperelliptic curve.

**Theorem 7.** For any hyperelliptic curve $H$ of genus $g \geq 1$ over $\mathbb{F}_p$, any cube $\mathcal{B}$ given by (7) with $1 \leq M < p$, and any odd integer $h \in [3, 2g+1]$, we have

$$N(H; \mathcal{B}) < (M^{1/h} + M(M^4/p)^{2/h(h+1)})M^{o(1)}$$

as $M \to \infty$.

We observe that if $M < p^{1/(2g^2+2g+4)}$, then, taking $h = 2g + 1$ in Theorem 7, we obtain the estimate $N(H; \mathcal{B}) \leq M^{1/(2g+1)+o(1)}$, which, as we have seen, is sharp up to the $o(1)$ term.

Let $\mathcal{H}(\mathcal{B})$ be the collection of representatives of all isomorphism classes of hyperelliptic curves $H_a$, $a \in \mathcal{B}$, where $\mathcal{B}$ is a $2g$-dimensional cube of side length $M$. In [14], the lower bound $\# \mathcal{H}(\mathcal{B}) \gg \min\{p, M^{2+o(1)}\}$ has been obtained for elliptic curves (that is, for $g = 1$). We extend this result to $g \geq 2$. Certainly, the upper bounds of our theorems lead to a lower bound on $\# \mathcal{H}(\mathcal{B})$. However, using a different approach, we obtain a near optimal bound for $\# \mathcal{H}(\mathcal{B})$.

**Theorem 8.** For $g \geq 1$ and any cube $\mathcal{B}$ given by (7) with $1 \leq M < p$, we have

$$\# \mathcal{H}(\mathcal{B}) \gg \min\{p^{2g-1}, M^{2g+o(1)}\}$$

as $M \to \infty$. Furthermore, if $g \geq 2$, then the $o(1)$ term can be removed when $M > p^{1/(2g)}$. 

3.2. Diameter of Polynomial Dynamical Systems

Results about concentration of points on curves are also closely related to the question about the diameter of partial trajectories of polynomial dynamical systems. Namely, given a polynomial $f \in \mathbb{F}_p[X]$ and an element $u_0 \in \mathbb{F}_p$, we consider the sequence of elements of $\mathbb{F}_p$ generated by iterations $u_n = f(u_{n-1})$, $n = 0, 1, \ldots$. Clearly, the sequence $u_n$ is eventually periodic. In particular, let $T_{f,u_0}$ be the full trajectory length, that is, the smallest integer $t$ such that $u_t = u_s$ for some $s < t$. The study of the diameter

$$D_{f,u_0}(N) = \max_{0 \leq k,m \leq N-1} |u_k - u_m|$$

has been initiated in [19] and then continued in [10; 11; 13]. In particular, it follows from [19, Theorem 6] that for any fixed $\varepsilon$ and for $T_{f,u_0} \geq N \geq p^{1/2+\varepsilon}$, we have the asymptotically best possible bound

$$D_{f,u_0}(N) = p^{1+o(1)}$$

as $p \to \infty$. For smaller values of $N$, a series of lower bounds on $D_{f,u_0}(N)$ is given in [10; 11; 13].

The following estimate can be easily derived from Theorem 5; it improves several previous results to intermediate values of $N$ (and is especially effective for small values of $m$).

**Corollary 9.** For any polynomial $f \in \mathbb{F}_p[X]$ of degree $m \geq 2$ and positive integer $N \leq T_{f,u_0}$, we have

$$D_{f,u_0}(N) \gg \min\{N^{1/2}p^{1/2}, N^{1+1/(2m-1)}p^{o(1)}\}$$

as $p \to \infty$.

On the other hand, we remark that our method and results do not affect the super-polynomial lower bounds of [10; 11] that hold for small values of $N$.

4. Preparations

4.1. Uniform Distribution and Exponential Sums

The following result is well known and can be found, for example, in [29, Chapter 1, Theorem 1] (which is a more precise form of the celebrated Erdős–Turán inequality).

**Lemma 10.** Let $\gamma_1, \ldots, \gamma_M$ be a sequence of $M$ points of the unit interval $[0, 1]$. Then for any integer $K \geq 1$ and an interval $[\alpha, \beta] \subseteq [0, 1]$, we have

$$\#\{n = 1, \ldots, M: \gamma_n \in [\alpha, \beta]\} - M(\beta - \alpha) \ll \frac{M}{K} + \sum_{k=1}^{K}\left(\frac{1}{K} + \min\{\beta - \alpha, 1/k\}\right)\left|\sum_{n=1}^{M}\exp(2\pi i k \gamma_n)\right|.$$
To use Lemma 10, we also need an estimate on exponential sums with polynomials, which is essentially due to Weyl; see [22, Proposition 8.2].

Let \( \| \xi \| = \min \{ |\xi - k| : k \in \mathbb{Z} \} \) denote the distance between a real \( \xi \) and the closest integer.

**Lemma 11.** Let \( f(X) \in \mathbb{R}[X] \) be a polynomial of degree \( m \geq 2 \) with the leading coefficient \( \vartheta \neq 0 \). Then

\[
\left| \sum_{n=1}^{M} \exp(2\pi i f(n)) \right| \ll M^{-m/2^{m-1}} \left( \sum_{-M < \ell_1, \ldots, \ell_{m-1} < M} \min \{ M, \| \vartheta m! \ell_1 \ldots \ell_{m-1} \|^{-1} \} \right)^{2^{-m}}.
\]

### 4.2. Integer Points on Curves and Varieties

We also need the following estimate of Bombieri and Pila [6] on the number of integral points on plane polynomial curves.

**Lemma 12.** Assume that \( C \) is a plane absolutely irreducible curve of degree \( d \geq 2 \) and \( H \geq \exp(d^{6}) \). Then the number of integral points on \( C \) and inside a square \([0, H] \times [0, H] \) does not exceed

\[
H^{1/d} \exp(12\sqrt{d \log H \log \log H}.
\]

The following statement is a particular case of a more general result of Wooley [40, Theorem 1.1].

**Lemma 13.** The number of solutions of the system of Diophantine equations

\[
x_1^j + \cdots + x_8^j = x_9^j + \cdots + x_{16}^j, \quad j = 1, 2, 3,
\]

in integers \( x_i \) with \( |x_i| \leq M, i = 1, \ldots, 16 \), is at most \( M^{10+o(1)} \).

**Proof.** Writing \( x_i = X_i - M - 1 \) with a positive integer \( X_i \leq 2M + 1, i = 1, \ldots, 16 \), after some trivial algebraic transformation, we see that the number of solutions to the above equation is equal to \( J_{8,3}(2M + 1) \). Since by the result of Wooley [40, Theorem 1.1] we have \( \kappa(3) \leq 8 \), the bound (5) applies with \( H = 2M + 1 \).

We note that Lemma 13 can be formulated in a more general form with \( \kappa(3) \) instead of eight variables on each side, but this generalization (assuming possible improvements of the bound \( \kappa(3) \leq 8 \)) does not affect our main results.

### 4.3. Congruences with Many Solutions

The following result is used in the proofs of Theorems 1 and 7.

**Lemma 14.** Let \( f, g \in \mathbb{F}_p[X] \) be two polynomials of degrees \( n \) and \( m \) such that \( m \nmid n \). Assume that the integers \( x_1, \ldots, x_n \) are pairwise distinct modulo \( p \) and...
\(y_1, \ldots, y_n\) are arbitrary integers. Then the congruence

\[ f(x) \equiv g(y) \pmod{p}, \quad 0 \leq x, y < p, \] (10)

has at most \(mn\) solutions with

\[
\det \begin{pmatrix} x^n & x^{n-1} & \cdots & x & y \\ x_1^n & x_1^{n-1} & \cdots & x_1 & y_1 \\ \vdots \\ x_n^n & x_n^{n-1} & \cdots & x_n & y_n \end{pmatrix} \equiv 0 \pmod{p}. \tag{11}
\]

Proof. Since

\[
\det \begin{pmatrix} x_1^n & x_1^{n-1} & \cdots & x_1 \\ \vdots \\ x_n^n & x_n^{n-1} & \cdots & x_n \end{pmatrix} = x_1 \cdots x_n \prod_{1 \leq i < j \leq n} (x_i - x_j) \not\equiv 0 \pmod{p},
\]

we deduce that, for any \(x\) and \(y\), the last column in (11) is a unique modulo \(p\) linear combination of the previous columns. In particular, for every solution \((x, y)\) to (10) and (11), we have \(y \equiv h(x) \pmod{p}\) for some nontrivial polynomial \(h(X) \in \mathbb{F}_p[X]\) that does not depend on \(x\) and \(y\).

