BOREL CONJECTURE AND DUAL BOREL CONJECTURE

MARTIN GOLDSTERN, JAKOB KELLNER, SAHARON SHELAH, AND WOLFGANG WOHOFSKY

Dedicated to the memory of Richard Laver (1942–2012)

Abstract. We show that it is consistent that the Borel Conjecture and the dual Borel Conjecture hold simultaneously.

INTRODUCTION

History. A set $X$ of reals\footnote{In this paper, we use $2^\omega$ as the set of reals ($\omega = \{0, 1, 2, \ldots\}$). By well-known results both the definition and the theorem also work for the unit interval $[0, 1]$ or the torus $\mathbb{R}/\mathbb{Z}$. Occasionally we also write “$x$ is a real” for “$x \in \omega^\omega$”.
} is called “strong measure zero” (smz) if for all functions $f : \omega \to \omega$ there are intervals $I_n$ of measure $\leq 1/f(n)$ covering $X$. Obviously, an smz set is a null set (i.e., has Lebesgue measure zero), and it is easy to see that the family of smz sets forms a $\sigma$-ideal and that perfect sets (and therefore uncountable Borel or analytic sets) are not smz.

At the beginning of the 20th century, Borel [Bor19, p. 123] conjectured:

Every smz set is countable.

This statement is known as the “Borel Conjecture” (BC). In the 1970s it was proved that BC is independent, i.e., neither provable nor refutable.

Let us very briefly comment on the notion of independence: A sentence $\varphi$ is called independent of a set $T$ of axioms if neither $\varphi$ nor $\neg \varphi$ follows from $T$. (As a trivial example, $(\forall x)(\forall y)x \cdot y = y \cdot x$ is independent from the group axioms.) The set theoretic (first order) axiom system ZFC (Zermelo Fraenkel with the axiom of choice) is considered to be the standard axiomatization of all of mathematics: A mathematical proof is generally accepted as valid iff it can be formalized in ZFC. Therefore we just say “$\varphi$ is independent” if $\varphi$ is independent of ZFC. Several mathematical statements are independent; the earliest and most prominent example is Hilbert’s first problem, the Continuum Hypothesis (CH).

BC is independent as well: Sierpiński [Sie28] showed that CH implies $\neg$BC (and, since Gödel showed the consistency of CH, this gives us the consistency of $\neg$BC). Using the method of forcing, Laver [Lav76] showed that BC is consistent.
Galvin, Mycielski and Solovay [GMS73] proved the following conjecture of Prikry:

\[ X \subseteq 2^\omega \text{ is smz if and only if every comeager (dense } G_\delta \text{) set contains a translate of } X. \]

Prikry also defined the following dual notion:

\[ X \subseteq 2^\omega \text{ is called “strongly meager” (sm) if every set of Lebesgue measure } 1 \text{ contains a translate of } X. \]

The dual Borel Conjecture (dBC) states:

Every sm set is countable.

Prikry noted that CH implies \( \neg \text{dBC} \) and conjectured dBC to be consistent (and therefore independent), which was later proved by Carlson [Car93].

Numerous additional results regarding BC and dBC have been proved: The consistency of variants of BC or of dBC, the consistency of BC or dBC together with certain assumptions on cardinal characteristics, etc. See [BJ95, Ch. 8] for several of these results. In this paper, we prove the consistency (and therefore independence) of BC+dBC (i.e., consistently BC and dBC hold simultaneously).

**The problem.** The obvious first attempt to force BC+dBC is to somehow combine Laver’s and Carlson’s constructions. However, there are strong obstacles:

Laver’s construction is a countable support iteration of Laver forcing. The crucial points are:

- Adding a Laver real makes every old uncountable set \( X \) non-smz
- and this set \( X \) remains non-smz after another forcing \( P \), provided that \( P \) has the “Laver property”.

So we can start with CH and use a countable support iteration of Laver forcing of length \( \omega_2 \). In the final model, every set \( X \) of reals of size \( \aleph_1 \) already appeared at some stage \( \alpha < \omega_2 \) of the iteration; the next Laver real makes \( X \) non-smz, and the rest of the iteration (as it is a countable support iteration of proper forcings with the Laver property) has the Laver property, and therefore \( X \) is still non-smz in the final model.

Carlson’s construction on the other hand adds \( \omega_2 \) many Cohen reals in a finite support iteration (or equivalently finite support product). The crucial points are:

- A Cohen real makes every old uncountable set \( X \) non-sm
- and this set \( X \) remains non-sm after another forcing \( P \), provided that \( P \) has precaliber \( \aleph_1 \).

So we can start with CH and use more or less the same argument as above: Assume that \( X \) appears at \( \alpha < \omega_2 \). Then the next Cohen makes \( X \) non-sm. It is enough to show that \( X \) remains non-sm at all subsequent stages \( \beta < \omega_2 \). This is guaranteed by the fact that a finite support iteration of Cohen reals of length \( < \omega_2 \) has precaliber \( \aleph_1 \).

So it is unclear how to combine the two proofs: A Cohen real makes all old sets smz, and it is easy to see that whenever we add Cohen reals cofinally often in an iteration of length \( \omega_2 \), all sets of any intermediate extension will be smz, thus violating BC. So we have to avoid Cohen reals\(^2\), which also implies that we cannot

---

\(^2\)An iteration that forces dBC without adding Cohen reals was given in [BS10] using non-Cohen oracle-cc.
use finite support limits in our iterations. So we have a problem even if we find a
replacement for Cohen forcing in Carlson’s proof that makes all old uncountable
sets \( X \) non-sm and that does not add Cohen reals: Since we cannot use finite
support, it seems hopeless to get precaliber \( \aleph_1 \), an essential requirement to keeping
\( X \) non-sm.

Note that it is the proofs of BC and dBC that are seemingly irreconcilable; this is not clear for the models. Of course Carlson’s model, i.e., the Cohen model,
cannot satisfy BC, but it is not clear whether maybe the Laver model could already
satisfy dBC. (It is even still open whether a single Laver forcing makes every old
uncountable set non-sm.) Actually, Bartoszyński and Shelah [BS03] proved that
the Laver model does satisfy the following weaker variant of dBC (note that the
continuum has size \( \aleph_2 \) in the Laver model):

Every sm set has size less than the continuum.

In any case, it turns out that one can reconcile Laver’s and Carlson’s proof by
“mixing” them “generically”, resulting in the following theorem:

**Theorem.** If ZFC is consistent, then ZFC+BC+dBC is consistent.

**Prerequisites.** To understand anything of this paper, the reader

- should have some experience with finite and countable support iteration,
  proper forcing, \( \aleph_2 \)-cc, \( \sigma \)-closed, etc.,
- should know what a quotient forcing is,
- should have seen some preservation theorem for proper countable support
  iteration,
- should have seen some tree forcings (such as Laver forcing).

To understand everything, additionally the following is required:

- The “case A” preservation theorem from [She98]; more specifically we build
  on the proof of [Go93] (or [GK06]).
- In particular, some familiarity with the property “preservation of randoms”
  is recommended. We will use the fact that random and Laver forcing have
  this property.
- We make some claims about (a rather special case of) ord-transitive models
  in Section 3.A. The readers can either believe these claims, check them
  themselves (by some rather straightforward proofs), or look up the proofs
  (of more general settings) in [She04] or [Ke12].

From the theory of strong measure zero and strongly meager, we only need the
following two results (which are essential for our proofs of BC and dBC, respectively):

- Pawlikowski’s result from [Paw96a] (which we quote as Theorem 0.2 below) and
- Theorem 8 of Bartoszyński and Shelah’s [BS10] (which we quote as Lemma
  2.1).

We do not need any other results of Bartoszyński and Shelah’s paper [BS10]; in
particular, we do not use the notion of non-Cohen oracle-cc (introduced in [She06]).
Also, the reader does not have to know the original proofs of Con(BC) and Con(dBC)
by Laver and Carlson, respectively.
The third author claims that our construction is more or less the same as a non-Cohen oracle-cc construction and that the extended version presented in [She10] is even closer to our preparatory forcing.

Notation and some basic facts on forcing, strongly meager (sm) and strong measure zero (smz) sets. We call a lemma “Fact” if we think that no proof is necessary — either because it is trivial, because it is well known (even without a reference), or because we give an explicit reference to the literature.

Stronger conditions in forcing notions are smaller, i.e., $q \leq p$ means that $q$ is stronger than $p$.

Let $P \subseteq Q$ be forcing notions. (As usual, we abuse notation by not distinguishing between the underlying set and the quasiorder on it.)

- For $p_1, p_2 \in P$ we write $p_1 \perp_P p_2$ for “$p_1$ and $p_2$ are incompatible”. Otherwise we write $p_1 \parallel_P p_2$. (We may just write $\perp$ or $\parallel$ if $P$ is understood.)
- $q \leq^* p$ (or $q \leq^* p$) means that $q$ forces that $p$ is in the generic filter or equivalently that every $q' \leq q$ is compatible with $p$. Also, $q =^* p$ means $q \leq^* p \land p \leq^* q$.
- $P$ is separative if $\leq$ is the same as $\leq^*$ or, equivalently, if for all $q, p$ with $q \nleq p$ there is an $r \leq p$ incompatible with $q$. Given any $P$, we can define its “separative quotient” $Q$ by first replacing (in $P$) $\leq$ by $\leq^*$ and then identifying elements $p, q$ whenever $p =^* q$. Then $Q$ is separative and forcing equivalent to $P$.
- “$P$ is a subforcing of $Q$” means that the relation $\leq_P$ is the restriction of $\leq_Q$ to $P$.
- “$P$ is an incompatibility-preserving subforcing of $Q$” means that $P$ is a subforcing of $Q$ and that $p_1 \perp_P p_2$ iff $p_1 \perp_Q p_2$ for all $p_1, p_2 \in P$.

Additionally, let $M$ be a countable transitive model (of a sufficiently large subset of ZFC) containing $P$.

- “$P$ is an $M$-complete subforcing of $Q$” (or $P \prec_M Q$) means that $P$ is a subforcing of $Q$, and if $A \subseteq P$ is in $M$ a maximal antichain, then it is a maximal antichain of $Q$ as well. (Or equivalently, $P$ is an incompatibility-preserving subforcing of $Q$ and every predense subset of $P$ in $M$ is predense in $Q$.) Note that this means that every $Q$-generic filter $G$ over $V$ induces a $P$-generic filter over $M$, namely $G^M := G \cap P$ (i.e., every maximal antichain of $P$ in $M$ meets $G \cap P$ in exactly one point). In particular, we can interpret a $P$-name $\tau$ in $M$ as a $Q$-name. More exactly, there is a $Q$-name $\tau'$ such that $\tau[G] = \tau[G^M]$ for all $Q$-generic filters $G$. We will usually just identify $\tau$ and $\tau'$.
- Analogously, if $P \in M$ and $i : P \to Q$ is a function, then $i$ is called an $M$-complete embedding if it preserves $\leq$ (or at least $\leq^*$) and $\perp$. Moreover, if $A \in M$ is predense in $P$, then $i[A]$ is predense in $Q$.

There are several possible characterizations of sm (“strongly meager”) and smz (“strong measure zero”) sets; we will use the following as definitions:

A set $X$ is not sm if there is a measure 1 set into which $X$ cannot be translated; i.e., if there is a null set $Z$ such that $(X + t) \cap Z \neq \emptyset$ for all reals $t$ or, in other

\(^3\)We will also use so-called ord-transitive models, as defined in Section 3.A.
words, $Z + X = 2^\omega$. To summarize:

$$(0.1) \quad X \text{ is not sm iff there is a Lebesgue null set } Z \text{ such that } Z + X = 2^\omega.$$  

We will call such a $Z$ a “witness” for the fact that $X$ is not sm (or say that $Z$ witnesses that $X$ is not sm).

The following theorem of Pawlikowski\cite{Paw96a} is central for our proof\footnote{We thank Tomek Bartoszyński for pointing out Pawlikowski’s result to us and for suggesting that it might be useful for our proof.} that BC holds in our model:

**Theorem 0.2.** $X \subseteq 2^\omega$ is smz iff $X + F$ is null for every closed null set $F$. Moreover, for every dense $G_\delta$ set $H$ we can construct (in an absolute way) a closed null set $F$ such that for every $X \subseteq 2^\omega$ with $X + F$ null there is $t \in 2^\omega$ with $t + X \subseteq H$.

In particular, we get:

$$(0.3) \quad X \text{ is not smz iff there is a closed null set } F \text{ such that } X + F \text{ has positive outer Lebesgue measure.}$$

Again, we will say that the closed null set $F$ “witnesses” that $X$ is not smz (or call $F$ a witness for this fact).

**Annotated contents.**

Section 1: We introduce the family of ultralaver forcing notions and prove some properties.

Section 2: We introduce the family of Janus forcing notions and prove some properties.

Section 3: We define ord-transitive models and mention some basic properties. We define the “almost finite” and “almost countable” support iteration over a model. We show that in many respects they behave like finite and countable support, respectively.

Section 4: We introduce the preparatory forcing notion $\mathbb{R}$ which adds a generic forcing iteration $\bar{\mathbb{P}}$.

Section 5: Putting everything together, we show that $\mathbb{R} \ast \mathbb{P}_{\omega_2}$ forces BC+dBC, i.e., that an uncountable $X$ is neither smz nor sm. We show this under the assumption $X \in V$ and then introduce a factorization of $\mathbb{R} \ast \mathbb{P}$ to show that this assumption does not result in loss of generality.

Section 6: We briefly comment on alternative ways some notions could be defined.

An informal overview of the proof, including two illustrations, can be found at [http://arxiv.org/abs/1112.4424/](http://arxiv.org/abs/1112.4424/).

1. **Ultralaver forcing**

In this section, we define the family of ultralaver forcings $\mathbb{L}_D$, variants of Laver forcing which depend on a system $D$ of ultrafilters.

In the rest of the paper, we will use the following properties of $\mathbb{L}_D$. (We will use only these properties, so readers who are willing to take these properties for granted could skip to Section 2.)

1. $\mathbb{L}_D$ is $\sigma$-centered, hence ccc.

   (This is Lemma 1.2)

2. $\mathbb{L}_D$ is separative.

   (This is Lemma 1.3)
(3) **Ultrapower kills smz:** There is a canonical \( \mathbb{L}_D \)-name \( \overline{\ell} \) for a fast growing real in \( \omega^\omega \) called the ultralaver real. From this real, we can define (in an absolute way) a closed null set \( F \) such that \( X + F \) is positive for all uncountable \( X \) in \( V \) (and therefore \( F \) witnesses that \( X \) is not smz, according to Theorem [0.2]).

(This is Corollary [1.21])

(4) Whenever \( X \) is uncountable, then \( \mathbb{L}_D \) forces that \( X \) is not “thin”.

(This is Corollary [1.24])

(5) If \( (M, \in) \) is a countable model of ZFC* and if \( \mathbb{L}_{DM} \) is an ultralaver forcing in \( M \), then for any ultrafilter system \( D \) extending \( D^M \), \( \mathbb{L}_{DM} \) is an \( M \)-complete subforcing of the ultralaver forcing \( \mathbb{L}_D \).

(This is Lemma [1.3])

Moreover, the real \( \overline{\ell} \) of item (3) is so “canonical” that we get: If (in \( M \)) \( \overline{\ell}^M \) is the \( \mathbb{L}_{DM} \)-name for the \( \mathbb{L}_{DM} \)-generic real, and if (in \( V \)) \( \overline{\ell} \) is the \( \mathbb{L}_D \)-name for the \( \mathbb{L}_D \)-generic real, and if \( H \) is \( \mathbb{L}_D \)-generic over \( V \) and thus \( H^M := H \cap \mathbb{L}_{DM} \) is the induced \( \mathbb{L}_{DM} \)-generic filter over \( M \), then \( \overline{\ell}[H] \) is equal to \( \overline{\ell}^M[H^M] \).

Since the closed null set \( F \) is constructed from \( \overline{\ell} \) in an absolute way, the same holds for \( F \), i.e., the Borel codes \( F[H] \) and \( F[H^M] \) are the same.

(6) Moreover, given \( M \) and \( \mathbb{L}_{DM} \) as above and a random real \( r \) over \( M \), we can choose \( D \) extending \( D^M \) such that \( \mathbb{L}_D \) forces that randomness of \( r \) is preserved (in a strong way that can be preserved in a countable support iteration).

(This is Lemma [1.30])

1. A. **Definition of ultralaver forcing.**

**Notation.** We use the following fairly standard notation:

A **tree** is a non-empty set \( p \subseteq \omega^{< \omega} \) which is closed under initial segments and has no maximal elements. The elements (“nodes”) of a tree are partially ordered by \( \subseteq \).

For each sequence \( s \in \omega^{< \omega} \) we write \( \text{lth}(s) \) for the length of \( s \).

For any tree \( p \subseteq \omega^{< \omega} \) and any \( s \in p \) we write \( \text{succ}_p(s) \) for one of the following two sets:

\[
\{ k \in \omega : s \upharpoonright k \in p \} \quad \text{or} \quad \{ t \in p : (\exists k \in \omega) \ t = s \upharpoonright k \},
\]

and we rely on the context to help the reader decide which set we mean.

A **branch** of \( p \) is either of the following:

- A function \( f : \omega \to \omega \) with \( f[n] \in p \) for all \( n \in \omega \).
- A maximal chain in the partial order \( (p, \subseteq) \). (As our trees do not have maximal elements, each such chain \( C \) determines a branch \( \bigcup C \) in the first sense, and conversely.)

We write \( [p] \) for the set of all branches of \( p \).

