Abstract

We present data testing the existence of a parity-flavor breaking phase in simulations of QCD with two flavors of light Wilson fermions. This is done by explicit simulations on lattice sizes of $6^4$, $8^4$ and $10^4$ for a variety of values of $\beta$ and $\kappa$ as well as the coefficient, $h$, of an explicit breaking term included in the action. We find that at $\beta = 6/g^2$ equal to or greater than 5.0 extrapolation in the parameter $h$ as well as in the lattice volume show no indication of a phase where parity and flavor are spontaneously broken in the limit of zero $h$.

*Submitted to Physical Review D.
\section{Introduction}

For many years now, Aoki \cite{1, 2, 3, 4, 5} and collaborators \cite{6, 7, 8} have been advocating the existence of a parity-flavor breaking phase in QCD with Wilson fermions as a means of explaining why the pion mass in this model approaches small values as the Wilson parameter $\kappa$ approaches, for every value of inverse square coupling $\beta$, a critical value $\kappa_c$. This in spite of no-go theorems \cite{9, 10} that forbid such a phase in the continuum limit.

Indeed analytic arguments have been presented to support the existence of such a phase at $\beta = 0.0$. For finite and, in particular, larger values of $\beta$ where current lattice simulations are undertaken, such evidence is lacking \cite{8}.

Although the picture advocated by Aoki may explain the smallness of the pion masses as $\kappa$ approaches $\kappa_c$ it also explicitly states that these pions are not the Goldstone modes of spontaneous chiral symmetry breaking. This presents a problem in that it is not then clear that any of the soft pion and other theorems associated with this phenomenon will be respected on the lattice. In other words this would not be the expected simulation of true QCD. In fact the large $N$ analytic analysis which indicates the existence of this phase at $\beta = 0.0$ also shows the non-vanishing of the $\pi - \pi$ scattering length which is contrary to the the expected spontaneous chiral symmetry breaking of QCD. This is of course unimportant at $\beta = 0.0$ but is very important, if true, at the values of $\beta$ where current simulations are performed.

The alternative picture where the explicit chiral symmetry breaking Wilson term causes the (otherwise Goldstone) pions to acquire a small mass proportional to the lattice spacing does not have such a problem. Indeed, that all these extra effects would disappear as the lattice spacing is made smaller with the approach to the continuum limit was formally demonstrated some time ago \cite{11, 12, 13}.

Several models exhibit a parity-flavor breaking phase. In the Nambu-Johna-Lassinio \cite{14, 15} model with Wilson fermions this phase was numerically and, in the large $N$ approximation, analytically \cite{14, 16} confirmed for values of $\beta$ up to a specific cutoff value. This phase disappears for larger values of $\beta$. The Schwinger model with two flavors of Wilson fermions exhibits this phase at strong coupling and also loses it at weak coupling \cite{17}. Whereas the picture advocated by Aoki does not anticipate such a quenching effect for the phase in QCD, recent phenomenological arguments by Creutz \cite{18} tend to show a preference for quenching of this phase if it exists.

Thus it becomes necessary to explore this important feature by explicit simulations of QCD with Wilson fermions on volumes larger than those already studied \cite{8}.

\section{Signature of the Broken Phase}

Following arguments presented by Aoki and Aoki and Gocksch \cite{1, 8}, it is necessary, in order to investigate the presence of the parity-flavor-breaking phase in simulations, to introduce first an explicit breaking term into the action and then extrapolate the measured order parameter as this term tends to zero. Since the extrapolation is to be done, in principle, after the ‘infinite volume’ limit is taken, such simulations must be done for larger volumes and any order parameter extrapolation be studied as a function of this increasing volume.
Figure 1: Expected variation of computed order parameter with volume.