Now we insert this into (10). We observe that now the right-hand side of (10), that is, \(g(h(x))\), is a nontrivial polynomial of degree \(m\ deg h\). Thus, the congruence (10) is a nontrivial polynomial congruence of degree \(d\) with \(n \leq d \leq mn\). Therefore, it has at most \(mn\) solutions modulo \(p\). \[\square\]

4.4. Symmetric Multiplicative Congruences

For given positive integers \(i, j\), we define \(T_{i,j}(R, S; M)\) as the number of solutions to the congruence

\[ r^i v^j \equiv u^i s^j \pmod{p} \]

with \((r, s), (u, v) \in [R + 1, R + M] \times [S + 1, S + M]\).

It has been shown in [14, Theorem 4.1] that for a positive \(M < p\), we have

\[ T_{i,j}(R, S; M) = d \frac{M^4}{p - 1} + O(M^2 p^{o(1)}) \] (12)

as \(M \to \infty\), where \(d = \gcd(i, j, p - 1)\). We need a slight modification of that statement, where \(p^{o(1)}\) is replaced by \(M^{o(1)}\).

Lemma 15. For any prime \(p\) and any integers \(M, R, S\) with

\[
R, S \geq 0, \quad M \geq 1 \quad \text{and} \quad R + M, S + M < p,
\]

we have,

\[ T_{i,j}(R, S; M) = d \frac{M^4}{p - 1} + O(M^{2+o(1)}) \]

as \(M \to \infty\), where \(d = \gcd(i, j, p - 1)\), and the implied constant depends only on \(i\) and \(j\).
Proof. We note that for $M \geq p^{1/2}$, the result follows from (12). For $M < p^{1/2}$, the result is equivalent to the upper bound $T_{i,j}(R, S; M) \leq M^{2+o(1)}$ since the implied constant is allowed to depend on $d$.

As in the proof of [14, Theorem 4.1], using the orthogonality of multiplicative characters, we write

$$T_{i,j}(R, S; M) = \sum_{r,u=R+1}^{R+M} \sum_{s,v=S+1}^{S+M} \frac{1}{p-1} \sum_{\chi \in \mathcal{X}} \chi((r/u)^i(v/s)^j) \chi(r) \chi(s)^2.$$

We estimate the contribution to the above sum from at most $i + j$ characters $\chi$ with $\chi^i = \chi_0$ or $\chi^j = \chi_0$, where $\chi_0$ is the principal character, as $O(M^4/p) = O(M^{2+o(1)})$.

The rest of the sum can also be estimated as $O(M^{2+o(1)})$ by following exactly the same argument as in [14, Theorem 4.1] and using [14, Lemma 2.2].

4.5. Background on Geometry of Numbers

We recall that a lattice in $\mathbb{R}^n$ is an additive subgroup of $\mathbb{R}^n$ generated by $n$ linearly independent vectors. Let $D$ be a symmetric convex body, that is, $D$ is a compact convex subset of $\mathbb{R}^n$ with nonempty interior that is centrally symmetric with respect to 0. Then, for a lattice in $\Gamma \subseteq \mathbb{R}^n$ and $i = 1, \ldots, n$, the $i$th successive minimum $\lambda_i(D, \Gamma)$ of the set $D$ with respect to the lattice $\Gamma$ is defined as the minimal number $\lambda$ such that the set $\lambda D$ contains $i$ linearly independent vectors of the lattice $\Gamma$. In particular, $\lambda_1(D, \Gamma) \leq \cdots \leq \lambda_n(D, \Gamma)$. We recall the following result given in [3, Proposition 2.1] (see also [35, Exercise 3.5.6] for a simplified form, which is still enough for our purposes).

**Lemma 16.** We have

$$\#(D \cap \Gamma) \leq \prod_{i=1}^{n} \left( \frac{2i}{\lambda_i(D, \Gamma)} + 1 \right).$$

Using that

$$\frac{2i}{\lambda_i(D, \Gamma)} + 1 \leq (2i + 1) \max \left\{ \frac{1}{\lambda_i(D, \Gamma)}, 1 \right\}$$

and denoting, as usual, by $(2n + 1)!!$ the product of all odd positive numbers up to $2n + 1$, we derive the following:

**Corollary 17.** We have

$$\prod_{i=1}^{n} \min\{\lambda_i(D, \Gamma), 1\} \leq (2n + 1)!! \#(D \cap \Gamma)^{-1}.$$
5. Proofs

5.1. Proof of Theorem 1

For brevity, in this section we denote \( I = I_f(M; R, S) \). We can assume that \( I \) is large. We fix some integer \( L \) such that

\[
1 \leq L \leq 0.01 I,
\]

(13)
to be chosen later. By the pigeonhole principle, there exists \( Q \) such that the congruence

\[
y^2 \equiv f(x) \pmod{p}, \quad Q + 1 \leq x \leq Q + M/L, \quad S + 1 \leq y \leq S + M,
\]

has at least \( I/L \) solutions. We can split the interval \([Q + 1, Q + M/L]\) into \( k_0 = \lceil I/(30L) \rceil \) intervals of length not greater than \( 30M/I \). Since there are at most two solutions to the above congruence with the same value of \( x \), and since we have at least \( I/L > 20k_0 \) solutions in total, from the pigeonhole principle it follows that there exists an interval of length \( 30M/I \) containing at least 10 pairwise distinct values of \( x \). Let \( x_0 \) be the first of these values, and let \((x_0, y_0)\) be the corresponding solution. It is clear that \( I/L \) is bounded by the number of solutions of

\[
(y_0 + y)^2 \equiv f(x_0 + x) \pmod{p}, \quad -M/L \leq x \leq M/L, \quad -M \leq y \leq M,
\]

which is equivalent to

\[
y^2 \equiv c_3x^3 + c_2x^2 + c_1x + c_0y \pmod{p}, \quad -M/L \leq x \leq M/L, \quad -M \leq y \leq M,
\]

(14)
with \((c_3, p) = 1\). Besides, there are at least 10 solutions \((x, y)\) with pairwise distinct \( x \) and such that \( 0 \leq x \leq 30M/I \). From these 10 values we fix three solutions \((x_1, y_1), (x_2, y_2), (x_3, y_3)\) and rewrite the congruence (14) in the matrix form

\[
\begin{pmatrix}
x^3 & x^2 & x & y \\
x_3^3 & x_3^2 & x_3 & y_3 \\
x_2^3 & x_2^2 & x_2 & y_2 \\
x_1^3 & x_1^2 & x_1 & y_1
\end{pmatrix}
\begin{pmatrix}
c_3 \\
c_2 \\
c_1 \\
c_0
\end{pmatrix}
\equiv
\begin{pmatrix}
y^2 \\
y_3^2 \\
y_2^2 \\
y_1^2
\end{pmatrix} \pmod{p}.
\]

(15)

By Lemma 14 we know that at most six pairs \((x, y)\), with pairwise distinct \( x \), satisfy both the congruence (15) and the congruence

\[
\begin{vmatrix}
x^3 & x^2 & x & y \\
x_3^3 & x_3^2 & x_3 & y_3 \\
x_2^3 & x_2^2 & x_2 & y_2 \\
x_1^3 & x_1^2 & x_1 & y_1
\end{vmatrix}
\equiv 0 \pmod{p}.
\]
Since there are at least 10 solutions to (15), for one of them, say \((x_4, y_4)\), we have

\[
\Delta = \begin{vmatrix}
x_4^3 & x_4^2 & x_4 & y_4 \\
x_3^3 & x_3^2 & x_3 & y_3 \\
x_2^3 & x_2^2 & x_2 & y_2 \\
x_1^3 & x_1^2 & x_1 & y_1 \\
\end{vmatrix} \neq 0 \pmod{p}.
\]

Note that \(1 \leq |\Delta| \ll (M/I)^6 M\). Now we solve the system of congruences

\[
\begin{pmatrix}
x_4^3 & x_4^2 & x_4 & y_4 \\
x_3^3 & x_3^2 & x_3 & y_3 \\
x_2^3 & x_2^2 & x_2 & y_2 \\
x_1^3 & x_1^2 & x_1 & y_1 \\
\end{pmatrix} \begin{pmatrix} c_3 \\ c_2 \\ c_1 \\ c_0 \end{pmatrix} \equiv \begin{pmatrix} y_4^2 \\ y_3^2 \\ y_2^2 \\ y_1^2 \end{pmatrix} \pmod{p}
\]

with respect to \((c_3, c_2, c_1, c_0)\). We write \(\Delta_j\) for the determinant of the matrix on the left-hand side, where we have substituted the column \(j\) by the vector \((y_4^2, y_3^2, y_2^2, y_1^2)\). With this notation we have that

\[ c_j \equiv \Delta_{4-j} \Delta^* \pmod{p}, \quad j = 0, \ldots, 3, \]

where \(\Delta^*\) is defined by \(\Delta \Delta^* \equiv 1 \pmod{p}\), and the congruence (14) is equivalent to

\[
\Delta_1 x^3 + \Delta_2 x^2 + \Delta_3 x + \Delta_4 y - \Delta y^2 \equiv 0 \pmod{p}.
\]