For any tree \( p \subseteq \omega^{< \omega} \) and any \( s \in p \) we write \( p[s] \) for the set \( \{ t \in p : t \supseteq s \text{ or } t \subseteq s \} \), and we write \( [s] \) for either of the following sets:

\[
\{ t \in p : s \subseteq t \} \quad \text{or} \quad \{ x \in [p] : s \subseteq x \}.
\]

---

5Except for the proof of Lemma [1.5] where we also allow trees with maximal elements, and even empty trees.
The stem of a tree $p$ is the shortest $s \in p$ with $|\text{succ}_p(s)| > 1$. (The trees we consider will never be branches, i.e., will always have finite stems.)

**Definition 1.1.**
- For trees $q, p$ we write $q \leq p$ if $q \subseteq p$ ("$q$ is stronger than $p$") and we say that "$q$ is a pure extension of $p$" ($q \leq_0 p$) if $q \leq p$ and $\text{stem}(q) = \text{stem}(p)$.
- A filter system $D$ is a family $(D_s)_{s \in \omega}^\omega$ of filters on $\omega$. (All our filters will contain the Fréchet filter of cofinite sets.) We write $D^+_t$ for the collection of $D_s$-positive sets (i.e., sets whose complement is not in $D_s$).
- We define $\mathbb{L}_D$ to be the set of all trees $p$ such that $\text{succ}_p(t) \in D^+_t$ for all $t \in p$ above the stem.
- The generic filter is determined by the generic branch $\tilde{\ell} = (\ell_i)_{i \in \omega} \in \omega^\omega$, called the generic real: $\{\tilde{\ell}\} = \bigcap_{p \in G} [p]$ or, equivalently, $\tilde{\ell} = \bigcup_{p \in G} \text{stem}(p)$.
- An ultrafilter system is a filter system consisting of ultrafilters. (Since all our filters contain the Fréchet filter, we only consider non-principal ultrafilters.)
- An ultralaver forcing is a forcing $\mathbb{L}_D$ defined from an ultrafilter system. The generic real for an ultralaver forcing is also called the ultralaver real.

Recall that a forcing notion $(P, \leq)$ is $\sigma$-centered if $P = \bigcup_n P_n$, where for all $n, k \in \omega$ and for all $p_1, \ldots, p_k \in P_n$ there is $q \leq p_1, \ldots, p_k$.

**Lemma 1.2.** All ultralaver forcings $\mathbb{L}_D$ are $\sigma$-centered (hence $\text{ccc}$).

**Proof.** Every finite set of conditions sharing the same stem has a common lower bound. ∎

**Lemma 1.3.** $\mathbb{L}_D$ is separative\[\text{\textcircled{1}}\]

**Proof.** If $q \nleq p$, then there is $s \in p \setminus q$. Now $p[s] \perp q$. ∎

If each $D_s$ is the Fréchet filter, then $\mathbb{L}_D$ is Laver forcing (often just written $\mathbb{L}$).

1.B. $M$-complete embeddings. Note that for all ultrafilter systems $\bar{D}$ we have:

Two conditions in $\mathbb{L}_{\bar{D}}$ are compatible if and only if their stems are comparable and, moreover, the longer stem is an element of the condition with the shorter stem.

**Lemma 1.5.** Let $M$ be countable\[\textit{\textcircled{2}}\] In $M$, let $\mathbb{L}_{\bar{D}^M}$ be an ultralaver forcing. Let $\bar{D}$ be (in $V$) a filter system extending $\bar{D}^M$. Then $\mathbb{L}_{\bar{D}^M}$ is an $M$-complete subforcing of $\mathbb{L}_{\bar{D}}$.

**Proof.** For any tree $T$, any filter system $\bar{E} = (E_s)_{s \in \omega}^\omega$, and any $s_0 \in T$ we define a sequence $(T^{\alpha}_{s, s_0})_{\alpha \in \omega_1}$ of "derivatives" (where we may abbreviate $T^{\alpha}_{s, s_0}$ to $T^{\alpha}$) as follows:

- $T^0 := T^{[s_0]}$.

\[\textit{\textcircled{3}}\]See page 248 for the definition.

\[\textit{\textcircled{4}}\]Here, we can assume that $M$ is a countable transitive model of a sufficiently large finite subset $\text{ZFC}^*$ of ZFC. Later, we will also use ord-transitive models instead of transitive ones, which does not make any difference as far as properties of $\mathbb{L}_D$ are concerned, as our arguments take place in transitive parts of such models.

\[\textit{\textcircled{5}}\]i.e., $D^M_s \subseteq D_s$ for all $s \in \omega^\omega$.

\[\textit{\textcircled{6}}\]Here we also allow empty trees and trees with maximal nodes.
Given $T^\alpha$, we let $T^{\alpha+1} := T^\alpha \setminus \bigcup\{[s] : s \in T^\alpha, s_0 \subseteq s, \text{succ}_{T^\alpha}(s) \notin E^+_s\}$, where $[s] := \{t : s \subseteq t\}$.

For limit ordinals $\delta > 0$ we let $T^\delta := \bigcap_{\alpha<\delta} T^\alpha$.

Then we have

(a) Each $T^\alpha$ is closed under initial segments. Also, $\alpha < \beta$ implies $T^\alpha \supseteq T^\beta$.

(b) There is an $\alpha_0 < \omega_1$ such that $T^{\alpha_0} = T^{\alpha_0+1} = T^\beta$ for all $\beta > \alpha_0$. We write $T^\infty$ or $T^{E,s_0}_E$ for $T^{\alpha_0}$.

(c) If $s_0 \in T^{E,s_0}_E$, then $T^{E,s_0}_E \in \mathbb{L}_E$ with stem $s_0$.

Conversely, if stem($T$) = $s_0$ and $T \in \mathbb{L}_E$, then $T^\infty = T$.

(d) If $T$ contains a tree $q \in \mathbb{L}_E$ with stem($q$) = $s_0$, then $T^\infty$ contains $q^\infty = q$, so in particular $s_0 \in T^\infty$.

(e) Thus, $T$ contains a condition in $\mathbb{L}_E$ with stem $s_0$ iff $s_0 \in T^{E,s_0}_E$.

(f) The computation of $T^\infty$ is absolute between any two models containing $T$ and $E$. (In particular, any transitive ZFC* model containing $T$ and $E$ will also contain $\alpha_0$.)

(g) Moreover, let $T \in M$, $\bar{E} \in M$, and let $\bar{E}'$ be a filter system extending $\bar{E}$ such that for all $s_0$ and all $A \in \mathcal{P}(\omega) \cap M$ we have $A \in (E_{s_0})^+$ iff $A \in (E'_{s_0})^+$. (In particular, this will be true for any $\bar{E}'$ extending $\bar{E}$, provided that each $E_{s_0}$ is an $M$-ultrafilter.)

Then for each $\alpha \in M$ we have $T^\alpha_{E,s_0} = T^\alpha_{E',s_0}$ (and hence $T^\alpha_{E',s_0} \in M$).

(Proved by induction on $\alpha$.)

Now let $A = \{p_i : i \in I\} \in M$ be a maximal antichain in $\mathbb{L}_{\bar{D},M}$ and assume (in $V$) that $q \in \mathbb{L}_{\bar{D}}$. Let $s_0 := \text{stem}(q)$.

We will show that $q$ is compatible with some $p_i$ (in $\mathbb{L}_{\bar{D}}$). This is clear if there is some $i$ with $s_0 \in p_i$ and stem($p_i$) $\subseteq s_0$, by (1.4). (In this case, $p_i \cap q$ is a condition in $\mathbb{L}_{\bar{D}}$ with stem $s_0$.)

So for the rest of the proof we assume that this is not the case, i.e.:

\begin{equation}
(1.6)
\text{There is no } i \text{ with } s_0 \in p_i \text{ and } \text{stem}(p_i) \subseteq s_0.
\end{equation}

Let $J := \{i \in I : s_0 \subseteq \text{stem}(p_i)\}$. We claim that there is $j \in J$ with stem($p_j$) $\in q$ (which as above implies that $q$ and $p_j$ are compatible).

Assume towards a contradiction that this is not the case. Then $q$ is contained in the following tree $T$:

\begin{equation}
(1.7)
T := (\omega_\omega)^{<\omega}\upharpoonright \bigcup_{j \in J} \text{stem}(p_j).
\end{equation}

Note that $T \in M$. In $V$ we have:

\begin{equation}
(1.8)
The tree $T$ contains a condition $q$ with stem $s_0$.
\end{equation}

So by (e) (applied in $V$), followed by (g), and again by (e) (now in $M$) we get:

\begin{equation}
(1.9)
The tree $T$ also contains a condition $p \in M$ with stem $s_0$.
\end{equation}

Now $p$ has to be compatible with some $p_i$. The sequences $s_0 = \text{stem}(p)$ and $\text{stem}(p_i)$ have to be comparable, so by (1.4) there are two possibilities:

\begin{enumerate}
\item $\text{stem}(p_i) \subseteq \text{stem}(p) = s_0 \in p_i$. We have excluded this case in our assumption (1.6).
\item $s_0 = \text{stem}(p) \subseteq \text{stem}(p_i) \in p$. So $i \in J$. By construction of $T$ (see (1.7)), we conclude $\text{stem}(p_i) \notin T$, contradicting $\text{stem}(p_i) \in p \subseteq T$ (see (1.9)). \qed
\end{enumerate}
1.C. Ultralaver kills strong measure zero. The following lemma already appears in [Bla88, Theorem 9]. We will give a proof below in Lemma 1.35.

Lemma 1.10. If $A$ is a finite set, $\alpha$ an $\mathbb{L}_D$-name, $p \in \mathbb{L}_D$, and $p \models \alpha \in A$, then there is $\beta \in A$ and a pure extension $q \leq_0 p$ such that $q \models \alpha = \beta$.

Definition 1.11. Let $\bar{\ell}$ be an increasing sequence of natural numbers. We say that $X \subseteq 2^\omega$ is smz with respect to $\bar{\ell}$ if there exists a sequence $(I_k)_{k \in \omega}$ of basic intervals of $2^\omega$ of measure $\leq 2^{-\bar{\ell}_k}$ (i.e., each $I_k$ is of the form $[s_k]$ for some $s_k \in 2^k$) such that $X \subseteq \bigcap_{m \in \omega} \bigcup_{k \geq m} I_k$.

Remark 1.12. It is well known and easy to see that the properties
- for all $\bar{\ell}$ there exists a sequence $(I_k)_{k \in \omega}$ of basic intervals of $2^\omega$ of measure $\leq 2^{-\bar{\ell}_k}$ such that $X \subseteq \bigcup_{k \in \omega} I_k$,
- for all $\bar{\ell}$ there exists a sequence $(I_k)_{k \in \omega}$ of basic intervals of $2^\omega$ of measure $\leq 2^{-\bar{\ell}_k}$ such that $X \subseteq \bigcap_{m \in \omega} \bigcup_{k \geq m} I_k$

are equivalent. Hence, a set $X$ is smz iff $X$ is smz with respect to all $\bar{\ell} \in \omega$.

The following lemma is a variant of the corresponding lemma (and proof) for Laver forcing (see for example [Jec03, Lemma 28.20]): Ultralaver makes old uncountable sets non-smz.

Lemma 1.13. Let $\bar{D}$ be a system of ultrafilters, and let $\bar{\ell}$ be the $\mathbb{L}_D$-name for the ultralaver real. Then each uncountable set $X \in V$ is forced to be non-smz (witnessed by the ultralaver real $\bar{\ell}$).

More precisely, the following holds:

\[(1.14) \quad |_{\mathbb{L}_D} \forall X \in V \cap [2^\omega]^{\aleph_1} \forall (x_k)_{k \in \omega} \subseteq 2^\omega \quad X \not\subseteq \bigcap_{m \in \omega} \bigcup_{k \geq m} [x_k[\ell_k]].\]

We first give two technical lemmas:

Lemma 1.15. Let $p \in \mathbb{L}_D$ with stem $s \in \omega^{<\omega}$, and let $x$ be an $\mathbb{L}_D$-name for a real in $2^\omega$. Then there exists a pure extension $q \leq_0 p$ and a real $\tau \in 2^\omega$ such that for every $n \in \omega$,

\[(1.16) \quad \{ i \in \text{succ}_q(s) : q^{[s^{-i}]} \models x^n = \tau^n \} \in D_s.\]

Proof. For each $i \in \text{succ}_p(s)$, let $q_i \leq_0 p^{[s^{-i}]}$ be such that $q_i$ decides $x^n$, i.e., there is a $t_i$ of length $i$ such that $q_i \models x^{[i]} = t_i$ (this is possible by Lemma 1.10).

Now we define the real $\tau \in 2^\omega$ as the $D_s$-limit of the $t_i$'s. In more detail, for each $n \in \omega$ there is a (unique) $\tau_n \in 2^n$ such that $\{ i : t_i^n = \tau_n \} \in D_s$; since $D_s$ is a filter, there is a real $\tau \in 2^\omega$ with $\tau^n = \tau_n$ for each $n$. Finally, let $q := \bigcup_i q_i$. $\square$

Lemma 1.17. Let $p \in \mathbb{L}_D$ with stem $s$, and let $(x_k)_{k \in \omega}$ be a sequence of $\mathbb{L}_D$-names for reals in $2^\omega$. Then there exists a pure extension $q \leq_0 p$ and a family of reals $(\tau_\eta)_{\eta \in q, \eta \geq s} \subseteq 2^\omega$ such that for each $\eta \in q$ above $s$ and every $n \in \omega$,

\[(1.18) \quad \{ i \in \text{succ}_q(s) : q^{[\eta^{-i}]} \models x^{[\eta]} = \tau_\eta^n \} \in D_\eta.\]

Proof. We apply Lemma 1.15 to each node $\eta$ in $p$ above $s$ (and to $x^{[\eta]}$) separately. We first get a $p_1 \leq_0 p$ and a $\tau_s \in 2^\omega$; for every immediate successor $\eta \in \text{succ}_{p_1}(s)$, we get $q_\eta \leq_0 p_1^{[\eta]}$ and a $\tau_\eta \in 2^\omega$, and let $p_2 := \bigcup_\eta q_\eta$. In this way, we get a (fusion) sequence $(p, p_1, p_2, \ldots)$ and let $q := \bigcap_k p_k$. $\square$
Proof of Lemma 1.13. We want to prove (1.14). Assume towards a contradiction that $X$ is an uncountable set in $V$ and that $\langle x_k \rangle_{k \in \omega}$ is a sequence of names for reals in $2^\omega$ and $p \in \mathbb{L}_D$ such that

$$p \Vdash X \subseteq \bigcap_{m \in \omega} \bigcup_{k \geq m} [x_k[\ell_k]].$$

Let $s \in \omega^{<\omega}$ be the stem of $p$.

By Lemma 1.17, we can fix a pure extension $q \leq p$ and a family $(\tau_\eta)_{\eta \in q, \eta \supseteq s} \subseteq 2^\omega$ such that for each $\eta \in q$ above the stem $s$ and every $n \in \omega$, condition (1.18) holds.

Since $X$ is (in $V$ and) uncountable, we can find a real $x^* \in X$ which is different from each real in the countable family $(\tau_\eta)_{\eta \in q, \eta \supseteq s}$. More specifically, we can pick a family of natural numbers $(n_\eta)_{\eta \in q, \eta \supseteq s}$ such that $x^*[n_\eta] \neq \tau_\eta[n_\eta]$ for any $\eta$.

We can now find $r \leq_0 q$ such that:

- For all $\eta \in r$ above $s$ and all $i \in \text{succ}_r(\eta)$ we have $i > n_\eta$.
- For all $\eta \in r$ above $s$ and all $i \in \text{succ}_r(\eta)$ we have $r[^{\eta\smallsetminus i}] \Vdash x_\eta[n_\eta] = \tau_\eta[n_\eta] = x^*[n_\eta]$, contradicting (1.19).

So for all $\eta \in r$ above $s$ we have, writing $k$ for $|\eta|$, that $r[^{\eta\smallsetminus i}]$ forces $x^* \notin [x_k[n_\eta]] \supseteq [x_k[\ell_k]]$. We conclude that $r$ forces $x^* \notin \bigcup_{k \geq |s|} [x_k[\ell_k]]$, contradicting (1.19).

Corollary 1.20. Let $\langle t_k \rangle_{k \in \omega}$ be a dense subset of $2^\omega$.

Let $D$ be a system of ultrafilters, and let $\bar{\ell}$ be the $\mathbb{L}_D$-name for the ultralaver real. Then the set

$$H := \bigcap_{m \in \omega} \bigcup_{k \geq m} [t_k[\ell_k]]$$

is forced to be a comeager set with the property that $H$ does not contain any translate of any old uncountable set.

Pawlikowski’s Theorem 1.2 gives us:

Corollary 1.21. There is a canonical name $F$ for a closed null set such that $X + F$ is positive for all uncountable $X$ in $V$.

In particular, no uncountable ground model set is smz in the ultralaver extension.

1.D. Thin sets and strong measure zero. For the notion of a “(very) thin” set, we use an increasing function $B^*(k)$ (the function we use will be described in Corollary 2.2). We will assume that $\ell^* = (\ell^*_k)_{k \in \omega}$ is an increasing sequence of natural numbers with $\ell^*_{k+1} \gg B^*(k)$. (We will later use a subsequence of the ultralaver real $\bar{\ell}$ as $\ell^*$; see Lemma 1.22.)

Definition 1.22. For $X \subseteq 2^\omega$ and $k \in \omega$ we write $X | [\ell^*_k, \ell^*_{k+1})$ for the set $\{x | [\ell^*_k, \ell^*_{k+1}) : x \in X\}$. We say that

- $X \subseteq 2^\omega$ is “very thin with respect to $\ell^*$ and $B^*$” if there are infinitely many $k$ with $|X | [\ell^*_k, \ell^*_{k+1})| \leq B^*(k)$.
- $X \subseteq 2^\omega$ is “thin with respect to $\ell^*$ and $B^*$” if $X$ is the union of countably many very thin sets.