In such a situation a typical behaviour of the data at finite volumes that one might expect is shown in Fig. 1. It is expected that the functional dependence of the (measured) order parameter on $h$ be such that for any finite volume this order parameter vanishes at $h = 0$. The variation of this dependence with increasing volume is crucial to the initial determination of the existence of a broken phase or its absence. The existence of a broken phase in the infinite volume limit is signaled by a flattening of this dependence for larger values of $h$ and a sharper drop to zero as $h$ approaches zero. Thus it is clear that a significant volume dependence of the order parameter at smaller values of $h$ is a necessary indicative factor for this phase. If, on the other hand, the approach to zero is not varying significantly as the volume increases, the infinite volume limit will not sustain a broken phase.\footnote{If one is not careful one may arrive at wrong conclusions. If simulations are done only at larger values of $h$ one may use the slightly varying values of the order parameter there to extrapolate these to infinite volume. If this step is then followed by a linear extrapolation to $h = 0.0$ a non-zero value for the order parameter at $h = 0.0$ may be obtained. At this stage it is tempting to conclude that a broken phase exists in that limit. This may be the wrong conclusion if this is not accompanied by a significant increase in the value of the order parameter at smaller values of $h$.}

3 Numerical Simulations

We report here on simulations done with two flavors of Wilson fermions at $\beta = 5.0, 5.5,$ and $8.0$ on volumes of $6^4, 8^4,$ and $10^4$ for a variety of values of $\kappa$ ranging from less than the appropriate $\kappa_c$ to values greater than $\kappa_c$.

The choice of these three values of $\beta$ was determined as follows. The value $\beta = 5.5$ represents current simulations on larger lattices where spectrum and matrix element calculations
are being done; that at $\beta = 5.0$ represents a lower value below which relevance to continuum physics is not expected, and the last value at $\beta = 8.0$ is to extend the search to a much larger value of $\beta$ in case the parity-flavor breaking phase were to be confirmed at the two smaller values.

We introduce into the QCD action a term of the form $ih\bar{\psi}\gamma_5\tau_3\psi$ where $\tau_3$ is a $2 \times 2$ matrix representing the third element of the generators of flavor SU(2) algebra. Upon integrating the fermionic variables this is reflected in the simulation by the product of two determinants: $DetM(h) * DetM(-h)$ where $M(h)$ is given by a simple modification of the Wilson Matrix $M_w$ as:

$$M(h) = M_w + ih\gamma_5$$

As pointed out by Aoki, we also have here

$$\gamma_5 M(-h)\gamma_5 = M^\dagger$$

and:

$$DetM(-h) = DetM^\dagger(h).$$

Simulations were done for the parameter $h$ taking values ranging from 0.001 to 0.3. For the volume dependence we concentrate on the smaller values of $h$ and in particular $h = 0.001$ and $h = 0.005$ for all three volumes considered and mostly for values of $\kappa$ greater than $\kappa_c$.

The order parameter we compute is the expectation value of the operator $i\bar{\psi}\gamma_5\tau_3\psi$. With our notation this is given as

$$PF = Im Tr(\gamma_5 M^{-1}(h))$$

4 Results

For the three values of $\beta$ considered, simulations were performed, as mentioned above, at various values of $\kappa$ both below and above $\kappa_c$. We shall present the data and results for each value of $\beta$ considered separately.

In all cases these simulations were also done at various values of the external parameter $h$. For each $\kappa$ the results of the computations on the three volumes $L^4$, $L = 6, 8, 10$ were compared at the two values of $h = 0.001$, and $h = 0.005$. The variation of the order parameter with $1/L$ is then used to obtain an ‘infinite volume’ limit for all values of $h$ used. The choice of $1/L$ is indicated here by the naive dimension of the order parameter. Following this, the order parameter at these values of $h$ were fitted to:

$$PF = A + Bh^{\frac{1}{2}} + Ch + Dh^2$$

A separate fit to the pure quadratic polynomial

$$PF = A + Ch + Dh^2$$

was also done.
Table 1: Parameters and measured order parameter $PF_L$ for the case of $\beta = 5.0$ on lattices of volume $L^4$, for $L = 6, 8, \text{ and } 10$.