In particular, since, as we have noticed, \(c_3 \equiv 0 \pmod{p}\), we have that \(\Delta_1 \equiv 0 \pmod{p}\). We can write this congruence as an equation over \(\mathbb{Z}\):

\[
\Delta_1 x^3 + \Delta_2 x^2 + \Delta_3 x + \Delta_4 y - \Delta y^2 = pz, \quad (x, y, z) \in \mathbb{Z}^3.
\]

We can easily check that

\[
|\Delta_4| \ll (M/I)^6 M^2
\]

and

\[
|\Delta_j| \ll (M/I)^{2+j} M^3, \quad j = 1, 2, 3.
\]

Thus, collecting the above estimates and taking into account \(L \ll I\), we derive

\[
|z| \ll \frac{1}{p} (|\Delta_1|(M/L)^3 + |\Delta_2|(M/L)^2 + |\Delta_3|(M/L) + |\Delta_4|M + |\Delta|M^2)
\]

\[
\ll \frac{M^3}{p} \left( \frac{M^6}{I^3 L^3} + \frac{M^6}{I^4 L^2} + \frac{M^6}{I^5 L} + \frac{M^6}{I^6} \right) \ll \frac{M^9}{p I^3 L^3}.
\]

Since \(\Delta_1 \neq 0\) and \(\Delta \neq 0\), for each \(z\), the curve (17) is absolutely irreducible, and thus by Lemma 12 it contains at most \(M^{1/3+o(1)}\) integer points \((x, y)\) with \(|x|, |y| \leq M\). Hence,

\[
\frac{I}{L} \leq M^{1/3+o(1)} \left( 1 + \frac{M^9}{p I^3 L^3} \right)
\]

for any \(L\) satisfying (13). This implies that

\[
I \leq LM^{1/3+o(1)} \frac{M^{7/3+o(1)}}{p^{1/4} L^{1/2}}.
\]

(18)
If \( M < 10p^{1/8} \), then we take \( L = 1 \) and derive from (18) that
\[
I \leq M^{1/3+o(1)} + \frac{M^{7/3+o(1)}}{p^{1/4}} \leq M^{1/3+o(1)}.
\]

Let now \( M > 10p^{1/8} \). We can assume that \( I > M^{5/3}p^{-1/6} \) since otherwise there is nothing to prove. Then we take \( L = \lfloor M^{4/3}p^{-1/6} \rfloor \) and note that condition (13) is satisfied. Thus, we derive from (18) that
\[
I \leq LM^{1/3+o(1)} + \frac{M^{7/3+o(1)}}{p^{1/4}L^{1/2}} \leq M^{5/3+o(1)}p^{-1/6},
\]
and the result follows.

### 5.2. Proof of Theorem 2

Clearly we can assume that
\[
M > p^{5/23}
\]
(19)
since otherwise
\[
(M^3/p)^{1/16} M \geq \frac{M^{5/3+o(1)}}{p^{1/6}},
\]
and the result follows from Theorem 1. We can also assume that \( M = o(p^{1/3}) \).

We fix one solution \((x_0, y_0)\) to the congruence (1), and by making the change of variables \((x, y) \mapsto (x - x_0, y - y_0)\) we see that it is enough to study a congruence of the form
\[
y^2 - c_0 y \equiv c_3 x^3 + c_2 x^2 + c_1 x \pmod p, \quad |x|, |y| \leq M.
\]
(20)
Let \( \mathcal{W} \) be the set of pairs \((x, y)\) that satisfy (20), and let \( \mathcal{X} \) denote the set of \( x \) for which \((x, y) \in \mathcal{W}\) for some \( y \). Let
\[
\rho = \frac{\#\mathcal{X}}{M}.
\]

We now fix some \( \varepsilon > 0 \) and assume that
\[
\rho \geq (M^3/p)^{1/16} M^\varepsilon.
\]
(21)
We also assume that \( M \) is sufficiently large. In view of (19) and (21), we also have
\[
\rho > M^{-1/10}.
\]
(22)
For \( \theta > 0 \), we define the intervals
\[
I_{\nu, \theta} = [-\theta M^\nu, \theta M^\nu], \quad \nu = 1, 2, 3,
\]
which we treat as intervals in \( \mathbb{F}_p \), that is, sets of residues modulo \( p \) of several consecutive integers.

We now consider the set
\[
\mathcal{S} \subseteq I_{1,8} \times I_{2,8} \times I_{3,8}
\]
of all triples
\[
s \equiv (x_1 + \cdots + x_8, x_1^2 + \cdots + x_8^2, x_1^3 + \cdots + x_8^3) \pmod p,
\]
(23)
where \( x_i, i = 1, \ldots, 8 \), independently run through the set \( \mathcal{X} \). We observe that the system of congruences
\[
x_1^j + \cdots + x_8^j \equiv x_9^j + \cdots + x_{16}^j \pmod{p}, \quad j = 1, 2, 3,
\]
has at most \( M^{10+o(1)} \) solutions in integers \( x_i, y_i \) with \( |x_i|, |y_i| \leq M \). Indeed, since \( M = o(p^{1/3}) \), the above congruence is converted to the system of Diophantine equations
\[
x_1^j + \cdots + x_8^j = x_9^j + \cdots + x_{16}^j, \quad j = 1, 2, 3,
\]
which by Lemma 13 has at most \( M^{10+o(1)} \) solutions in integers \( x_i \) with \( |x_i| \leq M \), \( i = 1, \ldots, 16 \). Therefore, the congruence (24) has at most \( M^{10+o(1)} \) solutions in \( x_i \in \mathcal{X}, i = 1, \ldots, 16 \), as well. Thus, collecting the elements of the set \( \mathcal{X}^8 \) that correspond to the same vector \( s \) given by (23) and denoting the number of such representations by \( N(s) \), by the Cauchy inequality we obtain
\[
(\#\mathcal{X})^8 = \sum_{s \in S} N(s) \leq \left( \sum_{s \in S} N(s)^2 \right)^{1/2} \leq (\#S M^{10+o(1)})^{1/2}.
\]
Thus,
\[
\#S \geq \frac{(\#\mathcal{X})^{16}}{M^{10+o(1)}} = \rho^{16} M^{6+o(1)}.
\]
Hence, there exist at least \( \rho^{16} M^{6+o(1)} \) triples
\[
(z_1, z_2, z_3) \in I_{1,8} \times I_{2,8} \times I_{3,8}
\]
such that
\[
c_3 z_3 + c_2 z_2 + c_1 z_1 \equiv \tilde{z}_2 - c_0 \tilde{z}_1 \pmod{p}
\]
for some \( \tilde{z}_2 \in I_{2,8} \) and \( \tilde{z}_1 \in I_{1,8} \). In particular, we have that the congruence
\[
c_3 z_3 + c_2 z_2 + \tilde{z}_2 + c_1 z_1 + c_0 \tilde{z}_1 \equiv 0 \pmod{p},
\]
\[
(z_1, \tilde{z}_1, z_2, \tilde{z}_2, z_3) \in I_{1,8} \times I_{1,8} \times I_{2,8} \times I_{2,8} \times I_{3,8},
\]
has a set of solutions \( S \) with
\[
\#S \geq \rho^{16} M^{6+o(1)}. \tag{25}
\]

The rest of the proof is based on the ideas from [7].