Note that the family of thin sets is a $\sigma$-ideal, while the family of very thin sets is not even an ideal. Also, every very thin set is covered by a closed very thin (in particular, nowhere dense) set. In particular, every thin set is meager and the ideal of thin sets is a proper ideal.
Lemma 1.23. Let $B^*$ be an increasing function. Let $\ell \uparrow \ell$ be an increasing sequence of natural numbers. We define a subsequence $\ell^* \uparrow \ell$ in the following way: $\ell^*_k = \ell_{n_k}$ where $n_{k+1} - n_k = B^*(k) \cdot 2^{\ell_k}$.

Then we get: If $X$ is thin with respect to $\ell^*$ and $B^*$, then $X$ is smz with respect to $\ell$.

Proof. Assume that $X = \bigcup_{i \in \omega} Y_i$; each $Y_i$ very thin with respect to $\ell^*$ and $B^*$. Let $(X_j)_{j \in \omega}$ be an enumeration of $\{Y_i : i \in \omega\}$, where each $Y_i$ appears infinitely often. So $X \subseteq \bigcap_{m \in \omega} \bigcup_{j \geq m} X_j$.

By induction on $j \in \omega$, we find for all $j > 0$ some $k_j > k_{j-1}$ such that

$$|X_j| [\ell^*_k, \ell^*_n] \leq B^*(k_j); \quad \text{hence} \quad |X_j| [0, \ell^*_k+1] \leq B^*(k_j) \cdot 2^{\ell^*_k} = n_{k_j+1} - n_{k_j}.$$ 

So we can enumerate $X_j [0, \ell^*_k+1)$ as $(s_i)_{n_{k_j} \leq i < n_{k_j} + 1}$. Hence $X_j$ is a subset of $\bigcup_{n_{k_j} \leq i < n_{k_j} + 1} [s_i]$; and each $s_i$ has length $\ell^*_{k_j+1} \geq \ell_i$, since $\ell^*_k = \ell_{n_{k_j} + 1}$ and $i < n_{k_j+1}$. This implies

$$X \subseteq \bigcap_{m \in \omega} \bigcup_{j \geq m} X_j \subseteq \bigcap_{m \in \omega} \bigcup_{i \geq m} [s_i].$$

Hence $X$ is smz with respect to $\ell$. \qed

Lemma [1.13] and Lemma [1.23] yield:

Corollary 1.24. Let $B^*$ be an increasing function. Let $\mathcal{D}$ be a system of ultrafilters, and $\ell$ the name for the ultralaver real. Let $\ell^*$ be constructed from $B^*$ and $\ell$ as in Lemma [1.23].

Then $L_D$ forces that for every uncountable $X \subseteq 2^\omega$:

- $X$ is not smz with respect to $\ell$.
- $X$ is not thin with respect to $\ell^*$ and $B^*$.

1.6. Ultralaver and preservation of Lebesgue positivity. It is well known that both Laver forcing and random forcing preserve Lebesgue positivity. In fact, they satisfy a stronger property that is preserved under countable support iterations. (So, in particular, a countable support iteration of Laver and random also preserves positivity.)

Ultralaver forcing $\mathbb{L}_D$ will in general not preserve positivity. Indeed, if all ultrafilters $D_s$ are equal to the same ultrafilter $D^*$, then the range $L := \{\ell_0, \ell_1, \ldots\} \subseteq \omega$ of the ultralaver real $\ell$ will diagonalize $D^*$, so every ground model real $x \in 2^\omega$ (viewed as a subset of $\omega$) will either almost contain $L$ or be almost disjoint to $L$, which implies that the set $2^\omega \cap V$ of old reals is covered by a null set in the extension. However, later in this paper it will become clear that if we choose the ultrafilters $D_s$ in a sufficiently generic way, then many old positive sets will stay positive. More specifically, in this section we will show (Lemma [1.30]): If $\mathbb{D}^M$ is an ultrafilter system in a countable model $M$ and $r$ a random real over $M$, then we can find an extension $\mathbb{D}$ such that $L_D$ forces that $r$ remains random over $M[H^M]$ (where $H^M$ denotes the $\mathbb{L}_D$-name for the restriction of the $\mathbb{L}_D$-generic filter $H$ to $\mathbb{L}_{D^M} \cap M$). Additionally, some “side conditions” are met, which are necessary to preserve the property in forcing iterations.

In Section 3.D we will see how to use this property to preserve randoms in limits.
The setup we use for preservation of randomness is basically the notation of “Case A” preservation introduced in [She98, Ch.XVIII]; see also [Go93, GK06] or the textbook [B.J95, 6.1.B]:

**Definition 1.25.** We write clopen for the collection of clopen sets on $2^\omega$. We say that the function $Z : \omega \to \text{clopen}$ is a code for a null set if the measure of $Z(n)$ is at most $2^{-n}$ for each $n \in \omega$.

For such a code $Z$, the set nullset($Z$) coded by $Z$ is

$$\text{nullset}(Z) := \bigcap_n \bigcup_{k \geq n} Z(k).$$

The set nullset($Z$) is obviously a null set, and it is well known that every null set is contained in such a set nullset($Z$).

**Definition 1.26.** For a real $r$ and any code $Z$, we define $Z \sqsubseteq_n r$ by

$$(\forall k \geq n) r \notin Z(k).$$

We write $Z \sqsubseteq r$ if $Z \sqsubseteq_n r$ holds for some $n$, i.e., if $r \notin \text{nullset}(Z)$.

For later reference, we record the following trivial fact:

$$p \vDash Z \sqsubseteq r \text{ iff there is a name } \bar{z} \text{ for an element of } \omega \text{ such that}$$

$$p \vDash Z \sqsubseteq \bar{z}. \quad (1.27)$$

Let $P$ be a forcing notion, and let $Z$ be a $P$-name of a code for a null set. An interpretation of $Z$ below $p$ is some code $Z^*$ such that there is a sequence $p = p_0 \geq p_1 \geq p_2 \geq \ldots$ such that $p_m$ forces $Z|_m = Z^*|_m$. Usually we demand (which allows a simpler proof of the preservation theorem at limit stages) that the sequence $(p_0, p_1, \ldots)$ is inconsistent, i.e., $p$ forces that there is an $m$ such that $p_m \notin G$. Note that whenever $P$ adds a new $\omega$-sequence of ordinals, we can find such an interpretation for any $Z$.

If $\bar{Z} = (Z_1, \ldots, Z_m)$ is a tuple of names of codes for null sets, then an interpretation of $\bar{Z}$ below $p$ is some tuple $(Z_1^*, \ldots, Z_m^*)$ such that there is a single sequence $p = p_0 \geq p_1 \geq p_2 \geq \ldots$ interpreting each $Z_i$ as $Z_i^*$.

We now turn to preservation of Lebesgue positivity:

**Definition 1.28.**

1. A forcing notion $P$ preserves Borel outer measure if $P$ forces $\text{Leb}^*(A^V) = \text{Leb}(A^V|G\bar{R})$ for every code $A$ for a Borel set. ($\text{Leb}^*$ denotes the outer Lebesgue measure, and for a Borel code $A$ and a set-theoretic universe $V$, $A^V$ denotes the Borel set coded by $A$ in $V$.)

2. $P$ strongly preserves randomness if the following holds: Let $N \prec H(\chi^*)$ be countable for a sufficiently large regular cardinal $\chi^*$, let $P, p, \bar{Z} = (Z_1, \ldots, Z_m) \in N$, let $p \in P$ and let $r$ be random over $N$. Assume that in $N$, $\bar{Z}$ is an interpretation of $\bar{Z}$, and assume $Z_i^* \sqsubseteq_{k_i} r$ for each $i$. Then there is an $N$-generic $q \leq p$ forcing that $r$ is still random over $N[G]$ and, moreover, $Z_i \sqsubseteq_{k_i} r$ for each $i$. (In particular, $P$ has to be proper.)

3. Assume that $P$ is absolutely definable. $P$ strongly preserves randomness over countable models if (2) holds for all countable (transitive$^{10}$) models $N$ of ZFC$^*$.

$^{10}$Later we will introduce ord-transitive models, and it is easy to see that it does not make any difference whether we demand transitive or not; this can be seen using a transitive collapse.
It is easy to see that these properties are increasing in strength. (Of course (3) ⇒ (2) works only if ZFC* is satisfied in $H(\chi^*)$.)

In [KS05] it is shown that (1) implies (3), provided that $P$ is nep (“non-elementary proper”, i.e., nicely definable and proper with respect to countable models). In particular, every Suslin ccc forcing notion such as random forcing, and also many tree forcing notions including Laver forcing, are nep. However, $\mathbb{L}_D$ is not nicely definable in this sense, as its definition uses ultrafilters as parameters.

**Lemma 1.29.** Both Laver forcing and random forcing strongly preserve randomness over countable models.

**Proof.** For random forcing, this is easy and well known (see, e.g., [BJ95, 6.3.12]).

For Laver forcing: By the above, it is enough to show (1). This was done by Woodin (unpublished) and Judah-Shelah [JS90]. A nicer proof (including a variant of (2)) is given by Pawlikowski [Paw96b].

Ultralaver will generally not preserve Lebesgue positivity, let alone randomness. However, we get the following “local” variant of strong preservation of randomness (which will be used in the preservation theorem 3.33). The rest of this section will be devoted to the proof of the following lemma.

**Lemma 1.30.** Assume that $M$ is a countable model, $\bar{D}^M$ an ultrafilter system in $M$ and $r$ a random real over $M$. Then there is (in $V$) an ultrafilter system $\bar{D}$ extending $\bar{D}^M$ such that the following holds:

- $p \in \mathbb{L}_D M$,
- in $M$, $\bar{Z} = (Z_1, \ldots, Z_m)$ is a sequence of $\mathbb{L}_D M$-names for codes for null sets and $Z_1^*, \ldots, Z_m^*$ are interpretations under $p$, witnessed by a sequence $(p_n)_{n \in \omega}$ with strictly increasing stems,
- $Z_i^* \sqsubset k_i r$ for $i = 1, \ldots, m$,

then there is a $q \leq p$ in $\mathbb{L}_D$ forcing that

- $r$ is random over $M[G^M]$,
- $Z_i \sqsubset k_i r$ for $i = 1, \ldots, m$.

For the proof of this lemma, we will use the following concepts:

**Definition 1.31.** Let $p \subseteq \omega^{<\omega}$ be a tree. A “front name below $p$” is a function $h : F \to \text{clopens}$, where $F \subseteq p$ is a front (a set that meets every branch of $p$ in a unique point). (For notational simplicity we also allow $h$ to be defined on elements $\notin p$. This way, every front name below $p$ is also a front name below $q$ whenever $q \leq p$.)

If $h$ is a front name and $\bar{D}$ is any filter system with $p \in \mathbb{L}_D$, we define the corresponding $\mathbb{L}_D$-name (in the sense of forcing) $\bar{z}^h$ by

$$\bar{z}^h := \{(\bar{y}, p^h s) : s \in F, y \in h(s)\}.$$  

---

11This implies, by Lemma 1.5, that the $\mathbb{L}_D$-generic filter $G$ induces an $\mathbb{L}_D M$-generic filter over $M$, which we call $G^M$.

12Recall that $\text{nullset}(Z) = \bigcap_n \bigcup_{k \geq n} Z(k)$ is a null set in the extension.

13It is enough to assume that the lengths of the stems diverge to infinity; any thin enough subsequence will then have strictly increasing stems and will still interpret each $Z_i$ as $Z_i^*$. 

14Instead of \text{clopens} we may also consider other ranges of front names, such as the class of all ordinals, or the set $\omega$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
(This does not depend on the $\bar{D}$ we use, since we set $\bar{y} := \{(\bar{x}, \omega^{<\omega}) : x \in y\}$.)

Up to forced equality, the name $\bar{z}^h$ is characterized by the fact that $p^{[s]}$ forces (in any $L_{\bar{D}}$) that $\bar{z}^h = h(s)$ for every $s$ in the domain of $h$.

Note that the same object $h$ can be viewed as a front name below $p$ with respect to different forcings $L_{\bar{D}_1}, L_{\bar{D}_2}$, as long as $p \in L_{\bar{D}_1} \cap L_{\bar{D}_2}$.

**Definition 1.33.** Let $p \subseteq \omega^{<\omega}$ be a tree. A “continuous name below $p$” is either of the following:

- An $\omega$-sequence of front names below $p$.
- A $\subseteq$-increasing function $g : p \rightarrow \text{CLOPEN}^{<\omega}$ such that $\lim_{n \rightarrow \infty} \text{lh}(g(c|n)) = \infty$ for every branch $c \in [p]$.

For each $n$, the set of minimal elements in $\{s \in p : \text{lh}(g(s)) > n\}$ is a front, so each continuous name in the second sense naturally defines a name in the first sense, and conversely. Being a continuous name below $p$ does not involve the notion of $\models$ nor does it depend on the filter system $\bar{D}$.

If $g$ is a continuous name and $\bar{D}$ is any filter system, we can again define the corresponding $L_{\bar{D}}$-name $Z^g$ (in the sense of forcing). We leave a formal definition of $Z^g$ to the reader and content ourselves with this characterization:

$$(1.34) \quad (\forall s \in p) : p^{[s]} \models_{L_{\bar{D}}} g(s) \subseteq Z^g.$$

Note that a continuous name below $p$ naturally corresponds to a continuous function $F : [p] \rightarrow \text{CLOPEN}^{\omega}$, and $Z^g$ is forced (by $p$) to be the value of $F$ at the generic real $\ell$.

**Lemma 1.35.** $L_{\bar{D}}$ has the following “pure decision properties”:

1. Whenever $y$ is a name for an element of CLOPEN, $p \in L_{\bar{D}}$, then there is a pure extension $p_1 \leq_0 p$ such that $y = z^h$ (is forced) for a front name $h$ below $p_1$.

2. Whenever $Y$ is a name for a sequence of elements of CLOPEN, $p \in L_{\bar{D}}$, then there is a pure extension $q \leq_0 p$ such that $Y = Z^g$ (is forced) for some continuous name $g$ below $q$.

3. (This is Lemma 1.10) If $A$ is a finite set, $\alpha$ a name, $p \in L_{\bar{D}}$, and $p$ forces $\alpha \in A$, then there is $\beta \in A$ and a pure extension $q \leq_0 p$ such that $q \models \alpha = \beta$.

**Proof.** Let $p \in L_{\bar{D}}$, $s_0 := \text{stem}(p)$, and $y$ be a name for an element of CLOPEN.

We call $t \in p$ a “good node in $p$” if $y$ is a front name below $p^{[t]}$ (more formally, forced to be equal to $z^h$ for a front name $h$). We can find $p_1 \leq_0 p$ such that for all $t \in p_1$ above $s_0$: If there is $q \leq_0 p_1^{[t]}$ such that $t$ is good in $q$, then $t$ is already good in $p_1$.

We claim that $s_0$ is now good (in $p_1$). Note that for any bad node $s$ the set $\{ t \in \text{succ}_{p_1}(s) : t \text{ bad}\}$ is in $D_s^+$. Hence, if $s_0$ is bad, we can inductively construct $p_2 \leq_0 p_1$ such that all nodes of $p_2$ are bad nodes in $p_1$. Now let $q \leq p_2$ decide $y$, $s := \text{stem}(q)$. Then $q \leq_0 p_1^{[s]}$, so $s$ is good in $p_1$, a contradiction. This finishes the proof of (1).

To prove (2), we first construct $p_1$ as in (1) with respect to $y_0$. This gives a front $F_1 \subseteq p_1$ deciding $y_0$. Above each node in $F_1$ we now repeat the construction from (1) with respect to $y_1$, yielding $p_2$, etc. Finally, $q := \bigcap_n p_n$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
To prove \(\text{(3)}\): Similar to \(\text{(1)}\), we can find \(p_1 \leq_0 p\) such that for each \(t \in p_1\), if there is a pure extension of \(p_1\) deciding \(q\), then \(p_1\) decides \(q\). In this case we again call \(t\) good. Since there are only finitely many possibilities for the value of \(q\), any bad node \(t\) has \(D_t^+\) many bad successors. So if the stem of \(p_1\) is bad, we can again reach a contradiction as in \(\text{(1)}\). \(\square\)

**Corollary 1.36.** Let \(\bar{D}\) be a filter system, and let \(G \subseteq \mathbb{L}_D\) be generic. Then every \(Y \in \text{clopenn}^\omega\) in \(V[G]\) is the evaluation of a continuous name \(Z^g\) by \(G\).

**Proof.** In \(V\), fix a \(p \in \mathbb{L}_D\) and a name \(Y\) for an element of \(\text{clopenn}^\omega\). We can find \(q \leq_0 p\) and a continuous name \(g\) below \(q\) such that \(q \Vdash Y = Z^g\). \(\square\)

We will need the following modification of the concept of “continuous names”.

**Definition 1.37.** Let \(p \subseteq \omega^\omega\) be a tree, and let \(b \in [p]\) be a branch. An “almost continuous name below \(p\) (with respect to \(b\))” is a \(\subseteq\)-increasing function \(g : p \to \text{clopenn}^\omega\) such that \(\lim_{n \to \infty} \ell(h(g(c)|n)) = \infty\) for every branch \(c \in [p]\), except possibly for \(c = b\).

Note that “except possibly for \(c = b\)” is the only difference between this definition and the definition of a continuous name.

Since for any \(\bar{D}\) it is forced\(^15\) that the generic real (for \(\mathbb{L}_D\)) is not equal to the exceptional branch \(b\), we again get a name \(Z^g\) of a function in \(\text{clopenn}^\omega\) satisfying

\[ (\forall s \in p) : p|s\ Vdash_{\mathbb{L}_D} g(s) \subseteq Z^g. \]

An almost continuous name naturally corresponds to a continuous function \(F\) from \([p] \setminus \{b\}\) into \(\text{clopenn}^\omega\).

