Abstract

Objective: This cross-sectional study examined environmental correlates of sedentary behavior (SB) and physical activity (PA) in preschool children in the urban area of Tianjin, China.

Methods: Data were collected from the Physical Activity and Health in Tianjin Chinese Children study, involving healthy children 3–6 years old and their families. In all children (n = 980), leisure-time SB (LTSB) and leisure-time PA (LTPA) were reported in min/day by parents. In a sub-group (n = 134), overall sedentary time, light PA, and moderate-to-vigorous PA (MVPA) were objectively measured using ActiGraph accelerometry (≥3 days, ≥10 h/day). Environmental correlates were collected using a questionnaire that included home and neighborhood characteristics (e.g., traffic safety, presence of physical activity facilities) and children’s behaviors. Potential correlates were identified using linear regression analysis.

Results: Multiple linear regression analysis showed that “having grandparents as primary caregivers” (βs and 95% confidence intervals (95%CIs) for overall sedentary time: 29.7 (2.1–57.2); LTSB (ln): 0.19 (0.11–0.28)) and “having a television (for LTSB (ln): 0.13 (0.00–0.25)) or computer (for LTSB (ln): 0.13 (0.03–0.23)) in the child’s bedroom” were both associated with higher SB. Furthermore, “having grandparents as primary caregivers” was associated with less MVPA (β (95%CIs): −7.6 (−14.1 to −1.2)), and “active commuting to school by walking” correlated with more MVPA (β (95%CIs): 9.2 (2.2–17.4)). The path model showed that “more neighborhood PA facilities close to home” was indirectly related to higher LTPA (ln), which was partly mediated by “outdoor play” (path coefficients (95%CIs): 0.005 (0.002–0.008)) and “going to these facilities more often” (path coefficients (95%CIs): 0.013 (0.008–0.018)). Traffic safety was not a correlate.

Conclusion: Family structure and media exposure in the home maybe important factors in shaping preschoolers’ PA patterns. Built environmental correlates could indirectly influence preschoolers’ LTPA through parental help with engaging in active behaviors.

Keywords: Active commuting; Built environment; Family structure; Media exposure; Traffic safety

1. Introduction

As the 4th leading cause of death worldwide, physical inactivity is responsible for a substantial economic burden and is becoming a growing problem across the world.1,2 After 4 decades of open reforms since 1979, China has undergone a tremendous transformation in terms of economic development and environmental changes. In this increasingly urbanized country, the daily lives of Chinese citizens have been accompanied by higher community urbanicity, which includes higher vehicle, TV, and computer ownership. All of these have contributed to the rapid decline in physical activity (PA) in China.3 The World Health Organization (WHO) has recommended that children and young people 5–17 years old should accumulate at least 60 min of moderate-to-vigorous PA (MVPA) daily.4 However, the proportion of Chinese children and adolescents who engage in recommended levels of PA has
been declining for decades.\textsuperscript{5,6} Data from the 2017 national survey of 131,859 school students in China showed that only 34.1\% of children and adolescents met the PA guidelines of 1 h of MVPA daily.\textsuperscript{7} Moreover, sedentary behaviors (SBs) of school students increased moderately between 2004 and 2011.\textsuperscript{8}

It is widely accepted that sufficient PA and less sedentary time (ST) have a positive effect on improving both fitness and energy balance in adults,\textsuperscript{9} as well as in school-aged children and adolescents.\textsuperscript{10,11} Over the past 4 decades, the rapid increase in overweight and obesity among school-aged children and adolescents, particularly in urban cities in the mainland of China, is becoming a public health challenge.\textsuperscript{12} For example, a national survey in China in 1985 showed that about 2\% of school students were overweight or obese,\textsuperscript{13} whereas data from the 2017 national survey showed that 15.1\% of 131,859 school students were overweight, and 10.7\% were obese.\textsuperscript{1} This upward trend is also seen in Chinese preschoolers (3–6 years old).\textsuperscript{14}