We define the lattice
\[
\Gamma = \{(X_2, X_3, \tilde{X}_2, X_1, \tilde{X}_1) \in \mathbb{Z}^5 : \quad X_2 + c_3 X_3 + c_2 \tilde{X}_2 + c_1 X_1 + c_0 \tilde{X}_1 \equiv 0 \pmod{p}\}
\]
and the body
\[
D = \{(x_2, x_3, \tilde{x}_2, x_1, \tilde{x}_1) \in \mathbb{R}^5 : \quad |x_1|, |\tilde{x}_1| \leq 8M, |x_2|, |\tilde{x}_2| \leq 8M^2, |x_3| \leq 8M^3\}.
\]
We see from (25) that
\[
(\#(D \cap \Gamma) \geq \rho^{16} M^{6+o(1)}.
\]
Therefore, by Corollary 17, the successive minima $\lambda_i = \lambda_i(D, \Gamma)$, $i = 1, \ldots, 5$, satisfy the inequality
\[
\prod_{i=1}^{5} \min\{1, \lambda_i\} \ll \rho^{-16} M^{-6+o(1)}.
\] (26)

From the definition of $\lambda_i$ it follows that there are five linearly independent vectors
\[
v_i = (v_{2,i}, v_{3,i}, \tilde{v}_{2,i}, v_{1,i}, \tilde{v}_{1,i}) \in \lambda_i D \cap \Gamma, \quad i = 1, \ldots, 5.
\] (27)

Indeed, we first choose a nonzero vector $v_1 \in \lambda_1 D \cap \Gamma$. Then assuming that, for $1 \leq i \leq 5$, the vectors $v_1, \ldots, v_{i-1}$ are chosen, we choose $v_i$ as one of the vectors $\lambda_i D \cap \Gamma$ that are not in the linear space generated by $v_1, \ldots, v_{i-1}$.

We now note that
\[
\lambda_3 < 1.
\]
Indeed, otherwise from (26) we obtain
\[
\min\{1, \lambda_2^2\} \leq \min\{1, \lambda_1\} \min\{1, \lambda_2\} \leq \rho^{-16} M^{-6+o(1)}.
\]

Thus, recalling (22), we see that
\[
\lambda_1 \leq \frac{1}{10M^2}.
\]
Then the vector $v_1$ must have $v_{2,1} = \tilde{v}_{2,1} = v_{1,1} = \tilde{v}_{1,1} = 0$. In turn, this implies that $v_{3,1} \equiv 0 \pmod{p}$, and since we assumed that $M = o(p^{1/3})$, we obtain $v_{3,1} = 0$, which contradicts the condition that $v_1$ is a nonzero vector.

We consider separately the following four cases.

**Case 1:** $\lambda_5 \leq 1$. Then by (26) we have
\[
\prod_{i=1}^{5} \lambda_i \leq \rho^{-16} M^{-6+o(1)}.
\]

We now consider the determinant $\Delta$ of the $5 \times 5$ matrix that is formed by the vectors (27). It follows that
\[
\Delta \ll M^{2+3+2+1+1} \prod_{i=1}^{5} \lambda_i \leq \rho^{-16} M^{3+o(1)},
\]
which, by our assumption (21), implies that $|\Delta| < p$. On the other hand, since $v_i \in \Gamma$, we have $\Delta \equiv 0 \pmod{p}$; thus, $\Delta = 0$, provided that $p$ is large enough, which contradicts the linear independence of the vectors in (27). Thus, this case is impossible.

**Case 2:** $\lambda_4 \leq 1, \lambda_5 > 1$. Let
\[
V = \begin{pmatrix}
v_{3,1} & \tilde{v}_{2,1} & v_{1,1} & \tilde{v}_{1,1} \\
v_{3,2} & v_{2,2} & v_{1,2} & \tilde{v}_{1,2} \\
v_{3,3} & \tilde{v}_{2,3} & v_{1,3} & \tilde{v}_{1,3} \\
v_{3,4} & \tilde{v}_{2,4} & v_{1,4} & \tilde{v}_{1,4}
\end{pmatrix}, \quad W = \begin{pmatrix}
-v_{2,1} \\
v_{2,2} \\
v_{2,3} \\
v_{2,4}
\end{pmatrix}, \quad C = \begin{pmatrix}
c_3 \\
c_2 \\
c_1 \\
c_0
\end{pmatrix}.
We have
\[ Vc \equiv w \pmod{p}. \]

Let
\[ \Delta = \det V, \]
and let \( \Delta_j \) be the determinant of the matrix obtained by replacing the \( j \)th column of \( V \) by \( w \), \( j = 1, \ldots, 4 \).

Recalling (26), we have
\[ |\Delta| \ll \lambda_1 \lambda_2 \lambda_3 \lambda_4 M^3 + 2 + 1 + 1 \leq \rho^{-16} M^{1+o(1)} \] (28)
and, similarly,
\[ |\Delta_1| \leq \rho^{-16} M^{o(1)}, \]
\[ |\Delta_2| \leq \rho^{-16} M^{1+o(1)}, \]
\[ |\Delta_3| \leq \rho^{-16} M^{2+o(1)}, \]
\[ |\Delta_4| \leq \rho^{-16} M^{2+o(1)}. \] (29)

Note that, in view of (21), in particular, we have
\[ |\Delta|, |\Delta_j| < p, \quad j = 1, \ldots, 4. \]

If \( \Delta \equiv 0 \pmod{p} \), then since \( c \) is nonzero modulo \( p \), we also have \( \Delta_j \equiv 0 \pmod{p} \), \( j = 1, \ldots, 4 \), implying that \( \Delta = \Delta_j = 0 \) (in fact, this holds regardless whether \( c \) is zero or not modulo \( p \)). Then the matrix formed by \( v_1, \ldots, v_4 \) is of rank at most 3, which contradicts their linear independence. Therefore, \( \Delta \not\equiv 0 \pmod{p} \), and thus we have
\[ c_i \equiv \frac{\Delta_{4-i}}{\Delta} \pmod{p}, \quad i = 0, 1, 2, 3. \]

Since \( c_3 \not\equiv 0 \pmod{p} \), we have \( \Delta_1 \not\equiv 0 \). We now substitute this into (20) and get that
\[ \Delta y^2 - \Delta_4 y \equiv \Delta_1 x^3 + \Delta_2 x^2 + \Delta_3 x \pmod{p}, \quad |x|, |y| \leq M. \]

We see from (21), (28), and (29) that for sufficiently large \( M \), the absolute values of the expressions on both sides are less than \( p/2 \), implying the equality
\[ \Delta y^2 - \Delta_4 y = \Delta_1 x^3 + \Delta_2 x^2 + \Delta_3 x, \quad |x|, |y| \leq M. \]

Now we use Lemma 12 and conclude that the number of solutions is at most \( M^{1/3 + o(1)} \).

**Case 3:** \( \lambda_3 \leq (10M)^{-1}, \lambda_4 > 1 \). By (26) we have
\[ \prod_{i=1}^{3} \lambda_i \leq \rho^{-16} M^{6 + o(1)}. \]

Since \( \lambda_3 \leq (10M)^{-1} \), we also have
\[ v_i = (v_{2,i}, v_{3,i}, \tilde{v}_{2,i}, 0, 0), \quad i = 1, 2, 3. \] (30)

In particular,
\[ \begin{pmatrix} v_{2,1} & v_{3,1} & \tilde{v}_{2,1} \\ v_{2,2} & v_{3,2} & \tilde{v}_{2,2} \\ v_{2,3} & v_{3,3} & \tilde{v}_{2,3} \end{pmatrix} \begin{pmatrix} 1 \\ c_3 \\ c_2 \end{pmatrix} \equiv \begin{pmatrix} 0 \\ 0 \end{pmatrix} \pmod{p}. \]
Thus, for the determinant
\[
\Delta = \det \begin{pmatrix}
v_{2,1} & v_{3,1} & \tilde{v}_{2,1} \\
v_{2,2} & v_{3,2} & \tilde{v}_{2,2} \\
v_{2,3} & v_{3,3} & \tilde{v}_{2,3}
\end{pmatrix},
\]
we have
\[
\Delta \equiv 0 \pmod{p}.
\]
On the other hand, from (22) we derive that
\[
|\Delta| \ll \lambda_1^2 \lambda_2 \lambda_3 M^7 < \frac{M^{1+o(1)}}{\rho^{16}} < M^{2.6+o(1)}.
\]
Hence, \(\Delta = 0\), which together with (30) implies that the vectors \(v_1, v_2, v_3\) are linearly dependent, which is impossible.

Case 4: \((10M)^{-1} < \lambda_3 \leq 1, \lambda_4 > 1\). By (26) we have
\[
\prod_{i=1}^{3} \lambda_i \leq \rho^{-16} M^{-6+o(1)},
\]
and since \(\lambda_3 > (10M)^{-1}\), we obtain
\[
\lambda_1 \lambda_2 < \rho^{-16} M^{-5+o(1)}.
\]
We again note that \(\lambda_1 > (10M^2)^{-1}\) since otherwise \(v_1\) should have \(v_{2,1} = \tilde{v}_{2,1} = v_{1,1} = \tilde{v}_{1,1} = 0\). In turn, this implies that \(v_{3,1} \equiv 0 \pmod{p}\), and since we assumed that \(M = o(p^{1/3})\), we obtain \(v_{3,1} = 0\), which contradicts the condition that \(v_1\) is a nonzero vector.