Note that being an almost continuous name is a very simple combinatorial property of \(g\) which does not depend on \(\bar{D}\), nor does it involve the notion \(\Vdash\). Thus, the same function \(g\) can be viewed as an almost continuous name for two different forcing notions \(\mathbb{L}_{D_1}, \mathbb{L}_{D_2}\) simultaneously.

**Lemma 1.38.** Let \(\bar{D}\) be a system of filters (not necessarily ultrafilters).

Assume that \(\bar{p} = (p_n)_{n \in \omega}\) witnesses that \(Y^*\) is an interpretation of \(Y\) and that the lengths of the stems of the \(p_n\) are strictly increasing\(^16\). Then there exists a sequence \(\bar{q} = (q_n)_{n \in \omega}\) such that

1. \(q_0 \geq q_1 \geq \cdots\)
2. \(q_n \leq p_n\) for all \(n\).
3. \(\bar{q}\) also interprets \(Y\) as \(Y^*\). (This follows from the previous two statements.)
4. \(Y\) is almost continuous below \(q_0\), i.e., there is an almost continuous name \(g\) such that \(q_0\) forces \(Y = Z^g\).
5. \(Y\) is almost continuous below \(q_n\), for all \(n\). (This follows from the previous statement.)

**Proof.** Let \(b\) be the branch described by the stems of the conditions \(p_n\):

\[ b := \{ s : (\exists n) s \subseteq \text{stem}(p_n) \}. \]

We now construct a condition \(q_0\). For every \(s \in b\) satisfying \(\text{stem}(p_n) \subseteq s \subseteq \text{stem}(p_{n+1})\) we set \(\text{succ}_{q_0}(s) = \text{succ}_{p_n}(s)\), and for all \(t \in \text{succ}_{q_0}(s)\) except for the

\(^15\)This follows from our assumption that all our filters contain the Fréchet filter.

\(^16\)It is easy to see that for every \(\mathbb{L}_D\)-name \(Y\) we can find such \(\bar{p}\) and \(Y^*\): First find \(\bar{p}\) which interprets both \(Y\) and \(\ell\), and then thin out to get a strictly increasing sequence of stems.
one in b we let \( q_0[t] \leq p_n[t] \) be such that \( Y \) is continuous below \( q_0[t] \). We can do this by Lemma 1.35(2).

Now we set

\[ q_n := p_n \cap q_0 = q_0^{[\text{stem}(p_n)]} \leq p_n. \]

This takes care of (1) and (2). Now we show (4): Any branch \( c \) of \( q_0 \) not equal to \( b \) must contain a node \( s \prec k \notin b \) with \( s \in b \), so \( c \) is a branch in \( q_0[s^{\prec}k] \), below which \( Y \) is continuous. \( \square \)

The following lemmas and corollaries are the motivation for considering continuous and almost continuous names.

**Lemma 1.39.** Let \( \bar{D} \) be a system of filters (not necessarily ultrafilters). Let \( p \in \mathbb{L}_{\bar{D}} \), let \( b \) be a branch, and let \( g : p \to \text{CLOPEN}^{<\omega} \) be an almost continuous name below \( p \) with respect to \( b \); write \( Z^g \) for the associated \( \mathbb{L}_{\bar{D}} \)-name.

Let \( r \in 2^{<\omega} \) be a real, \( n_0 \in \omega \). Then the following are equivalent:

1. \( p \Vdash_{\mathbb{L}_{\bar{D}}} r \notin \bigcup_{n \geq n_0} Z^g(n) \), i.e., \( Z^g \in n_0 \).
2. For all \( n \geq n_0 \) and all \( s \in p \) for which \( g(s) \) has length \( > n \), we have \( r \notin g(s)(n) \).

Note that (2) does not mention the notion \( \Vdash \) and does not depend on \( \bar{D} \).

**Proof.** \( \neg(2) \Rightarrow \neg(1) \): Assume there is \( s \in p \) for which \( g(s) = (C_0, \ldots, C_n, \ldots, C_k) \) and \( r \in C_n \). Then \( p[s] \) forces that the generic sequence \( Z^g = (Z(0), Z(1), \ldots) \) starts with \( C_0, \ldots, C_n \), so \( p[s] \) forces \( r \in Z^g(n) \).

\( \neg(1) \Rightarrow \neg(2) \): Assume that \( p \) does not force \( r \notin \bigcup_{n \geq n_0} Z^g(n) \). So there is a condition \( q \leq p \) and some \( n \geq n_0 \) such that \( q \Vdash r \in Z^g(n) \). By increasing the stem of \( q \), if necessary, we may assume that \( s := \text{stem}(q) \) is not on \( b \) (the “exceptional” branch) and that \( g(s) \) already has length \( > n \). Let \( C_n := g(s)(n) \) be the \( n \)-th entry of \( g(s) \), so \( p[s] \) already forces \( Z^g(n) = C_n \). Now \( q[s] \leq p[s] \), and \( q[s] \) forces the following statements: \( r \in Z^g(n), Z^g(n) = C_n \). Hence \( r \in C_n \), so (2) fails. \( \square \)

**Corollary 1.40.** Let \( \bar{D}_1 \) and \( \bar{D}_2 \) be systems of filters, and assume that \( p \) is in \( \mathbb{L}_{\bar{D}_1} \cap \mathbb{L}_{\bar{D}_2} \). Let \( g : p \to \text{CLOPEN}^{<\omega} \) be an almost continuous name of a sequence of clopen sets, and let \( Z^g_1 \) and \( Z^g_2 \) be the associated \( \mathbb{L}_{\bar{D}_1} \)-name and \( \mathbb{L}_{\bar{D}_2} \)-name, respectively.

Then for any real \( r \) and \( n \in \omega \) we have

\[ p \Vdash_{\mathbb{L}_{\bar{D}_1}} Z^g_1 \in n r \iff p \Vdash_{\mathbb{L}_{\bar{D}_2}} Z^g_2 \in n r. \]

(We will use this corollary for the special case that \( \mathbb{L}_{\bar{D}_1} \) is an ultralaver forcing and \( \mathbb{L}_{\bar{D}_2} \) is Laver forcing.)

**Lemma 1.41.** Let \( \bar{D}_1 \) and \( \bar{D}_2 \) be systems of filters, and assume that \( p \) is in \( \mathbb{L}_{\bar{D}_1} \cap \mathbb{L}_{\bar{D}_2} \). Let \( g : p \to \text{CLOPEN}^{<\omega} \) be a continuous name of a sequence of clopen sets, let \( F \subseteq p \) be a front and let \( h : F \to \omega \) be a front name. Again we will write \( Z^g_1, Z^g_2 \) for the associated names of codes for null sets, and we will write \( \eta_1 \) and \( \eta_2 \) for the associated \( \mathbb{L}_{\bar{D}_1} \)- and \( \mathbb{L}_{\bar{D}_2} \)-names, respectively, of natural numbers.

Then for any real \( r \) we have

\[ p \Vdash_{\mathbb{L}_{\bar{D}_1}} Z^g_1 \in \eta_1 r \iff p \Vdash_{\mathbb{L}_{\bar{D}_2}} Z^g_2 \in \eta_2 r. \]
Proof. Assume $p \Vdash_{L_{D_1}} Z_1^g \subseteq B_1 \ r$. So for each $s \in F$ we have $p^{[s]} \Vdash_{L_{D_1}} Z_1^g \subseteq h(s) \ r$. By Corollary 1.40 we also have $p^{[s]} \Vdash_{L_{D_2}} Z_2^g \subseteq h(s) \ r$. So also $p^{[s]} \Vdash_{L_{D_2}} Z_2^g \subseteq n_2 \ r$ for each $s \in F$. Hence $p \Vdash_{L_{D_2}} Z_2^g \subseteq n_2 \ r$.

Corollary 1.42. Assume $q \in \mathbb{L}$ forces in Laver forcing that $Z^{g_k} \subseteq r$ for $k = 1, 2, \ldots$, where each $g_k$ is a continuous name of a code for a null set. Then there is a Laver condition $q' \leq_0 q$ such that for all filter systems $D$ we have:

If $q' \in L_D$, then $q'$ forces (in $L_D$) that $Z^{g_k} \subseteq r$ for all $k$.

Proof. By 1.27 we can find a sequence $(\eta_k)_{k=1}^{\infty}$ of $\mathbb{L}$-names such that $q \Vdash Z^{g_k} \subseteq \eta_k \ r$ for each $k$. By Lemma 1.35(2) we can find $q' \leq_0 q$ such that this sequence is continuous below $q'$. Since each $\eta_k$ is now a front name below $q'$, we can apply the previous lemma.

Lemma 1.43. Let $M$ be a countable model, $r \in 2^\omega$, $\bar{D}^M \in M$ an ultrafilter system, $\bar{D}$ a filter system extending $\bar{D}^M$, and $q \in L_D$. For any $V$-generic filter $G \subseteq L_D$ we write $G^M$ for the ($M$-generic, by Lemma 1.15) filter on $L_{D^M}$.

The following are equivalent:

1. $q \Vdash_{L_D} r$ is random over $M[G^M]$.
2. For all names $Z \in M$ of codes for null sets, $q \Vdash_{L_D} Z \subseteq r$.
3. For all continuous names $g \in M$, $q \Vdash_{L_D} Z^g \subseteq r$.

Proof. (1)$\iff$(2) holds because every null set is contained in a set of the form $\text{nullset}(Z)$, for some code $Z$.

(2)$\iff$(3): Every code for a null set in $M[G^M]$ is equal to $Z^g[G^M]$, for some $g \in M$, by Corollary 1.36.

The following lemma may be folklore. Nevertheless, we prove it for the convenience of the reader.

Lemma 1.44. Let $r$ be random over a countable model $M$ and $A \in M$. Then there is a countable model $M' \supseteq M$ such that $A$ is countable in $M'$, and $r$ is still random over $M'$.

Proof. We will need the following forcing notions, all defined in $M$:

$$
\begin{array}{ccc}
M & \xrightarrow{C} & MC \\
B_1 \downarrow & & B_2 \\
MB_1 & \xrightarrow{P = C \ast B_2 / B_1} & M^{C \ast B_2}
\end{array}
$$

- Let $C$ be the forcing that collapses the cardinality of $A$ to $\omega$ with finite conditions.
- Let $B_1$ be random forcing (trees $T \subseteq 2^{<\omega}$ of positive measure).
- Let $B_2$ be the $C$-name of random forcing.
- Let $i : B_1 \rightarrow C \ast B_2$ be the natural complete embedding $T \mapsto (1_C, T)$.
- Let $P$ be a $B_1$-name for the forcing $C \ast B_2 / i[G_{B_1}]$, the quotient of $C \ast B_2$ by the complete subforcing $i[B_1]$.

The random real $r$ is $B_1$-generic over $M$. In $M[r]$ we let $P := P[r]$. Now let $H \subseteq P$ be generic over $M[r]$. Then $r \ast H \subseteq B_1 \ast P \simeq C \ast B_2$ induces an $M$-generic
filter $J \subseteq C$ and an $M[J]$-generic filter $K \subseteq B_2[J]$. It is easy to check that $K$ interprets the $B_2$-name of the canonical random real as the given random real $r$.

\[
\begin{array}{c}
M \xrightarrow{J} M[J] \\
\downarrow r \quad \downarrow K \\
M[r] \xrightarrow{H} M[r][H]
\end{array}
\]

Hence $r$ is random over the countable model $M' := M[J]$ and $A$ is countable in $M'$.

**Proof of Lemma 1.30** We will first describe a construction that deals with a single triple $(\tilde{p}, \tilde{Z}, \tilde{Z}^*)$ (where $\tilde{p}$ is a sequence of conditions with strictly increasing stems which interprets $Z$ as $\tilde{Z}^*$); this construction will yield a condition $q' = q'(\tilde{p}, \tilde{Z}, \tilde{Z}^*)$. We will then show how to deal with all possible triples.

Let $p$ be a condition, and let $\tilde{p} = (p_k)_{k \in \omega}$ be a sequence interpreting $Z$ as $\tilde{Z}^*$, where the lengths of the stems of $p_k$ are strictly increasing and $p_0 = p$. It is easy to see that it is enough to deal with a single null set, i.e., $m = 1$, and with $k_1 = 0$. We write $Z$ and $Z^*$ instead of $Z_1$ and $Z_1^*$.

Using Lemma 1.38 we may (strengthening the conditions in our interpretation) assume (in $M$) that the sequence $(\tilde{Z}(k))_{k \in \omega}$ is almost continuous, witnessed by $g : p \to \text{clop} \cap_\omega \omega$. By Lemma 1.41 we can find a model $M' \supseteq M$ such that $(\omega_1^M)$ is countable in $M'$, but $r$ is still random over $M'$.

We now work in $M'$. Note that $g$ still defines an almost continuous name, which we again call $Z$.

Each filter in $D^M_s$ is now countably generated; let $A_s$ be a pseudo-intersection of $D^M_s$ which additionally satisfies $A_s \subseteq \text{succ}_p(s)$ for all $s \in p$ above the stem. Let $D'_s$ be the Fréchet filter on $A_s$. Let $p' \in \text{L}_{D'}$ be the tree with the same stem as $p$ which satisfies $\text{succ}_{p'}(s) = A_s$ for all $s \in p'$ above the stem.

By Lemma 1.5 we know that $\text{L}_{D'M}$ is an $M$-complete subforcing of $\text{L}_{D'}$ (in $M'$ as well as in $V$). We write $G^M$ for the induced filter on $\text{L}_{D'M}$.

We now work in $V$. Note that below the condition $p'$, the forcing $\text{L}_{D'}$ is just Laver forcing $\text{L}$, and that $p' \leq \text{L} p$. Using Lemma 1.29 we can find a condition $q \leq p'$ (in Laver forcing $\text{L}$) such that:

- (1.45) $q$ is $M'$-generic.
- (1.46) $q \Vdash_{\text{L}} r$ is random over $M'[G_L]$ (hence also over $M[G^M]$).
- (1.47) Moreover, $q \Vdash_{\text{L}} Z \sqsubseteq_0 r$.

Enumerate all continuous $\text{L}_{D'M}$-names of codes for null sets from $M$ as $Z_{g_1}, Z_{g_2}, \ldots$. Applying Corollary 1.42 yields a condition $q' \leq q$ such that for all filter systems $E$ satisfying $q' \in \text{L}_{E}$, we have $q' \Vdash_{\text{L}_E} Z_{g_i} \sqsubseteq r$ for all $i$. Corollary 1.40 and Lemma 1.43 now imply:

- (1.48) For every filter system $E$ satisfying $q' \in \text{L}_{E}$, $q'$ forces in $\text{L}_{E}$ that $r$ is random over $M[G^M]$ and that $Z \sqsubseteq_0 r$.

By thinning out $q'$ we may assume that

- (1.49) For each $\nu \in \omega^\omega \cap M$ there is $k$ such that $\nu | k \notin q'$.
We have now described a construction of \( q' = q'(\bar{p}, Z, Z^*) \).

Let \((\bar{p}^n, Z^n, Z^{*n})\) enumerate all triples \((\bar{p}, Z, Z^*) \in M\) where \(\bar{p}\) interprets \(Z\) as \(Z^*\) (and consists of conditions with strictly increasing stems). For each \(n\) write \(\nu^n\) for \(\bigcup_k \text{stem}(p^k_n)\), the branch determined by the stems of the sequence \(\bar{p}^n\). We now define by induction a sequence \(q^n\) of conditions:

- \(q^n = q'(p^0, Z^0, Z^{*0})\).
- Given \(q^{n-1}\) and \((\bar{p}^n, Z^n, Z^{*n})\), we find \(k_0\) such that \(\nu^n | k_0 \not\in q^0 \cup \cdots \cup q^{n-1}\) (using \((1.49)\)). Let \(k_1\) be such that \(\text{stem}(p^k_{k_1})\) has length \(> k_0\). We replace \(\bar{p}^n\) by \(\bar{p}' := (p^k_{k_1})_{k \geq k_1}\). (Obviously, \(\bar{p}'\) still interprets \(Z^n\) as \(Z^{*n}\).) Now let \(q^n := q'(\bar{p}', Z^n, Z^{*n})\).

Note that the stem of \(q^n\) is at least as long as the stem of \(p^k_{k_1}\) and is therefore not in \(q^0 \cup \cdots \cup q^{n-1}\), so \(\text{stem}(q')\) and \(\text{stem}(q^n)\) are incompatible for all \(i \neq j\). Therefore we can choose for each \(s\) an ultrafilter \(D_s\) extending \(D^M_s\) such that \(\text{stem}(q') \subseteq s\) implies \(\text{succ}_{q'}(s) \in D_s\).

Note that all \(q'\) are in \(L_D\). Therefore, we can use \((1.48)\). Also, \(q' \leq p^0\). \(\square\)

Below, in Lemma \((3.33)\) we will prove a preservation theorem using the following “local” variant of “random preservation”:

**Definition 1.50.** Fix a countable model \(M\), a real \(r \in 2^\omega\) and a forcing notion \(Q^M \in M\). Let \(Q^M\) be an \(M\)-complete subforcing of \(Q\). We say that “\(Q\) locally preserves randomness of \(r\) over \(M\)” if there is in \(M\) a sequence \((D^Q_n)_{n \in \omega}\) of open dense subsets of \(Q^M\) such that the following holds:

**Assume that**

- \(M\) thinks that \(\bar{p} := (p^n)_{n \in \omega}\) interprets \((Z_1, \ldots, Z_m)\) as \((Z^*_1, \ldots, Z^*_m)\) (so each \(Z_i\) is a \(Q^M\)-name of a code for a null set and each \(Z^*_i\) is a code for a null set, both in \(M\));
- moreover, each \(p^n\) is in \(D^Q_n\) (we call such a sequence \((p^n)_{n \in \omega}\), or the according interpretation “\(Q\)-quick”);
- \(r\) is random over \(M\);
- \(Z^*_i \subseteq r\) for \(i = 1, \ldots, m\).