The preschool years are a critical period of growth and development. It is believed that sufficient PA during the early years of life improves bone and cardiovascular health, assists with the development of mental health, and has a positive influence on cognitive function.\textsuperscript{15} PA promotion in preschool years is considered a key component in early interventions for childhood overweight and obesity.\textsuperscript{16,17} In April 2019, the WHO published recommendations for children under 5 years of age. It was recommended that preschool children (3–4 years old) take part in at least 180 min of activity (with at least 60 min of MVPA) each day, with ST of no more than 1 h per day and less being better.\textsuperscript{18} The 60 min of MVPA (energetic play) for preschoolers was also recommended by Canada (3–4 years old),\textsuperscript{19} Australia (3–5 years old),\textsuperscript{20} and China (3–6 years old),\textsuperscript{21} but was not mentioned in the 2018 Physical Activity Guidelines for American preschoolers (3–5 years old).\textsuperscript{22} However, a recent report showed that only 28\% of Chinese preschool children would meet this guideline based on accelerometer-derived PA.\textsuperscript{22} Thus, to develop evidence-based public health strategies to reduce SB and promote PA from early childhood, there is a need to understand the determinants of the behaviors themselves.

Children’s behaviors are influenced at different levels by a range of individual and social factors, as well as factors relating to the home, community, school environment, and policy.\textsuperscript{23} The 2018 Physical Activity Guidelines for Americans indicated that caregivers have a critical role in supporting and encouraging young children to be physically active and in modeling participation in regular PA.\textsuperscript{24} In Chinese society, the 1-child generation has dramatically changed family structure and lifestyle for almost 35 years (from 1980\textsuperscript{25} to 2015\textsuperscript{26}) on the mainland of China, resulting in the child’s becoming the focus of the entire family.\textsuperscript{27} The literature shows that Chinese adolescents residing with grandparents are less active than those not living with grandparents.\textsuperscript{28} However, less is known about the role played by grandparents in developing and shaping children’s PA patterns during preschool years,\textsuperscript{28} especially in families in which 2 parents work full time, so the grandparents have taken responsibility for the children’s before-school or out-of-school activity (e.g., transportation to school). Home PA facilities or barriers may directly impact children’s behaviors because these facilities or barriers provide caregivers with an opportunity to either encourage children to be active or to inhibit their participation in activities.\textsuperscript{29,30} For example, 1 study found consistent evidence across 12 countries that children (9–11 years old) with at least 1 electronic media device in their bedrooms did less MVPA (4 min/day) than children with no devices.\textsuperscript{31} In another study, children spent more time using electronic media indoors at the expense of engaging in outdoor play.\textsuperscript{31} Furthermore, in present-day China, the neighborhood’s built environment may influence children’s PA behaviors,\textsuperscript{32,33} especially for those with reduced access to public spaces (such as sports areas, parks, and open recreational fields) suitable for leisure-time activities.\textsuperscript{34} A study in the Netherlands indicated that convenient neighborhood PA facilities had an indirect positive effect (through parental support) on PA behaviors of Dutch preschoolers, even in relatively rural areas.\textsuperscript{35} It is important to note that leisure-time PA is considered a dominant form of overall PA among children in developed countries.\textsuperscript{36} Identifying these correlations between built environments and overall and leisure-time PA may help with specific interventions that can promote active lifestyles from an early age. A supportive social environment is also an essential component for enhancing PA in communities, and effective social support is essential for creating active communities.\textsuperscript{37} For example, young children in the United States were found to be more likely to participate in PA in safe neighborhoods.\textsuperscript{38} In contrast, a cross-sectional analysis of a population-based cohort study found that a safe neighborhood was positively associated with higher SB in Swiss preschoolers.\textsuperscript{39} Thus, the influence of the environmental characteristics may vary by country and should be further studied.

The aim of this study was to examine which home and neighborhood environmental characteristics correlated with preschoolers’ sedentary time (STacc) and PA—composed of light physical activity (LPAacc) and moderate-to-vigorous physical activity (MVPAacc)—as measured by ActiGraph accelerometry, as well as their correlation with leisure-time sedentary behaviors (LTSB\(_d\)) and leisure-time physical activity (LTPA\(_d\)) based on a questionnaire reported by parents. It was hypothesized that children living in a supportive environment (e.g., less media exposure in the home or more PA facilities in the neighborhood) would be less sedentary and more active than those living in a nonsupportive environment. Understanding the associations between environmental factors and children’s behaviors in particular settings could be critical for designing specific PA promotion projects. Such evidence would support key strategies for reducing SB and increasing PA among young children in modern urban cities in China.