Since \(\lambda_1 > (10M^2)^{-1}\) and \(\rho > M^{-1/10}\), we get that \(\lambda_2 < (10M)^{-1}\). Thus, we have
\[
v_i = (v_{2,i}, v_{3,i}, \tilde{v}_{2,i}, 0, 0), \quad i = 1, 2.
\]
Next,
\[
\begin{pmatrix}
v_{3,1} & \tilde{v}_{2,1} \\
v_{3,2} & \tilde{v}_{2,2}
\end{pmatrix}
\begin{pmatrix}
c_3 \\
c_2
\end{pmatrix}
\equiv
\begin{pmatrix}
-v_{2,1} \\
-v_{2,2}
\end{pmatrix} \pmod{p}.
\]
Now we observe that
\[
\Delta = \det \begin{pmatrix}
v_{3,1} & \tilde{v}_{2,1} \\
v_{3,2} & \tilde{v}_{2,2}
\end{pmatrix} \ll \lambda_1 \lambda_2 M^5 < \frac{M^{o(1)}}{\rho^{16}}. \tag{31}
\]
Furthermore,
\[
\Delta_1 = \det \begin{pmatrix}
-v_{2,1} & \tilde{v}_{2,1} \\
-v_{2,2} & \tilde{v}_{2,2}
\end{pmatrix} \ll \lambda_1 \lambda_2 M^4 < \frac{M^{-1+o(1)}}{\rho^{16}}, \tag{32}
\]
and
\[
\Delta_2 = \det \begin{pmatrix}
v_{3,1} & -v_{2,1} \\
v_{3,2} & -v_{2,2}
\end{pmatrix} \ll \lambda_1 \lambda_2 M^5 < \frac{M^{o(1)}}{\rho^{16}}. \tag{33}
\]
In particular, \(|\Delta|, |\Delta_1|, |\Delta_2| < p\). Therefore, if \(\Delta \equiv 0 \pmod{p}\), then \(\Delta_1 \equiv \Delta_2 \equiv 0 \pmod{p}\), and we see that \(\Delta = \Delta_1 = \Delta_2 = 0\). Thus, in this case, the rank of
the matrix formed by vectors \( \mathbf{v}_1, \mathbf{v}_2 \) is at most 1, which contradicts the linear independence of the vectors \( \mathbf{v}_1, \mathbf{v}_2 \).

Hence, \( \Delta \not\equiv 0 \pmod{p} \), and we get that
\[
c_3 \equiv \frac{\Delta_1}{\Delta} \pmod{p}, \quad c_2 \equiv \frac{\Delta_2}{\Delta} \pmod{p}.
\]

We now substitute this into (20) and get that
\[
\Delta y^2 - a_0 y \equiv \Delta_1 x^3 + \Delta_2 x^2 + b_0 x \pmod{p}, \quad |x|, |y| \leq M,
\]
for some integers \( a_0, b_0 \). We observe that the condition \( c_3 \not\equiv 0 \pmod{p} \) implies that \( \Delta_1 \neq 0 \).

Let now
\[
T = \left\lfloor \left( \frac{p}{M} \right)^{1/3} \rho^{16/3} \right\rfloor.
\]
Note that \( M^{2/3} < T < T^2 < p/2 \). By the pigeonhole principle there exists a positive integer \( 1 \leq t_0 \leq T^2 + 1 \) such that
\[
|(t_0 a_0)_p| \leq \frac{p}{T}, \quad |(t_0 b_0)_p| \leq \frac{p}{T},
\]
where \( (x)_p \) is the element of the residue class \( x \pmod{p} \) with the least absolute value; see also [14, Lemma 3.2]. Hence,
\[
t_0 \Delta y^2 - (t_0 a_0)_p y \equiv t_0 \Delta_1 x^3 + t_0 \Delta_2 x^2 + (t_0 b_0)_p x \pmod{p}, \quad |x|, |y| \leq M.
\]
By (31), (32), and (33) the absolute values of the expressions on both sides are bounded by \( pM^{1+o(1)} T^{-1} \). Thus, we get
\[
t_0 \Delta y^2 - (t_0 a_0)_p y = t_0 \Delta_1 x^3 + t_0 \Delta_2 x^2 + (t_0 b_0)_p x + p z,
\]
where
\[
|x|, |y| \leq M, \quad |z| < M^{1+o(1)} T^{-1}.
\]
Now we use Lemma 12 and conclude that the number of solutions is at most
\[
\left( \frac{M}{T} + 1 \right) M^{1/3+o(1)} < \left( \frac{M^{4/3}}{p^{1/3}} \rho^{-16/3} + 1 \right) M^{1/3+o(1)} < M^{2/3+o(1)} < \left( \frac{M^{3}}{p} \right)^{1/16} M.
\]

Since \( \varepsilon > 0 \) is arbitrary, the result now follows.

5.3. Proof of Theorem 4

Let \( \mathcal{X} \) be the set of integers \( x \in [R + 1, R + M] \) such that the congruence (1) is satisfied for some integer \( y \in [S + 1, S + M] \). In particular, letting \( X = \#\mathcal{X} \), we have
\[
I_f(M; R, S) \leq 2X. \tag{34}
\]

Fix some integer \( k \geq 1 \) and consider the set
\[
\mathcal{Y}_k = \{ y_1^2 + \cdots + y_k^2 \pmod{p} : \ |y_i| \leq S+1, 1 \leq i \leq k \}.
\]
By making the change of variables \( y_i = S + z_i, \ i = 1, \ldots, k \), we observe that
\[
\mathcal{Y}_k = \{ z_1^2 + \cdots + z_k^2 + 2S(z_1 + \cdots + z_k) + kS^2 \pmod{p} : 1 \leq z_i \leq M, \ i = 1, \ldots, k \}.
\]
In particular,
\[
\#\mathcal{Y}_k \leq \#\{ r + 2Ts + kS^2 : 1 \leq r \leq kM^2, 1 \leq s \leq kM \} \leq k^2M^3.
\]
For any \((x_1, \ldots, x_k) \in X^k\), there exists \( \lambda \in \mathcal{Y}_k \) such that
\[
f(x_1) + \cdots + f(x_k) \equiv \lambda \pmod{p}.
\]
Thus,
\[
X^k \leq \sum_{\lambda \in \mathcal{Y}_k} r(\lambda),
\]
where
\[
r(\lambda) = \#\{(x_1, \ldots, x_k) \in [R + 1, R + M]^k : f(x_1) + \cdots + f(x_k) \equiv \lambda \pmod{p}\}.
\]
Using the Cauchy inequality, we derive
\[
X^{2k} \leq \#\mathcal{Y}_k \sum_{\lambda \in \mathcal{Y}_k} r^2(\lambda) \leq k^2M^3T_k(R, M),
\]
where \( T_k(R; M) \) is the number of solutions of
\[
f(x_1) + \cdots + f(x_k) \equiv f(x_{k+1}) + \cdots + f(x_{2k}) \pmod{p},
\]
\((x_1, \ldots, x_{2k}) \in [R + 1, R + M]^{2k}\).

The quantity \( T_k(R; M) \) has been defined and estimated in [13] for \( R = 0 \), but making a change of variables, it is clear that the same bound holds for any \( R \). In particular, it is proved in [13] that
\[
T_k(R; M) \ll (M^m/p + 1)M^{m(m-1)/2}J_{k,m}(M),
\]
where, as before, \( J_{k,m}(M) \) is the number of solutions of the system of equations (4) with \( H = M \).

Taking \( k = \kappa(m) \) so that the bound (5) holds, we derive
\[
X^{2k} \leq M^3(M^m/p + 1)M^{m(m-1)/2}M^{2k-m(m+1)/2+o(1)}
\leq (M^m/p + 1)M^{2k+3m+o(1)}
\]
and obtain
\[
X \leq M(M^3/p)^{1/2\kappa+o(1)} + M^{1-(m-3)/2\kappa+o(1)},
\]
which together with (34) concludes the proof.
5.4. Proof of Theorem 5

Let \( J = J_f(M; R, S) \).