**Then there is a \(q \leq Q\) \(p^0\) forcing that**

- \(r\) is random over \(M[G^M]\);
- \(Z_i \subseteq r\) for \(i = 1, \ldots, m\).

Note that this is trivially satisfied if \(r\) is not random over \(M\).

For a variant of this definition, see Section \((6)\)

Setting \(D^Q_n\) to be the set of conditions with stem of length at least \(n\), Lemma \((1.30)\) gives us:

**Corollary 1.51.** If \(Q^M\) is an ultralaver forcing in \(M\) and \(r\) a real, then there is an ultralaver forcing \(Q\) over \(M\) locally preserving randomness of \(r\) over \(M\).

2. **Janus Forcing**

In this section, we define a family of forcing notions that has two faces (hence the name “Janus forcing”): Elements of this family may be countable (and therefore equivalent to Cohen), and they may also be essentially random.

\[Q\] over \(Q^M\)\] just means that \(Q^M\) is an \(M\)-complete subforcing of \(Q\).
In the rest of the paper, we will use the following properties of Janus forcing notions $\mathcal{J}$. (We will use only these properties, so readers who are willing to take these properties for granted could skip to Section 3.) Throughout the whole paper we fix a function $B^* : \omega \to \omega$ given by Corollary 2.2. The Janus forcings will depend on a real parameter $\vec{\ell}^* = (\ell^*_m)_{m \in \omega} \in \omega^\omega$, which grows fast with respect to $B^*$. (In our application, $\vec{\ell}^*$ will be given by a subsequence of an ultralaver real.)

The sequence $\vec{\ell}^*$ and the function $B^*$ together define a notion of a “thin set” (see Definition 1.22).

(1) There is a canonical $\mathcal{J}$-name for a (code for a) null set $\tilde{Z}_\nabla$. Whenever $X \subseteq 2^\omega$ is not thin and $\mathcal{J}$ is countable, then $\mathcal{J}$ forces that $X$ is not strongly meager, witnessed by $\text{nullset}(\tilde{Z}_\nabla)$ (the set we get when we evaluate the code $\tilde{Z}_\nabla$). Moreover, for any $\mathcal{J}$-name $Q$ of a $\sigma$-centered forcing, $\mathcal{J} * Q$ also forces that $X$ is not strongly meager, again witnessed by $\text{nullset}(\tilde{Z}_\nabla)$. (This is Lemma 2.9; “thin” is defined in Definition 1.22.)

(2) Let $M$ be a countable transitive model and $\mathcal{J}^M$ a Janus forcing in $M$. Then $\mathcal{J}^M$ is a Janus forcing in $V$ as well (and of course countable in $V$). (Also note that trivially the forcing $\mathcal{J}^M$ is an $M$-complete subforcing of itself.) (This is Fact 2.8.)

(3) Whenever $M$ is a countable transitive model and $\mathcal{J}^M$ is a Janus forcing in $M$, then there is a Janus forcing $\mathcal{J}$ such that

- $\mathcal{J}^M$ is an $M$-complete subforcing of $\mathcal{J}$.
- $\mathcal{J}$ is (in $V$) equivalent to random forcing (actually we just need that $\mathcal{J}$ preserves Lebesgue positivity in a strong and iterable way). (This is Lemma 2.16 and Lemma 2.20.)

(4) Moreover, the name $Z_\nabla$ referred to in (1) is so “canonical” that it evaluates to the same code in the $\mathcal{J}$-generic extension over $V$ as in the $\mathcal{J}^M$-generic extension over $M$. (This is Fact 2.7.)

2.A. Definition of Janus forcing. A Janus forcing $\mathcal{J}$ will consist of

- A countable “core” (or backbone) $\nabla$ which is defined in a combinatorial way from a parameter $\vec{\ell}^*$. (In our application, we will use a Janus forcing immediately after an ultralaver forcing, and $\vec{\ell}^*$ will be a subsequence of the ultralaver real.) This core is of course equivalent to Cohen forcing.
- Some additional “stuffing” $\mathcal{J} \setminus \nabla$ (countable or uncountable). We allow great freedom for this; we just require that the core $\nabla$ be a “sufficiently” complete subforcing (in a specific combinatorial sense; see Definition 2.5(3)).
We will use the following combinatorial theorem from \cite{BS10}:

**Lemma 2.1** (\cite{BS10} Theorem 8\textsuperscript{21}). For every \(\varepsilon, \delta > 0\) there exists \(N_{\varepsilon, \delta} \in \omega\) such that for all sufficiently large finite sets \(I \subseteq \omega\) there is a family \(A_I\) with \(|A_I| \geq 2\) consisting of sets \(A \subseteq 2^I\) with \(|A| \geq 2^{|I|}/2\) such that if \(X \subseteq 2^I\), \(|X| \geq N_{\varepsilon, \delta}\), then

\[
\left|\left\{ A \in A_I : X + A = 2^I \right\}\right| \geq 1 - \delta.
\]

(Recall that \(X + A := \{ x + a : x \in X, a \in A \}\).)

Rephrasing and specializing to \(\delta = \frac{1}{4}\) and \(\varepsilon = \frac{1}{2}\), we get:

**Corollary 2.2.** For every \(i \in \omega\) there exists \(B^*(i)\) such that for all finite sets \(I\) with \(|I| \geq B^*(i)\) there is a family \(A_I\) with \(|A_I| \geq 2\) satisfying the following:

- \(A_I\) consists of sets \(A \subseteq 2^I\) with \(|A| \geq 2^{|I|}/2\).
- For every \(X \subseteq 2^I\) satisfying \(|X| \geq B^*(i)\), the set \(\{ A \in A_I : X + A = 2^I \}\) has at least \(\frac{3}{4}|A_I|\) elements.

**Assumption 2.3.** We fix a sufficiently fast increasing sequence \(\tilde{\ell}^* = (\ell^*_i)_{i \in \omega}\) of natural numbers. More precisely, the sequence \(\tilde{\ell}^*\) will be a subsequence of an ultralaver real \(\tilde{\ell}\), defined as in Lemma 1.23 using the function \(B^*\) from Corollary 2.2. Note that in this case \(\ell^*_i + 1 - \ell^*_i \geq B^*(i)\), so we can fix for each \(i\) a family \(A_i \subseteq \mathcal{P}(2^{L_i})\) on the interval \(L_i := [\ell^*_i, \ell^*_{i+1})\) according to Corollary 2.2.

**Definition 2.4.** First we define the “core” \(\nabla = \nabla_{\tilde{\ell}}\) of our forcing:

\[
\nabla = \bigcup_{i \in \omega} \prod_{j < i} A_j.
\]

In other words, \(\sigma \in \nabla\) iff \(\sigma = (A_0, \ldots, A_{i-1})\) for some \(i \in \omega\), \(A_0 \in A_0, \ldots, A_{i-1} \in A_{i-1}\). We will denote the number \(i\) by \(\text{height}(\sigma)\).

The forcing notion \(\nabla\) is ordered by reverse inclusion (i.e., end extension): \(\tau \leq \sigma\) if \(\tau \supseteq \sigma\).

**Definition 2.5.** Let \(\tilde{\ell}^* = (\ell^*_i)_{i \in \omega}\) be as in the assumption above. We say that \(\tilde{J}\) is a Janus forcing based on \(\tilde{\ell}^*\) if:

1. \((\nabla, \supseteq)\) is an incompatibility-preserving subforcing of \(\tilde{J}\).
2. For each \(i \in \omega\) the set \(\{ \sigma \in \nabla : \text{height}(\sigma) = i\}\) is predense in \(\tilde{J}\). So in particular, \(\tilde{J}\) adds a branch through \(\nabla\). The union of this branch is called \(C^\nabla = (C_0^\nabla, C_1^\nabla, C_2^\nabla, \ldots)\), where \(C_i^\nabla \subseteq 2^{L_i}\) with \(C_i^\nabla \in A_i\).
3. “Fatness” \textsuperscript{22} For all \(p \in \tilde{J}\) and all real numbers \(\varepsilon > 0\) there are arbitrarily large \(i \in \omega\) such that there is a core condition \(\sigma = (A_0, \ldots, A_{i-1}) \in \nabla\) (of length \(i\)) with

\[
\left| \left\{ A \in A_i : \sigma \upharpoonright A \| \upharpoonright p \right\} \right| \geq 1 - \varepsilon.
\]

\textsuperscript{21}The theorem in \cite{BS10} actually says “for a sufficiently large \(I\)”, but the proof shows that this should be read as “for all sufficiently large \(I\)”. Also, the quoted theorem only claims that \(A_I\) will be non-empty, but for \(\varepsilon \leq \frac{1}{2}\) and \(|I| > N_{\varepsilon, \delta}\) it is easy to see that \(A_I\) cannot be a singleton \(\{ A \}\): The set \(X := 2^I \setminus A\) has size \(\geq 2|I| - 1 \geq N_{\varepsilon, \delta}\) but satisfies \(X + A \neq 2^I\), as the constant sequence \(0\) is not in \(X + A\). \textsuperscript{22}This is the crucial combinatorial property of Janus forcing. Actually, \cite{BS10} implies \cite{2}.
(Recall that \( p \parallel q \) means that \( p \) and \( q \) are compatible in \( J \).)

(4) \( J \) is ccc.

(5) \( J \) is separative.

(6) (To simplify some technicalities:) \( J \subseteq H(\aleph_1) \).

We now define \( Z_\nabla \), which will be a canonical \( J \)-name of (a code for) a null set. We will use the sequence \( \tilde{C}_\nabla \) added by \( J \) (see Definition 2.5(2)).

**Definition 2.6.** Each \( \tilde{C}_\nabla i \) defines a clopen set \( \tilde{Z}_\nabla i = \{ x \in 2^{\omega} : x|L_i \in \tilde{C}_\nabla i \} \) of measure at most \( \frac{1}{2^i} \). The sequence \( \tilde{Z}_\nabla = (\tilde{Z}_\nabla 0, \tilde{Z}_\nabla 1, \tilde{Z}_\nabla 2, \ldots) \) is (a name for) a code for the null set

\[
\text{nullset}(\tilde{Z}_\nabla) = \bigcap_{n<\omega} \bigcup_{i \geq n} \tilde{Z}_\nabla i.
\]

Since \( C_\nabla \) is defined “canonically” (see in particular Definition 2.5(1), (2)) and \( \tilde{Z}_\nabla \) is constructed in an absolute way from \( \tilde{C}_\nabla \), we get:

**Fact 2.7.** If \( J \) is a Janus forcing, \( M \) a countable model and \( J^M \) a Janus forcing in \( M \) which is an \( M \)-complete subset of \( J \), if \( H \) is \( J \)-generic over \( V \) and \( H^M \) the induced \( J^M \)-generic filter over \( M \), then \( C_\nabla \) evaluates to the same real in \( M[H^M] \) as in \( V[H] \), and therefore \( \tilde{Z}_\nabla \) evaluates to the same code (but of course not to the same set of reals).

For later reference, we record the following trivial fact:

**Fact 2.8.** Being a Janus forcing is absolute. In particular, if \( V \subseteq W \) are set theoretical universes and \( J \) is a Janus forcing in \( V \), then \( J \) is a Janus forcing in \( W \). In particular, if \( M \) is a countable model in \( V \) and \( J \in M \) a Janus forcing in \( M \), then \( J \) is also a Janus forcing in \( V \).

Let \( (M^n)_{n \in \omega} \) be an increasing sequence of countable models, and let \( J^n \in M^n \) be Janus forcings. Assume that \( J^n \) is \( M^n \)-complete in \( J^{n+1} \). Then \( \bigcap_n J^n \) is a Janus forcing and an \( M^n \)-complete extension of \( J^n \) for all \( n \).

2.B. Janus and strongly meager. Carlson [Car93] showed that Cohen reals make every uncountable set \( X \) of the ground model not strongly meager in the extension (and that not being strongly meager is preserved in a subsequent forcing with precaliber \( \aleph_1 \)). We show that a *countable* Janus forcing \( J \) does the same (for a subsequent forcing that is even \( \sigma \)-centered, not just precaliber \( \aleph_1 \)). This sounds trivial, since any (non-trivial) countable forcing is equivalent to Cohen forcing anyway. However, we show (and will later use) that the canonical null set \( Z_\nabla \) defined above witnesses that \( X \) is not strongly meager (and not just some null set that we get out of the isomorphism between \( J \) and Cohen forcing). The point is that while \( \nabla \) is not a complete subforcing of \( J \), condition 3 of Definition 2.5 guarantees that Carlson’s argument still works if we assume that \( X \) is non-thin (not just uncountable). This is enough for us, since by Corollary 1.24 ultralaver forcing makes any uncountable set non-thin.

Recall that we fixed the increasing sequence \( \ell^* = (\ell^*_i)_{i \in \omega} \) and \( B^* \). In the following, whenever we say “(very) thin” we mean “(very) thin with respect to \( \ell^* \) and \( B^* \)” (see Definition 1.22).
Lemma 2.9. If $X$ is not thin, $\mathcal{J}$ is a countable Janus forcing based on $\tilde{c}$, and $R$ is a $\mathcal{J}$-name for a $\sigma$-centered forcing notion, then $\mathcal{J} \ast R$ forces that $X$ is not strongly meager, witnessed by the null set $Z_\mathcal{V}$.

Proof. Let $\tilde{c}$ be a $\mathcal{J}$-name for a function $\tilde{c}: R \to \omega$ witnessing that $R$ is $\sigma$-centered.

Recall that “$Z_\mathcal{V}$ witnesses that $X$ is not strongly meager” means that $X + Z_\mathcal{V} = 2^\omega$. Assume towards a contradiction that $(p, r) \in \mathcal{J} \ast R$ forces that $X + Z_\mathcal{V} \neq 2^\omega$.

Then we can fix a $(\mathcal{J} \ast R)$-name $\xi$ such that $(p, r) \Vdash \xi \notin X + Z_\mathcal{V}$, i.e., $(p, r) \Vdash (\forall x \in X) \xi \notin x + Z_\mathcal{V}$. By definition of $Z_\mathcal{V}$, we get

$$(p, r) \Vdash (\forall x \in X) (\exists n \in \omega) (\forall i \geq n) \xi \upharpoonright L_i \notin x \upharpoonright L_i + C_i^\mathcal{V}.$$ 

For each $x \in X$ we can find $(p_x, r_x) \leq (p, r)$ and natural numbers $n_x \in \omega$ such that $p_x$ forces that $\tilde{c}(r_x) = m_x$ and

$$(p_x, r_x) \Vdash (\forall i \geq n_x) \xi \upharpoonright L_i \notin x \upharpoonright L_i + C_i^\mathcal{V}.$$ 

Since $X^*$ is not very thin, there is some $i_0 \in \omega$ such that for all $i \geq i_0$,

$$(2.10) \quad (p^*, r_x) \Vdash (\forall i \geq n_x) \xi \upharpoonright L_i \notin x \upharpoonright L_i + C_i^\mathcal{V}. $$

So $X = \bigcup_{p \in \mathcal{J}, m \in \omega, n \in \omega} X_{p, m, n}$, where $X_{p, m, n}$ is the set of all $x$ with $p_x = p$, $m_x = m$, $n_x = n$. (Note that $\mathcal{J}$ is countable, so the union is countable.) As $X$ is not thin, there is some $p^*, m^*, n^*$ such that $X^* := X_{p^*, m^*, n^*}$ is not very thin. So we get for all $x \in X^*$:

$$(2.11) \quad (p_x, r_x) \Vdash (\forall i \geq n_x) \xi \upharpoonright L_i \notin x \upharpoonright L_i + C_i^\mathcal{V}.$$ 

Due to the fact that $\mathcal{J}$ is a Janus forcing (see Definition 2.5(3)), there are arbitrarily large $i \in \omega$ such that there is a core condition $\sigma = (A_0, \ldots, A_{i-1}) \in \mathcal{V}$ with

$$|\{A \in A_i : \sigma \upharpoonright A \parallel_{\mathcal{J}} p^*\}| \geq \frac{2}{3}.$$ 

(2.12)

Fix such an $i$ larger than both $i_0$ and $n^*$, and fix a condition $\sigma$ satisfying (2.12).

We now consider the following two subsets of $A_i$:

$$(2.13) \quad \{A \in A_i : \sigma \upharpoonright A \parallel_{\mathcal{J}} p^*\} \quad \text{and} \quad \{A \in A_i : X^* \upharpoonright L_i + A = 2^{L_i}\}.$$ 

By (2.12), the relative measure (in $A_i$) of the left one is at least $\frac{2}{3}$. Due to (2.11) and the definition of $A_i$ according to Corollary 2.2, the relative measure of the right one is at least $\frac{3}{4}$, so the two sets in (2.13) are not disjoint and we can pick an $A$ belonging to both.

Clearly, $\sigma \upharpoonright A$ forces (in $\mathcal{J}$) that $C_i^\mathcal{V}$ is equal to $A$. Fix $q \in \mathcal{J}$ witnessing $\sigma \upharpoonright A \parallel_{\mathcal{J}} p^*$. Then

$$(2.14) \quad q \Vdash_{\mathcal{J}} X^* \upharpoonright L_i + C_i^\mathcal{V} = X^* \upharpoonright L_i + A = 2^{L_i}.$$ 

Since $p^*$ forces that for each $x \in X^*$ the color $\tilde{c}(r_x) = m^*$, we can find an $r^*$ which is (forced by $q \leq p^*$ to be) a lower bound of the finite set $\{r_x : x \in X^{**}\}$, where $X^{**} \subseteq X^*$ is any finite set with $X^{**} \upharpoonright L_i = X^* \upharpoonright L_i$.