2. Methods

2.1. The PATH-CC study

Data were derived from the Physical Activity and Health in Tianjin Chinese Children (PATH-CC) study, which focuses on identifying the relationship between environmental determinants,
PA, and overweight among children in Tianjin, China. Details of the study have been reported elsewhere.22 Tianjin is the 4th largest city in northern China, with more than 15 million residents in 2015. Preschools in China generally cater to children 3–6 years old and are under the guidance of the national ministry of education. For example, in Tianjin, most children 3–6 years old attend local preschools in the city.30 Four preschools located in 4 different districts were selected at random for the study. Healthy children were recruited by means of advertising posters in preschools. Children with any disease or disability that could seriously influence daily PA (such as movement difficulties, asthma, or cardiovascular diseases) were excluded from the study. In total, 1031 healthy children and their parents participated in the study between March 2015 and November 2015. The participation rate was 93.7% (i.e., 1031 out of 1100 children in the recruited preschools) (flowchart, Fig. 1). Written informed consent was obtained from the parents, and the study was approved by the Medical Ethics Committee of the Tianjin Medical University and performed in accordance with the Declaration of Helsinki.

2.2. Data collection

The questionnaire data and child anthropometry measurements used in this study were collected in May 2015. Child and family information and environmental characteristics of the home and neighborhood were addressed in the questionnaires, which were sent to parents for data-collection purposes, along with the child leisure-time activities questionnaires. The children’s height and weight were measured by trained school nurses in preschools. Children’s overweight and obesity were classified according to the age-specific and gender-specific cut-offs of Cole and Lobstein.40 From June 2015 to November 2015 (except for summer holidays from July 17 to August 31), daily ST, LPA, and MVPA were assessed in a group of child volunteers participating in the study by using ActiGraph GT3X (Actigraph, Pensacola, FL, USA) accelerometry, and the season (summer or autumn) was recorded for later adjustment.

2.3. Measures of ST, LPA, and MVPA using accelerometry

The ActiGraph has been shown to be a reliable and valid device to measure PA volume and intensity in preschool children. Details of the ActiGraph measurements used in this study have been reported elsewhere.22 Parents were instructed to have their children wear the ActiGraph with an elastic belt on the iliac crest of the right hip for 7 consecutive days during all waking hours, except when bathing or swimming.41 Data were collected using a frequency of 30 Hz. Collected data were analyzed in 15-s epochs. The time spent wearing and not wearing the accelerometer was classified as recommended by Choi et al.,42 and the cut-off points for calculating time spent in ST, LPA, and MVPA were used as recommended by Butte et al.43 To obtain valid measurements in this study, participants had to wear the accelerometer for at least 10 h/day for at least 3 days, regardless of whether these were weekdays or weekend days.44 Time spent doing ST, LPA, and MVPA was calculated as means over at least 3 wearing days.

2.4. Measures of LTSB behaviors and LTPA

Children’s LTSBq and LTPAq were reported by parents or guardians through questionnaires. In this study, leisure time was defined as time spent outside of school hours on weekdays (including interest classes after school and time spent outdoors and at home, but not travel time) and entire weekend days. The LTSBq questionnaire used in this study was adapted from the Neighborhood Impact on Kids Survey—Sedentary Behaviors.45 The LTPAq questionnaire was adapted from a 7-day activity questionnaire for Chinese primary school pupils, and it showed a reliable estimate of the PA during the past week by Chinese children.46 In a pilot study conducted before the survey, 50 parents (37 mothers and 13 fathers) of preschoolers answered questions about their children’s common SB and activities during leisure time. The final version of the LTSBq questionnaire included 5 sedentary behaviors that were found to be most prevalent in preschoolers; 12 activities were included in the LTPAq questionnaire. Parents reported the frequency and duration of these behaviors. For example, the questionnaire asked how many minutes per day, on average, their children spent on each item during leisure time on school days in the past week (response categories ranged 0–5 days) and on days over the past weekend (response categories ranged 0–2 days). The average number of minutes was computed to obtain an overall average LTSBq or LTPAq per day. Details of these behaviors and activities carried out by the children participating in this study are presented in Supplementary Table 1. In the validation study of the leisure-time questionnaire involving 41 children aged 5.3 ± 1.0 years (mean ± SD), children were assessed for 7 continuous days by using both ActiGraph measurements and the questionnaire. A positive
correlation was found between LTSBq and STacc ($\rho = 0.365$, $p = 0.019$), as well as for STacc on weekends or holidays ($\rho = 0.425$, $p = 0.006$) and on school days ($\rho = 0.348$, $p = 0.026$). However, no correlation was found for LTPAq and ActiGraph-derived PA.