Without loss of generality we can assume that

\[
0 \leq M + 1 < M + S < p.
\]

Applying Lemma 10 to the sequence of fractional parts \( \gamma_n = \{f(n)/p\} \), \( n = 1, \ldots, M \), with

\[
\alpha = (S + 1)/p, \quad \beta = (S + M + 1)/p, \quad K = \lfloor p/M \rfloor,
\]

so that we have

\[
\frac{1}{K} + \min\{\beta - \alpha, 1/k\} \ll \frac{M}{p}
\]

for \( k = 1, \ldots, K \), we derive

\[
J \ll \frac{M^2}{p} + \frac{M}{p} \sum_{k=1}^{K} \sum_{n=1}^{M} \exp(2\pi i k f(n)/p).
\]

Therefore, by Lemma 11 we have

\[
J \ll \frac{M^2}{p} + \frac{M^{2-m/2^{m-1}}}{p} K(M^{m-1})^{2^{1-m}} + \frac{M^{2-m/2^{m-1}}}{p} W,
\]

where \( a \) is the leading coefficient of \( f \). Now, separating the contribution from the terms with \( \ell_1 \cdots \ell_{m-1} = 0 \), we obtain

\[
J \ll \frac{M^2}{p} + \frac{M^{2-m/2^{m-1}}}{p} K(M^{m-1})^{2^{1-m}} + \frac{M^{2-m/2^{m-1}}}{p} W,
\]

where

\[
W = \sum_{k=1}^{K} \left( \sum_{0 < |\ell_1|, \ldots, |\ell_{m-1}| < M} \min\left\{ M, \frac{a}{p} m! k \ell_1 \cdots \ell_{m-1} \right\}^{-1} \right)^{2^{1-m}}.
\]

Hence, recalling the choice of \( K \), we derive

\[
J \ll \frac{M^2}{p} + M^{1-1/2^{m-1}} + \frac{M^{2-m/2^{m-1}}}{p} W. \tag{35}
\]

The Hölder inequality implies the bound

\[
W^{2^{m-1}} \ll K^{2^{m-1} - 1} \times \sum_{k=1}^{K} \sum_{0 < |\ell_1|, \ldots, |\ell_{m-1}| < M} \min\left\{ M, \frac{a}{p} m! k \ell_1 \cdots \ell_{m-1} \right\}^{-1}.
\]

Collecting together the terms with the same value of

\[
z = m! k \ell_1 \cdots \ell_{m-1} \not\equiv 0 \pmod{p}
\]
and recalling the well-known bound on the divisor function, we conclude that

\[ W^{2m-1} \ll K^{2m-1-1} p^{o(1)} \sum_{|z| < m/2} \min \left\{ M, \left\| \frac{a}{z} \right\|^{-1} \right\}. \]

Since the sequence \( \|am/p\| \) is periodic with period \( p \), we see that

\[ W^{2m-1} \ll K^{2m-1-1} p^{o(1)} \sum_{z=1}^{p-1} \left\| \frac{z}{p} \right\|^{-1} \ll K^{2m-1} M^{m-1} p^{o(1)}. \]

Thus, recalling the choice of \( K \), we derive

\[ W \leq K M^{(m-1)/2^{m-1}} p^{o(1)} \leq M^{(m-1)/2^{m-1}-1} p^{1+o(1)}, \]

which, after substitution into (35), concludes the proof.

### 5.5. Proof of Theorem 6

Assume that \( H = H_b \) for some vector \( b = (b_0, \ldots, b_{2g-1}) \in \mathbb{F}_p^{2g} \). We recall that all components of any vector \( a \in \mathcal{A} \) are nonzero modulo \( p \). Hence, \( b_0 \in \mathbb{F}_p^* \), and we see from (6) (combining the equations with \( i = 2g + 1 - h \) and \( i = 2g - 1 \)) that

\[ a_{2g-1}^h \equiv \lambda a_{2g+1-h}^2 \pmod{p}, \]
\[ R_{2g+1-h} + 1 \leq a_{2g+1-h} \leq R_{2g+1-h} + M, \]
\[ R_{2g-1} + 1 \leq a_{2g-1} \leq R_{2g-1} + M, \]

where

\[ \lambda = b_{2g-1}^h / b_{2g+1-h}^2. \]  \( \text{(37)} \)

We also observe that

\[ \alpha^4 = b_{2g-1}^h / a_{2g-1}. \]

Thus, each solution \((a_{g+1-h}, a_{2g-1})\) of (36) determines at most two values of \( \alpha^2 \), each of which in turn determines all other values of \( a_0, a_1, \ldots, a_{2g-1} \).

Thus, we have seen that \( N(H; \mathcal{A}) \leq 2T \), where \( T \) is the number of solutions \((x, y)\) of the congruence

\[ x^h \equiv \lambda y^2 \pmod{p}, \quad R + 1 \leq x \leq R + M, \quad S + 1 \leq y \leq S + M, \]

where \( R = R_{g+1-h}, S = R_{2g-1}, \) and \( \lambda \) is given by (37).

We now observe that the congruence (38) taken with \( h = 4 \), which is admissible for \( g \geq 2 \), implies

\[ x^2 \equiv \mu y \pmod{p}, \quad R + 1 \leq x \leq R + M, \quad S + 1 \leq y \leq S + M, \]
where \( \mu \) is one of the two square roots of \( \lambda \) (we recall that \( g \geq 2 \)). Applying Theorem 5 for \( M > p^{2/7} \) and also (9) for \( M \leq p^{2/7} \) with a quadratic polynomial \( f \), we immediately obtain the desired result.

5.6. Proof of Theorem 7

As in the proof of Theorem 6, we let \( H = H_b \) for some \( b = (b_0, \ldots, b_{2g-1}) \in \mathbb{F}_p^{2g} \).

We can assume that \( M < p^{1/4} \) since otherwise the results are weaker than the trivial upper bound \( N(H; \mathcal{B}) \ll M \).

Let \( T \) be the number of solutions \((x, y)\) to the congruence (38). We follow the proof of Theorem 1. We can assume that \( T \) is sufficiently large (recall that \( g \) is a fixed integer constant). We fix some integer \( L \) with

\[
1 \leq L \leq \frac{T}{12(h + 1)},
\]

(39)
to be chosen later. Thus, there exists \( Q \) such that the congruence

\[
x^h \equiv \lambda y^2 \pmod{p}, \quad Q + 1 \leq x \leq Q + M/L, S + 1 \leq y \leq S + M,
\]

has at least \( T/L \) solutions. We can split the interval \([Q + 1, Q + M/L]\) into \( k_0 = \lceil T/(6(h + 1)L) \rceil \) intervals of length at most \( 6(h + 1)M/T \). Since there are at most two solutions to the above congruence with the same value of \( x \), and since we have at least \( T/L > 4(h + 1)k_0 \) solutions in total, from the pigeonhole principle it follows that there exists an interval of length \( 6(h + 1)M/T \) containing at least \( 2(h + 1) \) pairwise distinct values of \( x \). Let \( x_0 \) be the first of these values, and \((x_0, y_0)\) the solution. It is clear that \( T/L \) is bounded by the number of solutions of

\[
(x_0 + x)^h \equiv \lambda(y_0 + y)^2 \pmod{p},
\]

\[-M/L \leq x \leq M/L, -M \leq y \leq M,
\]

which is equivalent to

\[
c_h x^h + \cdots + c_1 x + c_0 y \equiv y^2 \pmod{p},
\]

\[-M/L \leq x \leq M/L, -M \leq y \leq M,
\]

(40)

where

\[
c_0 = -2y_0 \quad \text{and} \quad c_j = \lambda^* \binom{h}{j} x_0^{h-j}, \quad j = 1, \ldots, h,
\]

with \( \lambda^* \) defined by \( \lambda^* \lambda \equiv 1 \pmod{p} \) and \( 1 \leq \lambda^* < p \). In particular, \( c_h \not\equiv 0 \pmod{p} \). Besides, there are at least \( 2h + 1 \) solutions \((x, y)\) of (40) with pairwise distinct \( x \) and such that \( 1 \leq x \leq 6(h + 1)M/T \). From these \( 2h + 1 \) values we fix \( h: (x_1, y_1), \ldots, (x_h, y_h) \) and rewrite (40) in the form

\[
\begin{pmatrix}
  x^h & \ldots & x & y \\
  x_h & \ldots & x_h & y_h \\
  \vdots \\
  x_1 & \ldots & x_1 & y_1
\end{pmatrix}
\begin{pmatrix}
  c_h \\
  \cdots \\
  c_1 \\
  c_0
\end{pmatrix}
\equiv
\begin{pmatrix}
  y^2 \\
  y_h^2 \\
  \cdots \\
  y_1^2
\end{pmatrix} \pmod{p}.
\]