The initial aim in this case is to detect the possible existence of any non-zero constant $A$ at $h = 0.0$ as the limit of the order parameter at that point. This is of particular interest for comparing results at values of $\kappa$ above $\kappa_c$ with those below $\kappa_c$.

It is useful to point out here that in the presence of a parity-flavor breaking phase the order parameter is expected to vary with $h$ as:

$$PF_\infty = A + Bh^\frac{1}{3} + \ldots,$$

this being the behaviour of the root of the cubic equation determining the position of the minimum of the quartic effective potential. In the absence of such a phase the same behaviour follows with $A = 0.0$. As the quartic potential becomes quadratic the leading behaviour becomes:

$$PF = Ch + \ldots$$

This should, when compared to the data, be also a useful tool in determining which situation one is in.

4.1 $\beta = 5.0$

The value of $\kappa_c$ at this value of $\beta$ is known to be about 0.18. We consequently performed simulations well below that value at $\kappa = 0.15$ and well above it at $\kappa = 0.1875$ and intermediate values in between. We present in table the results of these simulations.
Figure 2: (a) Histogram of computed PF at $\beta = 5.0 \, \kappa = 0.15 \, h = 0.001$ for all volumes considered; and (b) Histogram of computed PF at $\beta = 5.0 \, \kappa = 0.185 \, h = 0.005$ for all volumes considered.

The results in table 1 clearly show also that the values computed for the order parameter at the larger values of the volume are only incrementally different from those measured on the small volume for all values of $\kappa$ indicated. For values of $\kappa$ less than $\kappa_c$, these results are consistent within errors. This is best illustrated by the overlapping histograms of these measurements at $\kappa = 0.15$ given in Fig. 2a. For $\kappa = 0.185$ a similar histogram, Fig. 2b, indicates only an incremental increase of the peak of the distribution with volume. This incremental change may be used to obtain an ‘infinite volume limit’ of these values assuming a linear extrapolation in $\frac{1}{L^4}$ where $L$ is the lattice linear dimension as shown for example in Figs. 3a, b, c, and d. It is clear here that the data is consistent with being essentially ‘constant’ with volume. A quadratic fit in $h$ to this ‘infinite volume values’ is not significantly different from a fit to the data at volume $6^4$ where we obtain – for example, Figs. 4a and b – a zero constant for the extrapolated value of the order parameter at $h = 0.0$ for $\kappa = 0.15$ below $\kappa_c$ and $\kappa = 0.182$ slightly above it. For values of $\kappa$ both below and above $\kappa_c$ this clearly implies the absence of any volume dependence of the order parameter and, hence, in both cases and in particular the latter case, the absence of a flavor-parity breaking phase in the system at $\beta = 5.0$. A fit with a leading $h^4$ is not as a good a description of the data as it leads to a much higher $\chi^2$–square. Hence, we further conclude that the effective potential of the system is predominantly quadratic at small $h$.

4.2 $\beta = 5.5$

The value of $\kappa_c$ in this case is also known to be in the neighborhood of $\kappa = 0.16$. Table 2 details the results of our computations for values of $\kappa$ well below and above this value. We concentrate in this discussion on the results obtained at $\kappa = 0.162$ and 0.165 both above $\kappa_c$ and where the postulated phase is expected to exist.
We show in Fig. 5 the variation of the computed order parameter with $\kappa$ over the range used for $h = 0.001$. No sharp change is indicated as the value of $\kappa_c = 0.16$ is crossed.

Analysis similar to that described above is also performed for this data set. The results at the larger volumes show only an incremental increase, if any, as shown, for example, for the case of $\kappa = 0.162$ at both $h = 0.001$ and $h = 0.005$, in Figs. 6a and b.

Here again an ‘infinite volume’ limit may indeed be inferred and a quadratic fit in $h$ gives for the ‘constant’ in the fit a value which is consistent with zero as shown in Figs. 7a, and b for $\kappa = 0.162$ and $\kappa = 0.165$.