By (2.10),

$$(q, r^*) \Vdash \xi \upharpoonright L_i \notin X^{**} \upharpoonright L_i + C_i^\mathcal{V} = X^* \upharpoonright L_i + C_i^\mathcal{V},$$ 

contradicting (2.14). \hfill \Box

Recall that by Corollary 2.24 every uncountable set $X$ in $V$ will not be thin in the $\mathbb{L}_D$-extension. Hence we get:
Corollary 2.15. Let $X$ be uncountable. If $\mathbb{L}_D$ is any ultralaver forcing adding an ultralaver real $\ell$, if $\tilde{\ell}^*$ is defined from $\ell$ as in Lemma 1.28 and if $\mathbb{J}$ is a countable Janus forcing based on $\tilde{\ell}^*$ and $Q$ is any $\sigma$-centered forcing, then $\mathbb{L}_D \ast \mathbb{J} \ast Q$ forces that $X$ is not strongly meager.

2.C. Janus forcing and preservation of Lebesgue positivity. We show that every Janus forcing in a countable model $M$ can be extended to locally preserve a given random real over $M$. (We showed the same for ultralaver forcing in Section 1.E.)

We start by proving that every countable Janus forcing can be embedded into a Janus forcing which is equivalent to random forcing, preserving the maximality of countably many maximal antichains. (In the following lemma, the letter $M$ is just a label to distinguish $\mathbb{J}^M$ from $\mathbb{J}$ and does not necessarily refer to a model.)

Lemma 2.16. Let $\mathbb{J}^M$ be a countable Janus forcing (based on $\tilde{\ell}^*$) and let $\{D_k : k \in \omega\}$ be a countable family of open dense subsets of $\mathbb{J}^M$. Then there is a Janus forcing $\mathbb{J}$ (based on the same $\tilde{\ell}^*$) such that

- $\mathbb{J}^M$ is an incompatibility-preserving subforcing of $\mathbb{J}$.
- Each $D_k$ is still predense in $\mathbb{J}$.
- $\mathbb{J}$ is forcing equivalent to random forcing.

Proof. Without loss of generality assume $D_0 = \mathbb{J}^M$. Recall that $\nabla = \nabla^{\mathbb{J}^M}$ was defined in Definition 2.3. Note that for each $j$ the set $\{\sigma \in \nabla : \text{height}(\sigma) = j\}$ is predense in $\mathbb{J}^M$, so the set

$$E_j := \{p \in \mathbb{J}^M : \exists \sigma \in \nabla : \text{height}(\sigma) = j, \ p \leq \sigma\}$$

is dense open in $\mathbb{J}^M$. Hence without loss of generality each $E_j$ appears in our list of $D_k$’s.

Let $\{r^n : n \in \omega\}$ be an enumeration of $\mathbb{J}^M$.

We now fix $n$ for a while (up to 2.13). We will construct a finitely splitting tree $S^n \subseteq \omega^{<\omega}$ and a family $(\sigma^n_s, p^n_s, \tau^n_s)_{s \in S^n}$ satisfying the following (suppressing the superscript $n$):

(a) $\sigma_s \in \nabla$, $\sigma_\emptyset = \emptyset$, $s \subseteq t$ implies $\sigma_s \subseteq \sigma_t$, and $s \perp_{\nabla} t$ implies $\sigma_s \perp_{\nabla} \sigma_t$.

(These in particular the set $\{\sigma_t : t \in \text{succ}_{S^n}(s)\}$ is a (finite) antichain above $\sigma_s$ in $\nabla$.)

(b) $p_s \in \mathbb{J}^M$, $p_\emptyset = r^n$; if $s \subseteq t$, then $p_t \leq_{\mathbb{J}^M} p_s$ (hence $p_t \leq r^n$). $s \perp_{\nabla} t$ implies $p_s \perp_{\mathbb{J}^M} p_t$.

(c) $p_s \leq_{\mathbb{J}^M} \sigma_s$.

(d) $\sigma_s \subseteq \tau^n_s \in \nabla$, and $\{\sigma_t : t \in \text{succ}_{S^n}(s)\}$ is the set of all $\tau \in \text{succ}_{\nabla}(\tau^n_s)$ which are compatible with $p_s$.

(e) The set $\{\sigma_t : t \in \text{succ}_{S^n}(s)\}$ is a subset of $\text{succ}_\nabla(\tau^n_s)$ of relative size at least $1 - \frac{1}{\text{lh}(s)+1}$.

(f) Each $s \in S^n$ has at least 2 successors in $S^n$.

(g) If $k = \text{lh}(s)$, then $p_s \in D_k$ (and therefore also in all $D_l$ for $l < k$).

Set $\sigma_\emptyset = \emptyset$ and $p_\emptyset = r^n$. Given $s, \sigma_s$ and $p_s$, we construct $\text{succ}_{S^n}(s)$ and $(\sigma_t, p_t)_{t \in \text{succ}_{S^n}(s)}$. We apply Definition 2.3 (fatness) to $p_s$ with $\varepsilon = \frac{1}{\text{lh}(s)+1}$. So we get some $\tau^n_s \in \nabla$ of height larger than the height of $\sigma_s$ such that the set $B$ of elements of $\text{succ}_\nabla(\tau^n_s)$ which are compatible with $p_s$ has relative size at least $1 - \varepsilon$. Since $p_s \leq_{\mathbb{J}^M} \sigma_s$ we get that $\tau^n_s$ is compatible with (and therefore stronger than)
σ, Enumerate B as \{τ₀, \ldots, τ_{l-1}\}. Set \text{succ}_{S^n}(s) = \{s^−i : i < l\} and σ_{s^−i} = τ_i. For t ∈ \text{succ}_{S^n}(s), choose \text{p}_t \in \mathbb{J}^M stronger than both σ_t and \text{p}_s (which is obviously possible since σ_t and \text{p}_s are compatible), and moreover \text{p}_t \in D_{\text{lh}(t)}. This concludes the construction of the family \((σ^n_s, p^n_s, τ^n_s)_{s \in S^n}\).

So \((S^n, \subseteq)\) is a finitely splitting non-empty tree of height \(ω\) with no maximal nodes and no isolated branches. \([S^n]\) is the (compact) set of branches of \(S^n\). The closed subsets of \([S^n]\) are exactly the sets of the form \([T]\), where \(T \subseteq S^n\) is a subtree of \(S^n\) with no maximal nodes. \([S^n]\) carries a natural (“uniform”) probability measure \(μ_n\), which is characterized by

\[
μ_n(\{S^n[^{[t]}]\}) = \frac{1}{|\text{succ}_{S^n}(s)|} \cdot μ_n(\{S^n[^{[s]}]\})
\]

for all \(s \in S^n\) and all \(t \in \text{succ}_{S^n}(s)\). (We just write \(μ_n(T)\) instead of \(μ_n(\{T\})\) to increase readability.)

We call \(T \subseteq S^n\) positive if \(μ_n(T) > 0\), and we call \(T\) pruned if \(μ_n(T[^{[s]}]) > 0\) for all \(s \in T\). (Clearly every positive tree \(T\) contains a pruned tree \(T'\) of the same measure, which can be obtained from \(T\) by removing all nodes \(s\) with \(μ_n(T[^{[s]}]) = 0\).)

Let \(T \subseteq S^n\) be a positive pruned tree and \(ε > 0\). Then on all but finitely many levels \(k\) there is an \(s \in T\) such that

\[
\text{succ}_{T}(s) \subseteq \text{succ}_{S^n}(s) \text{ has relative size } \geq 1 - ε.
\]

(2.18) This follows from Lebesgue’s density theorem or can easily be seen directly: Set \(C_m = \bigcup_{t \in T, \text{lh}(t)=m} (S^n[^{[t]}])\). Then \(C_m\) is a decreasing sequence of closed sets, each containing \([T]\). If the claim fails, then \(μ_n(C_{m+1}) ≤ μ_n(C_m) · (1 - ε)\) infinitely often; so \(μ_n(T) ≤ μ_n(\bigcap_m C_m) = 0\).

It is well known that the set of positive, pruned subtrees of \(S^n\), ordered by inclusion, is forcing equivalent to random forcing (which can be defined as the set of positive, pruned subtrees of \(2^{<ω}\)).

We have now constructed \(S^n\) for all \(n\). Define

\[
\mathbb{J} = \mathbb{J}^M \cup \bigcup_n \{ (n, T) : T \subseteq S^n \text{ is a positive pruned tree}\}
\]

with the following partial order:

- The order on \(\mathbb{J}\) extends the order on \(\mathbb{J}^M\).
- \((n', T') \leq (n, T)\) if \(n = n'\) and \(T' \subseteq T\).
- For \(p \in \mathbb{J}^M\): \((n, T) \leq p\) if there is a \(k\) such that \(p^n_k \leq p\) for all \(t \in T\) of length \(k\). (Note that this will then be true for all larger \(k\) as well.)
- \(p \leq (n, T)\) never holds (for \(p \in \mathbb{J}^M\)).

The lemma now easily follows from the following properties:

1. The order on \(\mathbb{J}\) is transitive.
2. \(\mathbb{J}^M\) is an incompatibility-preserving subforcing of \(\mathbb{J}\).
   In particular, \(\mathbb{J}\) satisfies item (1) of Definition 2.5 of Janus forcing.
3. For all \(k\), the set \(\{(n, T[^{[t]}]) : t \in T, \text{lh}(t) = k\}\) is a (finite) predense antichain below \((n, T)\).
4. \((n, T[^{[t]}])\) is stronger than \(p^n_t\) for each \(t \in T\) (witnessed, e.g., by \(k = \text{lh}(t)\)).
   Of course, \((n, T[^{[t]}])\) is stronger than \((n, T)\) as well.
5. Since \(p^n_t \in D_k\) for \(k = \text{lh}(t)\), this implies that each \(D_k\) is predense below each \((n, S^n)\) and therefore in \(\mathbb{J}\).

Also, since each set \(E_j\) appeared in our list of open dense subsets (see
(2.17), the set \( \{ \sigma \in \nabla : \text{height}(\sigma) = j \} \) is still predense in \( J \), i.e., item (2) of Definition 2.5 of Janus forcing is satisfied.

(6) The condition \( (n, S^n) \) is stronger than \( r^n \), so \( \{(n, S^n) : n \in \omega \} \) is predense in \( J \) and \( J \setminus J^M \) is dense in \( J \).

Below each \( (n, S^n) \), the forcing \( \mathbb{J} \) is isomorphic to random forcing. Therefore, \( \mathbb{J} \) itself is forcing equivalent to random forcing. (In fact, the complete Boolean algebra generated by \( \mathbb{J} \) is isomorphic to the standard random algebra, Borel sets modulo null sets.) This proves in particular that \( \mathbb{J} \) is ccc, i.e., satisfies the property required in Definition 2.5(1).

(7) It is easy (but not even necessary) to check that \( \mathbb{J} \) is separative, i.e., the property required in Definition 2.5(5). In any case, we could replace \( \leq J \) by \( \leq J^* \), thus making \( \mathbb{J} \) separative without changing \( \leq J_M \), since \( \mathbb{J}^M \) was already separative.

(8) The property required in Definition 2.5(6), i.e., \( \mathbb{J} \in H(\aleph_1) \), is obvious.

(9) The remaining item of the definition of Janus forcing, the fatness required in Definition 2.5(3), is satisfied.

I.e., given \( (n, T) \in \mathbb{J} \) and \( \varepsilon > 0 \) there is an arbitrarily high \( \tau^* \in \nabla \) such that the relative size of the set \( \{ \tau \in \text{succ}_\nabla(\tau^*) : \tau \parallel (n, T) \} \) is at least \( 1 - \varepsilon \).

(We will show \( \geq (1 - \varepsilon)^2 \) instead, to simplify the notation.)

We show (9): Given \( (n, T) \in \mathbb{J} \) and \( \varepsilon > 0 \), we use (2.18) to get an arbitrarily high \( s \in T \) such that \( \text{succ}_\nabla(s) \) is of relative size \( \geq 1 - \varepsilon \) in \( \text{succ}_{\nabla^n}(s) \). We may choose \( s \) of length \( > \frac{1}{2} \). We claim that \( \tau^*_s \) is as required:

- Let \( B := \{ \sigma_t : t \in \text{succ}_{\nabla^n}(s) \} \). Note that \( B = \{ \tau \in \text{succ}_\nabla(\tau^*_s) : \tau \parallel p^* \} \).
  - \( B \) has relative size \( \geq 1 - \frac{1}{\text{lh}(s)} \geq 1 - \varepsilon \) in \( \text{succ}_\nabla(\tau^*_s) \) (according to property (c) of \( S^n \)).
  - \( C := \{ \sigma_t : t \in \text{succ}_\nabla(s) \} \) is a subset of \( B \) of relative size \( \geq 1 - \varepsilon \) according to our choice of \( s \).
  - So \( C \) is of relative size \( (1 - \varepsilon)^2 \) in \( \text{succ}_\nabla(\tau^*_s) \).
  - Each \( \sigma_t \in C \) is compatible with \( (n, T) \), as \( (n, T[i]) \leq p_i \leq \sigma_t \) (see (4)).

So, in particular, if \( \mathbb{J}^M \) is a Janus forcing in a countable model \( M \), then we can extend it to a Janus forcing \( \mathbb{J} \) which is in fact random forcing. Since random forcing strongly preserves randoms over countable models (see Lemma 1.29), it is not surprising that we get local preservation of randoms for Janus forcing, i.e., the analoga of Lemma 1.30 and Corollary 1.51. (Still, some additional argument is needed, since the fact that \( \mathbb{J} \) (which is now random forcing) “strongly preserves randoms” just means that a random real \( r \) over \( M \) is preserved with respect to random forcing in \( M \), not with respect to \( \mathbb{J}^M \).)

Lemma 2.20. If \( \mathbb{J}^M \) is a Janus forcing in a countable model \( M \) and \( r \) a random real over \( M \), then there is a Janus forcing \( \mathbb{J} \) such that \( \mathbb{J}^M \) is an \( M \)-complete subforcing of \( \mathbb{J} \) and the following holds:

If

- \( p \in \mathbb{J}^M \),
- in \( M \), \( \tilde{Z} = (Z_1, \ldots, Z_m) \) is a sequence of \( \mathbb{J}^M \)-names for codes for null sets and \( Z_1^*, \ldots, Z_m^* \) are interpretations under \( p \), witnessed by a sequence \( (p_n)_{n \in \omega} \),
- \( Z_i^* \subseteq k_i, r \) for \( i = 1, \ldots, m \),
then there is a \( q \leq p \) in \( \mathbb{J} \) forcing that
• \( r \) is random over \( M[H^M] \),
• \( Z_i \sqsubset_{k_i} r \) for \( i = 1, \ldots, m \).

**Remark 2.21.** In the version for ultralaver forcings, i.e., Lemma [1.30], we had to assume that the stems of the witnessing sequence are strictly increasing. In the Janus version, we do not have any requirement of that kind.

**Proof.** Let \( \mathcal{D} \) be the set of dense subsets of \( J^M \) in \( M \). According to Lemma [1.24], we can first find some countable \( M' \) such that \( r \) is still random over \( M' \) and such that in \( M' \) both \( J^M \) and \( \mathcal{D} \) are countable. According to Fact [2.8], \( J^M \) is a (countable) Janus forcing in \( M' \), so we can apply Lemma [2.16] to the set \( \mathcal{D} \) to construct a Janus forcing \( J^{M'} \) which is equivalent to random forcing such that (from the point of \( V \)) \( J^M \preceq M J^{M'} \). In \( V \), let \( J \) be random forcing. \( J^{M'} \) is an \( M' \)-complete subforcing of \( J \) and therefore \( J^M \preceq M J \). Moreover, as was noted in Lemma [1.29], we even know that random forcing strongly preserves randomness over \( M' \) (see Definition [1.50]). To show that \( J \) is indeed a Janus forcing, we have to check Definition [2.5] (3) (fatness); this follows easily from \( \Pi^1_1 \)-absoluteness (recall that incompatibility of random conditions is Borel).

So assume that (in \( M \)) the sequence \( (p_n)_{n \in \omega} \) of \( J^M \)-conditions interprets \( \bar{Z} \) as \( Z^* \). In \( M' \), \( J^M \)-names can be reinterpreted as \( J^{M'} \)-names, and the \( J^{M'} \)-name \( \bar{Z} \) is interpreted as \( Z^* \) by the same sequence \( (p_n)_{n \in \omega} \). Let \( k_1, \ldots, k_m \) be such that \( Z^*_i \sqsubset_{k_i} r \) for \( i = 1, \ldots, m \). So by strong preservation of randomness, we can in \( V \) find some \( q \leq p_0 \) forcing that \( r \) is random over \( M'(H^{M'}) \) (and therefore also over the subset \( M[H^{M'}] \)) and that \( Z_i \sqsubset_{k_i} r \) (where \( Z_i \) can be evaluated in \( M'(H^{M'}) \) or equivalently in \( M[H^{M'}] \)). \( \square \)

So Janus forcing locally preserves randomness (just as ultralaver forcing does):

**Corollary 2.22.** If \( Q^M \) is a Janus forcing in \( M \) and \( r \) a real, then there is a Janus forcing \( Q \) over \( Q^M \) (which is in fact equivalent to random forcing) locally preserving randomness of \( r \) over \( M \).

**Proof.** In this case, the notion of “quick” interpretations is trivial, i.e., \( D^Q_{k^*} = Q^M \) for all \( k \), and the claim follows from the previous lemma. \( \square \)

3. Almost finite and almost countable support iterations

A main tool to construct the forcing for \( BC+dBC \) will be “partial countable support iterations”, more particularly “almost finite support” and “almost countable support” iterations. A partial countable support iteration is a forcing iteration \( (P, Q)_{\alpha < \omega_2} \) such that for each limit ordinal \( \delta \) the forcing notion \( P_\delta \) is a subset of the countable support limit of \( (P, Q)_{\alpha < \delta} \) which satisfies some natural properties (see Definition [3.6]).