(41)
Since \( h \) is odd, by Lemma 14, we know that at most \( 2^h \) pairs \((x, y)\), with pairwise distinct \( x \), satisfy both the congruence (41) and the congruence
\[
\begin{vmatrix}
x^h & \ldots & x & y \\
x_h & \ldots & x_h & y_h \\
\vdots \\
x_1^h & \ldots & x_1 & y_1 \\
\end{vmatrix} \equiv 0 \pmod{p}.
\]
Since there are at least \( 2^{h+1} \) solutions of (41), for one of them, say \((x_h+1, y_h+1)\), we have
\[
\Delta = \begin{vmatrix}
x_h^{h+1} & \ldots & x_{h+1} & y_{h+1} \\
x_h^h & \ldots & x_h & y_h \\
\vdots \\
x_1^h & \ldots & x_1 & y_1 \\
\end{vmatrix} \neq 0 \pmod{p}.
\]
Note that \( 1 \leq |\Delta| \ll (M/T)^{h(h+1)/2}M \). Now we solve the system
\[
\begin{pmatrix}
x_h^{h+1} & \ldots & x_{h+1} & y_{h+1} \\
x_h^h & \ldots & x_h & y_h \\
\vdots \\
x_1^h & \ldots & x_1 & y_1 \\
\end{pmatrix}
\begin{pmatrix}
c_h \\
c_{h-1} \\
\vdots \\
c_0 \\
\end{pmatrix}
= \begin{pmatrix}
y_{h+1}^2 \\
y_h^2 \\
\vdots \\
y_1^2 \\
\end{pmatrix} \pmod{p} \tag{42}
\]
with respect to \((c_h, \ldots, c_1, c_0)\). We write \( \Delta_j \) for the determinant of the matrix on the left-hand side where we have substituted the column \( j \) by the vector \((y_{h+1}^2, \ldots, y_1^2)\). With this notation we have that
\[
c_j = \frac{\Delta_{h+1-j}}{\Delta}, \quad j = 0, \ldots, h,
\]
and the congruence (40) is equivalent to
\[
\Delta_1 x^h + \Delta_2 x^{h-1} + \cdots + \Delta_h x + \Delta_{h+1} y - \Delta y^2 \equiv 0 \pmod{p}.
\]
In particular, \( \Delta_1 \not\equiv 0 \pmod{p} \). We can write this congruence as an equation over \( \mathbb{Z} \):
\[
\Delta_1 x^h + \Delta_2 x^{h-1} + \cdots + \Delta_h x + \Delta_{h+1} y - \Delta y^2 = pz, \quad z \in \mathbb{Z}. \tag{43}
\]
We can easily check that
\[
|\Delta_{h+1}| \ll (M/T)^{h(h+1)/2}M^2
\]
and
\[
|\Delta_j| \ll (M/T)^{h(h-1)/2+j-1}M^3, \quad j = 1, \ldots, h.
\]
Thus, collecting the above estimates, we derive
\[
|z| \ll \frac{1}{p} \left( \sum_{j=1}^h |\Delta_j|(M/L)^{h-j+1} + |\Delta_{h+1}|M + |\Delta|M^2 \right)
\ll \frac{M^3}{p} \left( \sum_{j=1}^h (M/T)^{h(h-1)/2+j-1}(M/L)^{h-j+1} + (M/T)^{h(h+1)/2} \right)
\]
\[
\ll \frac{M^3}{p} \left( M^{h+1/2}T^{-h(h-1)/2}L^{-h} \sum_{j=1}^{h} (T/L)^{-j+1} + (M/T)^{h(h+1)/2} \right)
\ll \frac{M^{h+1/2+3}}{pT^{h(h-1)/2}L^h}
\]
since by (39) we have
\[
\sum_{j=1}^{h} (T/L)^{-j+1} = O(1) \quad \text{and} \quad (M/T)^{h(h+1)/2} \leq \frac{M^{h+1/2}}{T^{h(h-1)/2}L^h}.
\]

Since \( h \) is odd and \( \Delta \neq 0, \Delta_1 \neq 0 \), we have that, for each \( z \), the curve (43) is absolutely irreducible. Thus, by Lemma 12 it contains at most \( M^{1/h+o(1)} \) integer points \((x, y)\) with \(|x|, |y| \leq M\). Hence,
\[
T \leq LM^{1/h+o(1)} \left( 1 + \frac{M^{h+1/2+3}}{pT^{h(h-1)/2}L^h} \right)
\]
for any \( L \) satisfying (39).

We can assume that the following lower bounds hold for \( T \):
\[
T > M^{1/h} \quad \text{and} \quad T > 24(h+1)(M^4/p)^{2/h(h+1)} + 1
\]
since otherwise there is nothing to prove.

Take \( L = \lfloor 1 + (M^{(h^2+7)/2}/p)^{2/h(h+1)} \rfloor \). We note that (39) holds since otherwise \( L \geq 2 \) and we should have
\[
\left( \frac{M^{(h^2+7)/2}}{p} \right)^{2/h(h+1)} \geq L - 1 \geq \frac{L}{2} > \frac{T}{24(h+1)} > M \left( \frac{M^4}{p} \right)^{2/h(h+1)} \left( \frac{M^{h+1/2+3}}{p} \right)^{2/h(h+1)},
\]
which is impossible.

If \( M < p^{2/(h^2+7)} \), then we have \( L = 1 \) and, in view of (45), also
\[
\frac{M^{h+1/2+3}}{pT^{h(h-1)/2}L^h} \leq \frac{M^{h+1/2+3}}{pM^{h-1/2}} = \frac{M^{(h^2+7)/2}}{p} < 1.
\]
In this case, the bound (44) yields
\[
T \ll M^{1/h+o(1)}.
\]
If \( M \geq p^{2/(h^2+7)} \), then we have
\[
(M^{(h^2+7)/2}/p)^{2/h(h+1)} \ll L \ll (M^{(h^2+7)/2}/p)^{2/h(h+1)},
\]
and, recalling our assumption (45), we obtain
\[
\frac{M^{h+1/2+3}}{pT^{h(h-1)/2}L^h} \ll \frac{M^{h+1/2+3}}{pM^{h-1/2}(M^4/p)^{(h-1)/(h+1)}(M^{(h^2+7)/2}/p)^{2/(h+1)}} = 1.
\]
Hence, in this case we derive from (44) that
\[
T \leq (M^{(h^2+7)/2}/p)^{2/h(h+1)} M^{1/h+o(1)}
\]
\[
= M(M^4/p)^{2/h(h+1)+o(1)},
\]
which concludes the proof.

5.7. Proof of Theorem 8

Clearly,
\[
\sum_{H \in \mathcal{H}^{(\mathfrak{B})}} N(H; \mathfrak{B}) = M^{2g}.
\] (46)

We also set
\[
T(\mathfrak{B}) = \sum_{H \in \mathcal{H}(\mathfrak{B})} N(H; \mathfrak{B})^2.
\] (47)

As in [14], using (46), (47), and the Cauchy inequality, we derive
\[
\#\mathcal{H}(\mathfrak{B}) \geq M^{4g} T(\mathfrak{B})^{-1}.
\]

From (6) we observe that \( T(\mathfrak{B}) \) is the numbers of pairs of vectors \( \langle a, b \rangle \), \( a, b \in \mathfrak{B} \), such that there exists \( \alpha \) such that
\[
a_i \equiv \alpha^{4g+2-2i} b_i \pmod{p}, \quad i = 0, \ldots, 2g - 1.
\]

In particular,
\[
a_{2g-1}^3 b_{2g-2}^2 \equiv a_{2g-2}^2 b_{2g-1}^3 \pmod{p}.
\]

Now by Lemma 15 we see that there are only \( O(M^4/p + M^{2+o(1)}) \) possibilities for the quadruple \( \langle a_0, \ldots, a_{2g-3}, b_0, \ldots, b_{2g-3} \rangle \). Therefore,
\[
T(\mathfrak{B}) \leq M^{2g-2} (M^4/p + M^{2+o(1)}).
\] (48)

When \( M < p^{1/(2g)} \), we obtain \( T(\mathfrak{B}) \leq M^{2g+o(1)} \) and \( \#\mathcal{H}(\mathfrak{B}) \geq M^{2g+o(1)} \), which proves Theorem 8 in this range.