We are then again led to conclude the absence of a parity-flavor breaking phase at these values of $\kappa$ above $\kappa_c$.

 Attempts at fits with a leading $h^{1/2}$ behaviour again lead invariably to worse fits indicating again a dominant quadratic behaviour of the effective potential for the order parameter.
4.3 $\beta = 8.0$

The value of $\kappa_c$ in this case has not been determined numerically. We estimate its value using a tadpole improved perturbative procedure as discussed in [19]. We obtain in this case a value in the neighborhood of $\kappa_c \simeq 0.145$. Consequently our simulations are performed at values of $\kappa$ below and above this value as shown in Table 3.

We show in Fig. 8 the variation of the computed order parameter with $\kappa$ over the range used. No sharp change is indicated as the value of $\kappa_c \simeq 0.145$ is crossed.

| 0.1650   | 0.050| 1.047(23)  | 1.056(14)  |             |
| 0.1650   | 0.100| 1.966(35)| 1.984(21)  |             |
| 0.1650   | 0.300| 4.354(50)|            |             |

We concentrate here on the data at the values of $\kappa$ above $\kappa_c$. Using the same procedure as above essentially the same conclusion follows. Figs. 9a and b show that no significant change in the evaluation of the order parameter at the larger volumes exists for $\kappa = 0.146$ at $h = 0.005$ and as seen by the overlapping histograms for $\kappa = 0.15$ at $h = 0.005$.

Furthermore, quadratic fits in $h$ at, for example, $\kappa = 0.146$ and $\kappa = 0.16$ again have a leading ‘constant’ that is consistent with zero as shown in Figs. 10a and b, respectively. Therefore, one is led again to the absence of any signal for a parity-flavor breaking phase at this value of $\beta$.

Finally the obvious leading linear dependence of the fit indicates again a dominant quadratic effective potential at this value of $\beta$ as well.

5 Conclusions

It is clear from the discussion above that QCD with two flavors of Wilson fermions does not exhibit a parity-flavor breaking phase at $\beta > 5.0$ as postulated by Aoki and collaborators.
Figure 6: (a) PF vs. $\frac{1}{L}$ for $\beta = 5.5$, $\kappa = 0.162$, $h = 0.001$; and (b) PF vs. $\frac{1}{L}$ for $\beta = 5.5$, $\kappa = 0.162$, $h = 0.005$.

Since it has been demonstrated that at $\beta = 0.0$ such a phase may exist in a large $N$ (color) limit, it is also clear that if this phase does extend beyond $\beta = 0.0$, it must pinch out in a manner similar to that in the NJL model at $\beta < 5.0$. In either case this phase would not be relevant for the discussion of the approach to the chiral limit in QCD and the ensuing Goldstone nature of the pions for $\beta > 5.0$. In fact, all indications are such that, as shown formally sometime ago, this is simply related to the approach to zero lattice spacing and infinite volume.

Figure 7: (a) PF vs. $h$ for $\beta = 5.5$, $\kappa = 0.162$ and a quadratic fit; and (b) PF vs. $h$ for $\beta = 5.5$, $\kappa = 0.165$ and a quadratic fit.

Acknowledgements

I wish to thank Urs Heller for providing a modified QCD code for performing the simulations reported in this paper. All these simulations were done on the SCRI IBM compute cluster. This research was supported by the U.S. Department of Energy through Contract Nos. DE-FG05-92ER40742 and DE-FC05-85ER250000.
Figure 8: Variation of PF with $\kappa$ at $\beta = 8.0$ and $h = 0.005$.

Figure 9: (a) PF vs. $\frac{1}{L}$ for $\beta = 8.0 \kappa = 0.146 \ h = 0.005$; and (b) Histogram of computed PF at $\beta = 8.0 \kappa = 0.15 \ h = 0.005$ for all volumes considered.