2.5. Environmental correlates

Home and neighborhood characteristics were assessed using a revised and translated questionnaire reported on elsewhere. The English questionnaire was translated into Mandarin Chinese by a professional translator and back-translated into English by 2 other translators. The discrepancies were reviewed by an independent translator. All these translators were fluent in both English and Mandarin Chinese. Following the back-translation, the Chinese environmental questionnaire was evaluated in the pilot study together with the leisure-time questionnaires mentioned above. The final version of the environmental questionnaire was adapted according to Chinese cultural background by an expert committee, and it was approved by the original authors. Parents reported their home characteristics (household income; primary caregivers for their child; the presence or absence of an elevator, garden, or car; the number of televisions and computers in the household; and the presence or absence of a television or computer in the child’s bedroom) and children’s PA behaviors (outdoor play and the means of commuting to school). The children’s outdoor play was reported in terms of frequency and duration and given in min per week. Parents reported the walking distance from home to 6 PA facilities (e.g., green area or park) in their neighborhoods and the frequency of taking their children to these facilities each week. A distance index was compiled by combining the 6 places; a higher score meant all places were close to home. The questionnaire also included a scale of social support within families and communities, a scale of traffic safety, and a scale of environmental quality in the neighborhood, assessed by 4 items. An acceptable internal consistency was found for each scale (Cronbach $\alpha$: 0.614–0.712). In this study, the sum score of each item was computed, with higher scores representing better quality. A description of these scales is presented in Supplementary Table 2.

2.6. Statistical analysis

Data were presented as rates in number ($n$) and percentages, as means $\pm$ standard deviations (SDs) or, if data were skewed, as the median within the 25th–75th percentile. Dependent skewed variables (e.g., LTSBq and LTPAq) were transformed as natural logarithms (ln) for linear regression. STacc, LPAacc, and MVPAacc were normally distributed and presented as means by min/day. Differences among groups were tested using a t test: the Mann-Whitney $U$ test or the $\chi^2$ test. To determine the relationships between potential correlates and PA outcomes, linear regression analysis, adjusted for age, gender, and body mass index (BMI), was used. For ActiGraph outcomes, models were also adjusted for season (summer/autumn), because season has been found to be associated with accelerometer-determined PA measurements. Multiple regression models were then used for potential factors (variables with $p < 0.05$ in the univariate analyses) for each outcome. Because “outdoor play” ($\rho = 0.143$, $p < 0.05$) and “frequency of taking children to PA facilities” ($\rho = 0.558$, $p < 0.05$) were both correlated with “distance index”, ordinary least square regression-based path analysis was used to estimate the direct and indirect effects of “distance index” on LTPAq in mediation models with the PROCESS macro for SPSS (Hayes, 2018, http://www.afhayes.com/). In the path model, the “distance index” was entered as an independent variable, “outdoor play” and “frequency of taking children to PA facilities” were entered as mediators, and the other variables were entered as covariates. For the indirect effects, 10,000 bootstrap samples were used for bias-corrected bootstrap confidence intervals. The given path coefficients were shown as unstandardized $\beta$. Missing data were not imputed because only a small proportion (less than 3%) was missing. IBM SPSS Statistics 22 for Windows (IBM Corp., Armonk, NY, USA) was used for this study, with test level $\alpha = 0.05$.