When \( M \geq p^{1/(2g)} \), we use a different approach. Using the notation
\[
N_i(\lambda) = \# \{ (a_i, b_i) : a_i/b_i \equiv \lambda \pmod{p}, R_i + 1 \leq a_i, b_i \leq R_i + M \},
\]
we can write
\[
T(\mathfrak{B}) = \sum_{\alpha=1}^{p-1} N_0(\alpha^{4g+2}) N_1(\alpha^{4g}) \cdots N_{2g-1}(\alpha^4).
\]

Thus,
\[
T^{2g}(\mathfrak{B}) \leq \left( \sum_{\alpha=1}^{p-1} N_0^{2g}(\alpha^{4g+2}) \right) \cdots \left( \sum_{\alpha \neq 0}^{p-1} N_{2g-1}^{2g}(\alpha^4) \right)
\]
\[
\leq \left( (4g + 2) \sum_{\alpha=1}^{p-1} N_0^{2g}(\alpha) \right) \cdots \left( 4 \sum_{\alpha=1}^{p-1} N_{2g-1}^{2g}(\alpha) \right).
and then we have

$$T(B) \ll \max_i \sum_{\alpha=1}^{p-1} N_i^{2g}(\alpha).$$

We observe that for any $\alpha \not\equiv 0 \pmod{p}$, there exist integers $r$, $s$ with $1 \leq |r|$, $s \leq p^{1/2}$, $(r, s) = 1$ and such that $\alpha \equiv r/s \pmod{p}$. Thus,

$$\sum_{\alpha=1}^{p-1} N_i^{2g}(\alpha) \leq \sum_{1 \leq r, s < p^{1/2}} \frac{N_i^{2g}(r/s)}{\gcd(r, s) = 1} + \sum_{1 \leq r, s < p^{1/2}} \frac{N_i^{2g}(-r/s)}{\gcd(r, s) = 1}.$$

Our estimate of $N_i(r/s)$ is based on an argument that is very close to that used in the proof of [2, Lemma 1]. Namely, we observe that $N_i(r/s)$ is the number of solutions $(x, y)$ to the congruence

$$x/y \equiv r/s \pmod{p}, \quad R_i + 1 \leq x, y \leq R_i + M,$$

which, after the change of variables, is equivalent to the congruence

$$sx - ry \equiv c \pmod{p}, \quad 1 \leq x, y \leq M,$$

for a suitable $c$. We can write the congruence as an equation in integers

$$sx - ry = c + zp, \quad 1 \leq x, y \leq M, \quad z \in \mathbb{Z}.$$

We observe that

$$|z| \leq \frac{|s|M + |r|M + |c|}{p} \leq \frac{(|s| + |r|)M}{p} + 1.$$

For each $z$, we consider, in case it has, a solution $(x_z, y_z), 1 \leq x_z, y_z \leq M$. The solutions of the Diophantine equation above is given by $(x, y) = (x_z + rt, y_z + st), t \in \mathbb{Z}$. The restriction $1 \leq x, y \leq M$ implies that $|t| \leq M/\max\{r, s\}$.

Thus, we have

$$N_i(r/s) \leq \left(1 + \frac{2M}{\max\{r, s\}}\right)\left(1 + \frac{2M(s + r)}{p}\right) \leq 1 + \frac{4M \max\{r, s\}}{p} \cdot \frac{2M}{\max\{r, s\}} + \frac{4M^2}{p}.$$

Therefore,

$$\sum_{1 \leq r, s < p^{1/2}} \frac{N_i^{2g}(r/s)}{\gcd(r, s) = 1} \ll \sum_{1 \leq r, s < p^{1/2}} \left(1 + \frac{M^{2g}(\max\{r, s\})^{2g}}{p^{2g}} + \frac{M^{2g}r^{2g}}{(\max\{r, s\})^{2g}} + \frac{M^{4g}}{p^{2g}}\right) \ll \sum_{1 \leq r, s < p^{1/2}} \left(1 + \frac{M^{2g}s^{2g}}{p^{2g}} + \frac{M^{2g}s^{2g}}{s^{2g}} + \frac{M^{4g}}{p^{2g}}\right).$$
The estimate of the sum with $N_{i}^{2g} (-r/s)$ is fully analogous. Assume that $M \geq p^{1/(2g)}$ and observe that

$$
\sum_{1 \leq s < p^{1/2}} \frac{1}{s^{2g-1}} \ll \begin{cases} 
\log M & \text{if } g = 1, \\
1 & \text{if } g \geq 2.
\end{cases}
$$

Thus, we have

$$
T(\mathcal{B}) \ll \begin{cases} 
M^2 \log M + M^4/p & \text{if } g = 1, \\
M^{2g} + M^{4g}/p^{2g-1} & \text{if } g \geq 2,
\end{cases}
$$

which gives

$$
\#H(\mathcal{B}) \geq M^{4g} T(\mathcal{B})^{-1} \gg \begin{cases} 
\min\{p, M^{2+o(1)}\} & \text{if } g = 1, \\
\min\{p^{2g-1}, M^{2g}\} & \text{if } g \geq 2,
\end{cases}
$$

and proves Theorem 8 in the range $M \geq p^{1/2}$.

6. Comments

The problem of obtaining a nontrivial upper bound for $I_{f}(M; R, S)$ in the range $p^{1/3} < M < p^{1/2}$ is still open.

On the other hand, we note that using bounds of exponential sums obtained with the method of Vinogradov instead of Lemma 11 (see [5; 16; 31; 38] and references therein) also leads to some nontrivial bounds on $J_{f}(M; R, S)$, but these results seem to be weaker than a combination of Theorem 5 with the bounds from [13].

Similar ideas can be exploited to obtain lower bounds for the cardinality of the set $\mathcal{I}(\mathcal{B})$ of nonisomorphic isogenous elliptic curves $H_{a}$ with coefficients in a cube $\mathcal{B}$.

Indeed, let us denote by $\mathcal{I}_{t}$ the isogeny class consisting of elliptic curves over $\mathbb{F}_{p}$ with the same number $p + 1 - t$ of $\mathbb{F}_{p}$-rational points. By a result of Deuring [15], each admissible value of $t$, that is, with $|t| \leq 2p^{1/2}$, is taken, and hence there are about $4p^{1/2}$ isogeny classes. Furthermore, Birch [4] has actually given a formula via the Kronecker class number for the number of isomorphism classes of elliptic curves over a finite field $\mathbb{F}_{q}$ lying in $\mathcal{I}_{t}$. Finally, Lenstra [24] has obtained upper and lower bounds for this number and, in particular, shown that

$$
\#\mathcal{I}_{t} \ll p^{1/2} \log p (\log \log p)^{2}.
$$

Observe that once again bounds for $N(H; \mathcal{B})$ can be translated into bounds for the number of isogenous nonisomorphic curves with coefficients in $\mathcal{B}$, via
multiplication by $p^{1/2+o(1)}$. However, as we have done before, one can obtain better bounds in terms of $T(\mathcal{B})$ given by (47).

Thus, using (49) with $g = 1$ and also (50), we see that for the set $\mathcal{H}(t, \mathcal{B})$ of elliptic curves $H_a \in \mathcal{I}_t$ with $a \in \mathcal{B}$, we have

$$\#\mathcal{H}(t, \mathcal{B}) = \sum_{H \in \mathcal{H}(\mathcal{B}) \cap \mathcal{I}_t} N(H, \mathcal{B})$$

$$\leq (\#\mathcal{I}_t)^{1/2} \left( \sum_{H \in \mathcal{H}(\mathcal{B})} N(H, \mathcal{B})^2 \right)^{1/2} = (\#\mathcal{I}_t)^{1/2} T(\mathcal{B})^{1/2}$$

$$\ll (M^2 p^{-1/4} + p^{1/4} M \log^{1/2} M) (\log p)^{1/2} \log \log p.$$  

This improves the trivial bound

$$\#\mathcal{H}(t, \mathcal{B}) \ll \min\{M^2, p^{3/2} \log p (\log \log p)^2\}$$

(it follows from (50) that there are at most $O(p^{3/2} \log p (\log \log p)^2)$ Weierstrass equations of elliptic curves in the same isogeny class) for $p^{1/4+\varepsilon} \leq M \leq p^{7/8-\varepsilon}$ with any fixed $\varepsilon > 0$. Furthermore, it also implies the lower bound

$$\#\mathcal{I}(\mathcal{B}) \gg \frac{M^2}{\max_{|t| \leq p^{1/2}} \mathcal{H}(t, \mathcal{B})}$$

$$\gg \min\{p^{1/4}, M p^{-1/4} \log^{-1/2} M\} (\log p)^{-1/2} (\log \log p)^{-1}.$$  

ACKNOWLEDGMENTS. The authors are grateful to Alfred Menezes for discussions and useful references on isomorphism classes of hyperelliptic curves. The authors also would like to thank the referee for the careful reading and very useful comments.