Instead of transitive models, we will use ord-transitive models (which are transitive when ordinals are considered as urelements). Why do we do that? We want to “approximate” the generic iteration \( P \) of length \( \omega_2 \) with countable models; this can be done more naturally with ord-transitive models (since obviously countable transitive models only see countable ordinals). We call such an ord-transitive model a

\[ \text{BOREL CONJECTURE AND DUAL BOREL CONJECTURE 271} \]

\[ 24 \text{More precisely: Densely embed } J^{M'} \text{ into } (\text{Borel/null})^{M'}, \text{ the complete Boolean algebra associated with random forcing in } M', \text{ and let } J := (\text{Borel/null})^V. \text{ Using the embedding, } J^{M'} \text{ can now be viewed as an } M'-\text{complete subset of } J. \]

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
"candidate" (provided it satisfies some nice properties; see Definition 3.1). A basic point is that forcing extensions work naturally with candidates.

In the next few paragraphs (and also in Section 4), \( x = (M^x, \mathcal{P}^x) \) will denote a pair such that \( M^x \) is a candidate and \( \mathcal{P}^x \) is (in \( M^x \)) a partial countable support iteration. Similarly we write, e.g., \( y = (M^y, \mathcal{P}^y) \) or \( x_n = (M^{x_n}, \mathcal{P}^{x_n}) \).

We will need the following results to prove \( \text{BC+dBC} \). (However, as opposed to the case of the ultralaver and Janus section, the reader will probably have to read this section to understand the construction in the next section, and not just the following list of properties.)

Given \( x = (M^x, \mathcal{P}^x) \), we can construct by induction on \( \alpha \) a partial countable support iteration \( \mathcal{P} = (P_\alpha, Q_\alpha)_{\alpha < \omega_2} \) satisfying:

There is a canonical \( M^x \)-complete embedding from \( \mathcal{P}^x \) to \( \mathcal{P} \).

In this construction, we can use at each stage \( \beta \) any desired \( Q_\beta \), as long as \( P_\beta \) forces that \( Q_\beta^0 \) is (evaluated as) an \( M^x[H_\beta]^x \)-complete subforcing of \( Q_\beta \) (where \( H_\beta^x \subseteq P_\beta^x \) is the \( M^x \)-generic filter induced by the generic filter \( H_\beta \subseteq P_\beta \)).

Moreover, we can demand either of the following two additional properties\(^{25}\) of the limit of this iteration \( \mathcal{P} \):

1. If all \( Q_\beta \) are forced to be \( \sigma \)-centered and \( Q_\beta \) is trivial for all \( \beta \not\in M^x \), then \( P_{\omega_2} \) is \( \sigma \)-centered.
2. If \( r \) is random over \( M^x \) and all \( Q_\beta \) locally preserve randomness of \( r \) over \( M^x[H_\beta^x] \) (see Definition 1.50), then also \( P_{\omega_2} \) locally preserves the randomness of \( r \).

Actually, we need the following variant: Assume that we already have \( P_{\alpha_0} \) for some \( \alpha_0 \in M^x \), that \( P_{\alpha_0}^x \) canonically embeds into \( P_{\alpha_0} \), and that the respective assumption on \( Q_\beta \) holds for all \( \beta \geq \alpha_0 \). Then we get that \( P_{\alpha_0} \) forces that the quotient \( P_{\omega_2}/P_{\alpha_0} \) satisfies the respective conclusion.

We also need\(^{25}\)

3. If instead of a single \( x \) we have a sequence \( x_n \) such that each \( P_{\alpha_n}^x \) canonically (and \( M^{x_n} \)-completely) embeds into \( P_{\alpha_n+1}^x \), then we can find a partial countable support iteration \( \mathcal{P} \) into which all \( P_{\alpha_n}^x \) embed canonically (and we can again use any desired \( Q_\beta \), assuming that \( Q_\beta^{x_n} \) is an \( M^{x_n}[H_\beta^{x_n}] \)-complete subforcing of \( Q_\beta \) for all \( n \in \omega \)).

4. (A fact that is easy to prove but awkward to formulate.) If a \( \Delta \)-system argument produces two \( x_1, x_2 \) as in Lemma 4.7(3), then we can find a partial countable support iteration \( \mathcal{P} \) such that \( \mathcal{P}^{x_i} \) canonically (and \( M^{x_i} \)-completely) embeds into \( \mathcal{P} \) for \( i = 1, 2 \).

3.A. Ord-transitive models. We will use "ord-transitive" models, as introduced in [She04] (see also the presentation in [Kel12]). We briefly summarize the basic definitions and properties (restricted to the rather simple case needed in this paper):

Definition 3.1. Fix a suitable finite subset \( \text{ZFC}^* \) of \( \text{ZFC} \) (that is satisfied by \( H(\chi^*) \) for sufficiently large regular \( \chi^* \)).

1. A set \( M \) is called a candidate if
   - \( M \) is countable,

25The \( \sigma \)-centered version is central for the proof of dBC; the random-preserving version for BC.

26This will give \( \sigma \)-closure and \( \aleph_2 \)-cc for the preparatory forcing \( \mathbb{R} \).
(1) The ord-collapse of a countable elementary submodel of $H(\chi^+)$ is a nice candidate.

(2) Unions, intersections, etc. are generally not absolute for candidates. For example, let $x \in M \setminus \text{Ord}$. In $M$ we can construct a set $y$ such that $M \models y = \omega_1 \cup \{x\}$. Then $y$ is not an ordinal and therefore a subset of $M$, and in particular $y$ is countable and $y \neq \omega_1 \cup \{x\}$.

(3) Let $j : M \to M'$ be the transitive collapse of a candidate $M$ and $f : \omega_1 \cap M' \to \text{Ord}$ the inverse (restricted to the ordinals). Obviously $M'$ is a countable transitive model of $\text{ZFC}^+$; moreover, $M$ is characterized by the pair $(M', f)$ (we call such a pair a “labeled transitive model”). Note that $f$ satisfies $f(\alpha + 1) = f(\alpha) + 1$, $f(\alpha) = \alpha$ for $\alpha \in \omega \cup \{\omega\}$. $M \models (\alpha$ is a limit) iff $f(\alpha)$ is a limit. $M \models \text{cf}(\alpha) = \omega$ iff $\text{cf}(f(\alpha)) = \omega$, and in that case $f[\alpha]$ is
cofinal in \( f(\alpha) \). On the other hand, given a transitive countable model \( M' \) of \( \text{ZFC}^* \) and an \( f \) as above, then we can construct a (unique) candidate \( M \) corresponding to \((M', f)\).

(4) All candidates \( M \) with \( M \cap \text{Ord} \subseteq \omega_1 \) are hereditarily countable, so their number is at most \( 2^{\aleph_0} \). Similarly, the cardinality of \( \text{HCON}_\alpha \) is at most continuum whenever \( \alpha < \omega_2 \).

(5) If \( M \) is a candidate and if \( H^M \) is \( P^M \)-generic over \( M \), then \( M[H^M] \) is a candidate as well and an end-extension of \( M \) such that \( M \cap \text{Ord} = M[H^M] \cap \text{Ord} \). If \( M \) is nice and (\( M \) thinks that) \( P^M \) is proper, then \( M[H^M] \) is nice as well.

(6) Forcing extensions commute with the transitive collapse \( j \): If \( M \) corresponds to \((M', f)\), then \( H^M \subseteq P^M \)-generic over \( M \) iff \( H' := j[H^M] \) is \( P' := j(P^M) \)-generic over \( M' \), and in that case \( M[H^M] \) corresponds to \((M'[H'], f)\). In particular, the forcing extension \( M[H^M] \) of \( M \) satisfies the forcing theorem (everything that is forced is true, and everything true is forced).

(7) For elementary submodels, forcing extensions commute with ord-collapses: Let \( N \) be a countable elementary submodel of \( H(\chi^*) \), \( P \in N, k : N \to M \) the ord-collapse (so \( M \) is a candidate), and let \( H \) be \( P \)-generic over \( V \). Then \( H \) is \( P \)-generic over \( N \) iff \( H^M := k[H] \) is \( P^M := k(P) \)-generic over \( M \). In that case the ord-collapse of \( N[H] \) is \( M[H^M] \).

Assume that a nice candidate \( M \) thinks that \((\bar{P}^M, \bar{Q}^M)\) is a forcing iteration of length \( \omega_2^V \) (we will usually write \( \omega_2 \) for the length of the iteration; by this we will always mean \( \omega_2^V \) and not the possibly different \( \omega_2^M \)). In this section, we will construct an iteration \((P, Q)\) in \( V \), also of length \( \omega_2 \), such that each \( P^M_\alpha \) canonically and \( M \)-completely embeds into \( P_\alpha \) for all \( \alpha \in \omega_2 \cap M \). Once we know (by induction) that \( P^M_\alpha \) \( M \)-completely embeds into \( P_\alpha \), we know that a \( P_\alpha \)-generic filter \( H_\alpha \) induces a \( P^M_\alpha \)-generic (over \( M \)) filter which we call \( H^M_\alpha \). Then \( M[H^M_\alpha] \) is a candidate, but nice only if \( P^M_\alpha \) is proper. We will not need that \( M[H^M_\alpha] \) is nice, actually we will only investigate sets of reals (or elements of \( H(\aleph_1) \)) in \( M[H^M_\alpha] \), so it does not make any difference whether we use \( M[H^M_\alpha] \) or its transitive collapse.

Remark 3.3. In the discussion so far we have omitted some details regarding the theory \( \text{ZFC}^* \) (that a candidate has to satisfy). The following “fine print” hopefully absolves us from any liability. (It is entirely irrelevant for the understanding of the paper.)

We have to guarantee that each \( M[H^M_\alpha] \) that we consider satisfies enough of \( \text{ZFC} \) to make our arguments work (for example, the definitions and basic properties of ultralayer and Janus forcings should work). This turns out to be easy, since (as usual) we do not need the full power set axiom for these arguments (just the existence of, say, \( \beth_3 \)). So it is enough that each \( M[H^M_\alpha] \) satisfies some fixed finite subset of \( ZFC - \text{power set} \), which we call \( \text{ZFC}^* \).

Of course, we can also find a larger (still finite) set \( \text{ZFC}^{**} \) that implies: \( \beth_{10} \) exists, and each forcing extension of the universe with a forcing of size \( \leq \beth_4 \) satisfies \( \text{ZFC}^* \). Also, it is provable (in \( \text{ZFC} \)) that each \( H(\chi) \) satisfies \( \text{ZFC}^{**} \) for sufficiently large regular \( \chi \).

We define “candidate” using the weaker theory \( \text{ZFC}^* \), and require that nice candidates satisfy the stronger theory, \( \text{ZFC}^{**} \). This guarantees that all forcing extensions (by small forcings) of nice candidates will be candidates (in particular,
satisfy enough of ZFC such that our arguments about Janus or ultralaver forcings work. Also, every ord-collapse of a countable elementary submodel $N$ of $H(\chi)$ will be a nice candidate.

3.B. Partial countable support iterations. We introduce the notion of a “partial countable support limit”: a subset of the countable support (CS) limit containing the union (i.e., the direct limit) and satisfying some natural requirements.

Let us first describe what we mean by “forcing iteration”. They have to satisfy the following requirements:

- A “topless forcing iteration” $(P_\alpha, Q_\alpha)_{\alpha<\varepsilon}$ is a sequence of forcing notions $P_\alpha$ and $P_\alpha$-names $Q_\alpha$ of quasiorders with a weakest element $1_{Q_\alpha}$. A “topped iteration” additionally has a final limit $P_\varepsilon$. Each $P_\alpha$ is a set of partial functions on $\alpha$ (as, e.g., in [Go93]). More specifically, if $\alpha < \beta \leq \varepsilon$ and $p \in P_\beta$, then $p|\alpha \in P_\alpha$. Also, $p|\beta \Vdash_{P_\beta} p(\beta) \in Q_\beta$ for all $\beta \in \text{dom}(p)$.
- The order on $P_\beta$ will always be the “natural” one: $q \leq p$ iff $q|\alpha$ forces (in $P_\alpha$) that $q^{\text{tot}}(\alpha) \leq p^{\text{tot}}(\alpha)$ for all $\alpha < \beta$, where $r^{\text{tot}}(\alpha) = r(\alpha)$ for all $\alpha \in \text{dom}(r)$ and $1_{Q_\alpha}$ otherwise. $P_{\alpha+1}$ consists of all $p$ with $p|\alpha \in P_\alpha$ and $p|\alpha \Vdash_{P_\alpha} p^{\text{tot}}(\alpha) \in Q_\alpha$, so it is forcing equivalent to $P_\alpha * Q_\alpha$.
- $P_\alpha \subseteq P_\beta$ whenever $\alpha < \beta \leq \varepsilon$. (In particular, the empty condition is an element of each $P_\beta$.)
- For any $p \in P_\varepsilon$ and any $q \in P_\alpha$ ($\alpha < \varepsilon$) with $q \leq p|\alpha$, the partial function $q \wedge p := q \cup p|\alpha, \varepsilon)$ is a condition in $P_\varepsilon$ as well (so, in particular, $p|\alpha$ is a reduction of $p$, hence $P_\alpha$ is a complete subforcing of $P_\varepsilon$; $q \wedge p$ is the weakest condition in $P_\varepsilon$ stronger than both $q$ and $p$).
- Abusing notation, we usually just write $\bar{P}$ for an iteration (be it topless or topped).
- We usually write $H_\beta$ for the generic filter on $P_\beta$ (which induces $P_\alpha$-generic filters called $H_\alpha$ for $\alpha \leq \beta$). For topped iterations we sometimes call the filter on the final limit $H$ instead of $H_\varepsilon$.

We use the following notation for quotients of iterations:

- Let $\alpha < \beta$. In the $P_\alpha$-extension $V[H_\alpha]$, we let $P_\beta/H_\alpha$ be the set of all $p \in P_\beta$ with $p|\alpha \in H_\alpha$ (ordered as in $P_\beta$). We may occasionally write $P_{\beta}/P_\alpha$ for the $P_\alpha$-name of $P_\beta/H_\alpha$.
- Since $P_\alpha$ is a complete subforcing of $P_\beta$, this is a quotient with the usual properties; in particular, $P_\beta$ is equivalent to $P_\alpha * (P_\beta/H_\alpha)$.

Remark 3.4. It is well known that quotients of proper countable support iterations are naturally equivalent to (names of) countable support iterations. In this paper, we can restrict our attention to proper forcings, but we do not really have countable support iterations. It turns out that it is not necessary to investigate whether our quotients can naturally be seen as iterations of any kind, so to avoid the subtle problems involved we will not consider the quotient as an iteration by itself.

Definition 3.5. Let $\bar{P}$ be a (topless) iteration of limit length $\varepsilon$. We define three limits of $\bar{P}$:

- The “direct limit” is the union of the $P_\alpha$ (for $\alpha < \varepsilon$). So this is the smallest possible limit of the iteration.
- The “inverse limit” consists of all partial functions $p$ with domain $\subseteq \varepsilon$ such that $p|\alpha \in P_\alpha$ for all $\alpha < \varepsilon$. This is the largest possible limit of the iteration.
• The “full countable support limit $P^\text{CS}_\varepsilon$” of $\bar{P}$ is the inverse limit if $\text{cf}(\varepsilon) = \omega$
and the direct limit otherwise.

We say that $P_\varepsilon$ is a “partial CS limit” if $P_\varepsilon$ is a subset of the full CS limit and the
sequence $(P_\alpha)_{\alpha \leq \varepsilon}$ is a topped iteration. In particular, this means that $P_\varepsilon$
contains the direct limit and satisfies the following for each $\alpha < \varepsilon$: $P_\varepsilon$ is closed under
$p \mapsto p|\alpha$, and whenever $p \in P_\varepsilon$, $q \in P_\alpha$, and $q \leq p|\alpha$, then also the partial function
$q \land p$ is in $P_\varepsilon$.

So for a given topless $\bar{P}$ there is a well-defined inverse, direct and full CS limit. If $\text{cf}(\varepsilon) > \omega$,
then the direct and the full CS limit coincide. If $\text{cf}(\varepsilon) = \omega$, then the
direct limit and the full CS limit (=inverse limit) differ. Both of them are partial
CS limits, but there are many more possibilities for partial CS limits. By definition,
al of them will yield iterations.

Note that the name “CS limit” is slightly inappropriate, as the size of supports
of conditions is not part of the definition. To give a more specific example, consider
all of them will yield iterations.

CS limits, but there are many more possibilities for partial CS limits. By definition,
all of them will yield iterations.

The following fact can easily be proved by transfinite induction:

**Fact 3.7.** Let $\bar{P}$ be a partial CS iteration. Then for all $\alpha$ the forcing notion $P_\alpha$
is separative.

From now on, all iterations we consider will be partial CS iterations. In this
paper, we will only be interested in proper partial CS iterations, but properness is
not part of the definition of partial CS iteration. (The reader may safely assume
that all iterations are proper.)

Note that separativity of the $Q_\alpha$ implies that all partial CS iterations satisfy the
following (trivially equivalent) properties:

**Fact 3.8.** Let $\bar{P}$ be a topped partial CS iteration of length $\varepsilon$. Then:

1. Let $H$ be $P_\varepsilon$-generic. Then $p \in H$ iff $p|\alpha \in H_\alpha$ for all $\alpha < \varepsilon$.
2. For all $q,p \in P_\varepsilon$, if $q|\alpha \leq^* p|\alpha$ for each $\alpha < \varepsilon$, then $q \leq^* p$.
3. For all $q,p \in P_\varepsilon$, if $q|\alpha \leq^* p|\alpha$ for each $\alpha < \varepsilon$, then $q \parallel p$.