3. Results

The characteristics of the study population are presented in Table 1. A total of 980 children, aged 4.8 $\pm$ 1.1 years, had complete data on parent-reported environmental characteristics, LTSBq, and LTPAq. Of these children, 836 (85%) and their families had lived in their current neighborhood for 1 or more years, and 92 (9%) had lived there for 6 months to 1 year. There were 469 (48%) families who reported living in an apartment that was smaller than 90 m². Thirty-seven mothers and 7 fathers reported having no job during the study. Most children (85%) had a mother with a university degree. The questionnaire data were reported mainly by mothers ($n = 693; 71\%$), with fathers ($n = 210; 21\%$) and grandparents ($n = 77; 8\%$) reporting less often.

With regard to the levels of SB and PA, the questionnaire data on leisure-time activities showed that, on average, children spent more than 2 h per day in SB, LTSBq (132.9 (85.7–188.6)), and more than 1.5 h per day in more active behaviors, LTPAq (104.3 (60.0–168.2)), in min/day. No difference in the level of LTSBq or LTPAq was found between data reported by the mother and data reported by the father (all $p > 0.05$). The subgroup of 134 children aged 5.4 $\pm$ 0.9 years who had valid ActiGraph data (Fig. 1) spent almost 8 h/day being sedentary, STacc (468.6 $\pm$ 80.5 min/day); more than 4 h doing LPA, LPAacc (249.6 $\pm$ 17.1 min/day); and an average of 50 min doing MVPA, MVPAacc (50.5 $\pm$ 17.1 min/day).

The children in the ActiGraph group ($n = 134$) were older than the children in the total questionnaire group ($n = 980, p < 0.05$) because the ActiGraph measurements, which took 6 months, were initiated after the data collection by questionnaire. Most characteristics were comparable between the 2 groups, except for the presence or absence of a lift in the household ($p < 0.05$). Univariate associations between potential correlates and children’s ST and PA outcomes are presented in Supplementary Table 3. No correlation was found between these outcomes and household income; the presence

The results of the sensitivity analysis showed that the findings were materially unchanged, despite lower power (107 children were included). The findings changed for 2 factors: for “season”, which became significant; and for “having grandparents as primary caregivers”; the association attenuated with STacc ($b = 30.6 (-0.2 to 61.4), p = 0.052$), and the
4. Discussion

This study examined the associations of the environmental correlates of SB and PA over the whole day by using ActiGraphs and during leisure time by using questionnaires among preschool children living in a rapidly urbanizing city in the mainland of China. The results showed that the Chinese social culture of children having grandparents as their main caregivers correlated with preschoolers spending more time in SB and less time in MVPA. Children’s outdoor play and active commuting also correlated with more PA (e.g., LTPAq or MVPAacc) and less STacc. Furthermore, parental perception of more PA facilities in the neighborhood may indirectly enhance children’s LTPAq by supporting children in engaging in active behaviors.

Grandparents may play an important role in influencing Chinese preschoolers’ PA patterns, such as a correlation with higher SB and lower MVPA. Grandparent care is a traditional sociocultural custom in Chinese societies.50 Previous researchers have reported that Chinese grandparents had an influence on children’s weight status because of their limited understanding of risk factors for obesity and because they overindulge their grandchildren.51 This may be because many of the older generation experienced a lengthy famine during childhood52 and because the single grandchild is the focus of attention in the Chinese families of today.53 When it comes to PA, they may be overprotective and encourage their grandchildren to engage in less vigorous or even sedentary indoor activities because they are less active themselves and transfer this inclination to a restriction of their grandchildren’s vigorous activities.54 However, a study of preschoolers in Japan found that grandparents had no impact on their grandchildren’s PA.55 One Spanish research study indicated that when parents’ work leads to a difficult and tough situation, the role of grandparents was very important in the life of the family.56 Therefore, family-based education about healthy lifestyle behaviors in young children should involve not only the parents but also the grandparents who care for the children.

Our results showed that access to media equipment, particularly a television or computer in the child’s bedroom, was associated with higher levels of LTSBq in preschoolers. Similar findings have been reported for British children.57 A systematic review found that reducing the parents’ own screen time could lead to a decrease in the children’s screen time.58 A study in Finland examined parental educational levels and preschoolers’ screen time and found that parental role models, attitudes, and norms were important mediators of preschoolers’ screen time.59 Thus, to reduce SB in the household, support and behavioral interventions by parents are needed. Family-based strategies to limit media access may be an important way to reduce children’s SB during leisure time. For example, “removing electronic media from children’s bedrooms” was seen as useful in targeted obesity-prevention initiatives.60 This strategy could also be used to minimize ST in the early years.61 Furthermore, recommendations about the use of mobile media for young children are needed.62 Our study showed that 62% of children interact with a mobile phone, tablet, or electronic games for 30 min per day 5 days per week (Supplementary Table 1).

Our study also confirmed a correlation between families’ having and using PA facilities in their neighborhood and young children’s LTPAq. This finding was consistent with that of a previous study, which demonstrated that access to PA destinations correlates with LTPA in Chinese adults.63 Another study, in Hong Kong, China, reported that building more neighborhood sports facilities may help active adolescents to maintain or increase their LTPA.64 For preschool children, as expected, the influence of the built environment was indirect and required the parents’ or caregivers’ support because young children are less autonomous than adults.35 More and more evidence shows that parents’ PA has a positive influence on children’s PA.65,66 For example, a study in Canada found that maternal support was significantly related to preschoolers’...
Correlates of physical activity in preschoolers

objectively measured ST, LPA, and MVPA. Thus, improving the availability of PA facilities is a sensible action to take, not least because children and their caregivers can then do activities together, which benefits both groups.

In addition, some environmental correlates may influence other PA domains, and this needs to be studied further. Although no evidence was found in our study that parental perception of “traffic safety” was a correlate of children’s PA behaviors, parental perception of greater “traffic safety” was associated with children’s active commuting to school ($p = 0.102, p < 0.05$), and more “social support” was associated with children spending more time in “outdoor play” ($p = 0.223, p < 0.05$). In addition, more “social support” ($p = 0.272, p < 0.05$) and “higher quality of neighborhood environments” were both associated with children going to PA facilities more frequently ($p = 0.165, p < 0.05$). Therefore, comprehensive correlation of supportive school environments, active transportation, safe neighborhoods, and supportive home environments should be studied further; multiple approaches to public health policy should be made to promote sufficient PA.

To the best of our knowledge, this is the first study that examined correlates of home and neighborhood characteristics in the PA patterns of Chinese preschool children. An important strength of this study was that it investigated both correlates of objectively measured PA throughout the day and subjectively measured PA and SB during leisure time. This provided a better understanding of how different environmental factors influence children’s behaviors in particular settings. Limitations of the present study include its cross-sectional design, which means that causality cannot be addressed. Also, environmental characteristics, LTPA$_q$ and LTSB$_q$ were reported by parents, so findings must be interpreted with caution. Furthermore, it is not known how these results would translate to other populations in a different part of the world because the children in this study were recruited in a single Chinese city, and the correlates for being sedentary or active are likely to depend on the area-specific context.

5. Conclusion

This study provides evidence showing that children’s caregivers, children’s active behaviors, media exposure at home, and better neighborhood facilities are important factors in shaping Chinese preschoolers’ PA patterns. The promotion of PA for young children should take into consideration the children’s caregivers and their influence on children’s active behaviors. Having convenient neighborhood PA facilities may not be enough to enhance children’s PA throughout the day. Thus, a comprehensive approach, including supportive home environments, active transportation, and safe and supportive school and neighborhood environments, is needed to prevent deterioration in young children’s PA patterns.

Acknowledgments

The authors are grateful to the families who took part in the PATH-CC study, to the teachers and school nurses for their help in recruiting and conducting measurements of participants, and to the entire team of the PATH-CC study. This study was supported by Tianjin Medical University and the University Medical Center Groningen. No sponsor was involved in the study design, data collection or analysis, interpretation of the data, writing of the manuscript, or decision to submit the paper for publication.

Authors’ contributions

EC and CL designed the study; EC, CL, TS and GH were involved in the data analysis and interpretation, and CL drafted the manuscript. All authors were involved in the revision of the manuscript and approved the final version of the submitted manuscript. All authors have read and approved the final manuscript and agree with the order of the presentation of authors.

Competing interests

The authors declare that they have no competing interests.