We will be concerned with the following situation:

Assume that $M$ is a nice candidate, $\bar{P}^M$ is (in $M$) a topped partial CS iteration
of length $\varepsilon := \text{sup}(\varepsilon \cap M)$. (Recall that “$\text{cf}(\varepsilon) = \omega$” is absolute between $M$ and $V$, and
that $\text{cf}(\varepsilon) = \omega$ implies $\varepsilon' = \varepsilon$.) Moreover, assume that we already have a system of
$M$-complete coherent embeddings $i_\beta : P^M_\beta \rightarrow P_\beta$ for $\beta \in \varepsilon' \cap M$.
(Recall that any potential partial CS limit of $\bar{P}$ is a subforcing of the full CS limit $P^\text{CS}_\varepsilon$.)

---

27 The reason for this requirement is briefly discussed in Section [6]. Separativity, as well as the
relations $\leq^*$ and $=^*$, are defined on page [243].

28 I.e., they commute with the restriction maps: $i_\alpha(p|\alpha) = i_\beta(p)|\alpha$ for $\alpha < \beta$ and $p \in P^M_\beta$.
It is easy to see that there is only one possibility for an embedding $j : P^{M}_\varepsilon \rightarrow P^{\text{CS}}_{\varepsilon'}$ (in fact, into any potential partial CS limit of $\bar{P}$) that extends the $i_\beta$'s naturally:

**Definition 3.9.** For a topped partial CS iteration $\bar{P}^M$ in $M$ of length $\varepsilon$ and a topless one $\bar{P}$ in $V$ of length $\varepsilon' := \sup(\varepsilon \cap M)$ together with coherent embeddings $i_\beta$, we define $j : P^{M}_\varepsilon \rightarrow P^{\text{CS}}_{\varepsilon'}$, the “canonical extension”, in the obvious way: Given $p \in P^{M}_\varepsilon$, take the sequence of restrictions to $M$-ordinals, apply the functions $i_\beta$, and let $j(p)$ be the union of the resulting coherent sequence.

We do not claim that $j : P^{M}_\varepsilon \rightarrow P^{\text{CS}}_{\varepsilon'}$ is $M$-complete. In the following, we will construct partial CS limits $\bar{P}_{\varepsilon'}$ such that $j : P^{M}_\varepsilon \rightarrow \bar{P}_{\varepsilon'}$ is $M$-complete. (Obviously, one requirement for such a limit is that $j[P^{M}_\varepsilon] \subseteq P_{\varepsilon'}$.) We will actually define two versions: The almost FS (“almost finite support”) and the almost CS (“almost countable support”) limit.

Note that there is only one effect that the “top” of $\bar{P}^M$ (i.e., the forcing $P^{M}_\varepsilon$) has on the canonical extension $j$: It determines the domain of $j$. In particular, it will generally depend on $P^{M}_\varepsilon$ whether or not $j$ is complete. Apart from that, the value of any given $j(p)$ does not depend on $P^{M}_\varepsilon$.

Instead of arbitrary systems of embeddings $i_\alpha$, we will only be interested in “canonical” ones. We assume for notational convenience that $Q^M_\alpha$ is a subset of $Q_\alpha$ (this will naturally be the case in our application anyway).

**Definition 3.10** (The canonical embedding). Let $\bar{P}$ be a partial CS iteration in $V$ and $\bar{P}^M$ a partial CS iteration in $M$, both topped and of length $\varepsilon \in M$. We construct by induction on $\alpha \in (\varepsilon + 1) \cap M$ the canonical $M$-complete embeddings $i_\alpha : P^M_\varepsilon \rightarrow \bar{P}_\alpha$. More precisely, we try to construct them, but it is possible that the construction fails. If the construction succeeds, then we say that “$\bar{P}^M$ (canonically) embeds into $\bar{P}$”, or “the canonical embeddings work”, or just “$\bar{P}$ is over $\bar{P}^M$”, or “over $P^M_\varepsilon$”.

- Let $\alpha = \beta + 1$. By induction hypothesis, $i_\beta$ is $M$-complete, so a $V$-generic filter $H_\beta \subseteq P_\beta$ induces an $M$-generic filter $H^M_\beta := i^{-1}_\beta[H_\beta] \subseteq P^M_\beta$. We require that (in the $H_\beta$ extension) the set $Q^M_\beta[H^M_\beta]$ is an $M[H^M_\beta]$-complete subforcing of $Q_\beta[H_\beta]$. In this case, we define $i_\alpha$ in the obvious way.

- For limit ordinals $\alpha$, let $i_\alpha$ be the canonical extension of the family $(i_\beta)_{\beta \in \alpha \cap M}$. We require that $\bar{P}_\alpha$ contains the range of $i_\alpha$ and that $i_\alpha$ is $M$-complete; otherwise the construction fails. (If $\alpha' := \sup(\alpha \cap M) < \alpha$, then $i_\alpha$ will actually be an $M$-complete map into $\bar{P}_{\alpha'}$, assuming that the requirement is fulfilled.)

In this section we try to construct a partial CS iteration $\bar{P}$ (over a given $\bar{P}^M$) satisfying additional properties.

---

29 For example, if $\varepsilon = \varepsilon' = \omega$ and if $P^M_\omega$ is the finite support limit of a non-trivial iteration, then $j : P^M_\omega \rightarrow P^{\text{CS}}_{\omega}$ is not complete: For notational simplicity, assume that all $Q^M_n$ are (forced to be) Boolean algebras. In $M$, let $c_n$ be (a $P^M_n$-name for) a non-trivial element of $Q^M_n$ (so $\neg c_n$, the Boolean complement, is also non-trivial). Let $p_n$ be the $P^M_n$-condition $(c_0, \ldots, c_{n-1})$, i.e., the truth value of “$c_m \in H(m)$ for all $m < n$”. Let $q_n$ be the $P^M_{n+1}$-condition $(c_0, \ldots, c_{n-1}, \neg c_n)$, i.e., the truth value of “$n$ is minimal with $c_n \notin H(n)$”. In $M$, the set $A = \{q_n : n \in \omega\}$ is a maximal antichain in $P^M_{\omega}$. Moreover, the sequence $(p_n)_{n \in \omega}$ is a decreasing coherent sequence, therefore $i_\omega(p_n)$ defines an element $p_{\omega}$ in $P^{\text{CS}}_{\omega}$, which is clearly incompatible with all $j(q_n)$. Hence $j[A]$ is not maximal.
Remark 3.11. What is the role of \( \varepsilon' := \sup(\varepsilon \cap M) \)? When our inductive construction of \( \tilde{P} \) arrives at \( P_\varepsilon \), where \( \varepsilon' < \varepsilon \), it would be too late\(^{20}\) to take care of \( M \)-completeness of \( i_\varepsilon \) at this stage, even if all \( i_\alpha \) work nicely for \( \alpha \in \varepsilon \cap M \). Note that \( \varepsilon' < \varepsilon \) implies that \( \varepsilon \) is uncountable in \( M \) and that therefore \( P_\varepsilon^M = \bigcup_{\alpha \in \varepsilon \cap M} P_\alpha^M \). So the natural extension \( j \) of the embeddings \( (i_\alpha)_{\alpha \in \varepsilon \cap M} \) has range in \( P_{\varepsilon'}^M \), which will be a complete subforcing of \( P_\varepsilon \). So we have to ensure \( M \)-completeness already in the construction of \( P_{\varepsilon'} \).

For now we just record:

Lemma 3.12. Assume that we have topped iterations \( \tilde{P}^M \) (in \( M \)) of length \( \varepsilon \) and \( \tilde{P} \) (in \( V \)) of length \( \varepsilon' := \sup(\varepsilon \cap M) \), and that for all \( \alpha \in \varepsilon \cap M \) the canonical embedding \( i_\alpha : P_\alpha^M \to P_\alpha \) works. Let \( i_\varepsilon : P_\varepsilon^M \to P_\varepsilon^{\text{cs}} \) be the canonical extension.

1. If \( P_\varepsilon^M \) is (in \( M \)) a direct limit (which is always the case if \( \varepsilon \) has uncountable cofinality), then \( i_\varepsilon \) (might not work, but at least) has range in \( P_{\varepsilon'} \) and preserves incompatibility.

2. If \( i_\varepsilon \) has a range contained in \( P_{\varepsilon'} \) and maps predense sets \( D \subseteq P_\varepsilon^M \) in \( M \) to predense sets \( i_\varepsilon[D] \subseteq P_{\varepsilon'} \), then \( i_\varepsilon \) preserves incompatibility (and therefore works).

Proof. (1) Since \( P_\varepsilon^M \) is a direct limit, the canonical extension \( i_\varepsilon \) has range in \( \bigcup_{\alpha < \varepsilon'} P_\alpha \), which is a subset of any partial CS limit \( P_{\varepsilon'} \). Incompatibility in \( P_\varepsilon^M \) is the same as incompatibility in \( P_\alpha^M \) for sufficiently large \( \alpha \in \varepsilon \cap M \), so by assumption it is preserved by \( i_\alpha \) and hence also by \( i_\varepsilon \).

(2) Fix \( p_1, p_2 \in P_\varepsilon^M \), and assume that their images are compatible in \( P_{\varepsilon'} \); we have to show that they are compatible in \( P_\varepsilon^M \). So fix a generic filter \( H \subseteq P_{\varepsilon'} \) containing \( i_\varepsilon(p_1) \) and \( i_\varepsilon(p_2) \).

In \( M \), we define the following set \( D \):

\[
D := \{ q \in P_\varepsilon^M : (q \leq p_1 \land q \leq p_2) \text{ or } (\exists \alpha < \varepsilon : q \models p_\alpha^M p_1 \models \alpha) \\
\quad \text{or } (\exists \alpha < \varepsilon : q \models p_\alpha^M p_2 \models \alpha) \}.
\]

Using Fact 3.8 it is easy to check that \( D \) is dense. Since \( i_\varepsilon \) preserves predensity, there is \( q \in D \) such that \( i_\varepsilon(q) \in H \). We claim that \( q \) is stronger than \( p_1 \) and \( p_2 \). Otherwise we would have without loss of generality that \( q \models p_\alpha^M p_1 \models \alpha \) for some \( \alpha < \varepsilon \). But the filter \( H \models \alpha \) contains both \( i_\alpha(q|\alpha) \) and \( i_\alpha(p_1|\alpha) \), contradicting the assumption that \( i_\alpha \) preserves incompatibility. \( \square \)

3.C. Almost finite support iterations. Recall Definition 3.9 (of the canonical extension) and the setup that was described there: We have to find a subset \( P_{\varepsilon'} \) of \( P_{\varepsilon'}^{\text{cs}} \) such that the canonical extension \( j : P_{\varepsilon'}^M \to P_{\varepsilon'} \) is \( M \)-complete.

We now define the almost finite support limit. (The direct limit will in general not do, as it may not contain the range \( j[P_{\varepsilon'}^M] \). The almost finite support limit is

\(^{20}\) For example, let \( \varepsilon = \omega_1 \) and \( \varepsilon' = \omega_1 \cap M \). Assume that \( P_\omega^M \) is (in \( M \)) a (or the unique) partial CS limit of a non-trivial iteration. Assume that we have a topless iteration \( P \) of length \( \varepsilon' \) in \( V \) such that the canonical embeddings work for all \( \alpha \in \omega_1 \cap M \). If we set \( P_{\varepsilon'} \) to be the full CS limit, then we cannot further extend it to any iteration of length \( \omega_1 \) such that the canonical embedding \( i_\omega \) works. Let \( p_\alpha \) and \( q_\alpha \) be as in footnote 20. In \( M \), the set \( A = \{ q_\alpha : \alpha \in \omega_1 \} \) is a maximal antichain, and the sequence \( (p_\alpha)_{\alpha \in \omega_1} \) is a decreasing coherent sequence. But in \( V \) there is an element \( p_{\varepsilon'} \in P_{\varepsilon'}^{\text{cs}} \) with \( p_\alpha \models j(p_\alpha) \) for all \( \alpha \in \varepsilon \cap M \). This condition \( p_{\varepsilon'} \) is clearly incompatible with all elements of \( j[A] = \{ j(q_\alpha) : \alpha \in \varepsilon \cap M \} \). Hence \( j[A] \) is not maximal.
the obvious modification of the direct limit, it is the smallest partial CS limit \( P_{\varepsilon'} \) such that \( j[P_{\varepsilon}^M] \subseteq P_{\varepsilon'} \), and it indeed turns out to be \( M \)-complete as well.

**Definition 3.13.** Let \( \varepsilon \) be a limit ordinal in \( M \), and let \( \varepsilon' := \sup(\varepsilon \cap M) \). Let \( \bar{P}^M \) be a topped iteration in \( M \) of length \( \varepsilon \), and let \( \bar{P} \) be a topless iteration in \( V \) of length \( \varepsilon' \). Assume that the canonical embeddings \( i_\alpha \) work for all \( \alpha \in \varepsilon \cap M = \varepsilon' \cap M \). Let \( i_\varepsilon \) be the canonical extension. We define the *almost finite support limit* of \( \bar{P} \) over \( \bar{P}^M \) (or almost FS limit) as the following subforcing \( P_{\varepsilon'} \) of \( P_{\varepsilon}^{CS} \):

\[
P_{\varepsilon'} := \{ q \land i_\varepsilon(p) \in P_{\varepsilon}^{CS} : p \in P_{\varepsilon}^M \land q \in P_{\alpha} \text{ for some } \alpha \in \varepsilon \cap M \}
\]

such that \( q \leq_{P_{\alpha}} i_\alpha(p|\alpha) \).

Note that for \( \text{cf}(\varepsilon) > \omega \), the almost FS limit is equal to the direct limit, as each \( p \in P_{\varepsilon}^M \) is in fact in \( P_{\alpha}^M \) for some \( \alpha \in \varepsilon \cap M \), so \( i_\varepsilon(p) = i_\alpha(p) \in P_{\alpha} \).

**Lemma 3.14.** Assume that \( \bar{P} \) and \( \bar{P}^M \) are as above and let \( P_{\varepsilon'} \) be the almost FS limit. Then \( P_{\varepsilon}^+ \) is a partial CS iteration, and \( i_\varepsilon \) works, i.e., \( i_\varepsilon \) is an \( M \)-complete embedding from \( P_{\varepsilon}^M \) to \( P_{\varepsilon'} \). (As \( P_{\varepsilon'} \) is a complete subforcing of \( P_{\varepsilon} \), this also implies that \( i_\varepsilon \) is \( M \)-complete from \( P_{\varepsilon}^M \) to \( P_{\varepsilon'} \)).

**Proof.** It is easy to see that \( P_{\varepsilon'} \) is a partial CS limit and contains the range \( i_\varepsilon[P_{\varepsilon}^M] \). We now show preservation of predensity; this implies \( M \)-completeness by Lemma 3.12.

Let \( (p_j)_{j \in J} \in M \) be a maximal antichain in \( P_{\varepsilon}^M \). (Since \( P_{\varepsilon}^M \) does not have to be ccc in \( M \), \( J \) can have any cardinality in \( M \).) Let \( q \land i_\varepsilon(p) \) be a condition in \( P_{\varepsilon'} \). (If \( \varepsilon' < \varepsilon \), i.e., if \( \text{cf}(\varepsilon) > \omega \), then we can choose \( p \) to be the empty condition.) Fix \( \alpha \in \varepsilon \cap M \) such that \( q \in P_{\alpha} \). Let \( H_{\alpha} \) be \( P_{\alpha} \)-generic and contain \( q \), so \( p|\alpha \) is in \( H_{\alpha}^M \). Now in \( M[H_{\alpha}^M] \) the set \( \{ p_j : j \in J, p_j \in P_{\varepsilon}^M/H_{\alpha}^M \} \) is predense in \( P_{\varepsilon}^M/H_{\alpha}^M \) (since this is forced by the empty condition in \( P_{\alpha}^M \)). In particular, \( p \) is compatible with some \( p_j \), witnessed by \( p' \leq p, p_j \in P_{\varepsilon}^M/H_{\alpha}^M \).

We can find \( q' \leq_{P_{\alpha}} q \) deciding \( j \) and \( p' \); since certainly \( q' \leq^{*} i_\alpha(p'|\alpha) \), we may assume even \( \leq \) without loss of generality. Now \( q' \land i_\varepsilon(p') \leq q \land i_\varepsilon(p) \) (since \( q' \leq q \) and \( p' \leq p \)) and \( q' \land i_\varepsilon(p') \leq i_\varepsilon(p_j) \) (since \( p' \leq p_j \)). \( \square \)

**Definition and Claim 3.15.** Let \( \bar{P}^M \) be a topped partial CS iteration in \( M \) of length \( \varepsilon \). We can construct by induction on \( \beta \in \varepsilon + 1 \) an *almost finite support iteration* \( \bar{P} \) over \( \bar{P}^M \) (or almost FS iteration) as follows:

1. As an induction hypothesis we assume that the canonical embedding \( i_\alpha \) works for all \( \alpha \in \beta \cap M \). (So the notation \( M[H_{\alpha}^M] \) makes sense.)
2. Let \( \beta = \alpha + 1 \). If \( \alpha \in M \), then we can use any \( Q_{\alpha} \) provided that (it is forced that) \( Q_{\alpha}^M \) is an \( M[H_{\alpha}^M] \)-complete subforcing of \( Q_{\alpha} \). (If \( \alpha \notin M \), then there is no restriction on \( Q_{\alpha} \).)
3. Let \( \beta \in M \) and \( \text{cf}(\beta) = \omega \). Then \( P_{\beta} \) is the almost FS limit of \( (P_{\alpha}, Q_{\alpha})_{\alpha < \beta} \) over \( P_{\beta}^M \).
4. Let \( \beta \in M \) and \( \text{cf}(\beta) > \omega \). Then \( P_{\beta} \) is again the almost FS limit of \( (P_{\alpha}, Q_{\alpha})_{\alpha < \beta} \) over \( P_{\beta}^M \) (which also happens to be the direct limit).
5. For limit ordinals not in \( M \), \( P_{\beta} \) is the direct limit.

So the claim includes that the resulting \( \bar{P} \) is a (topped) partial CS iteration of length \( \varepsilon \) over \( P_{\varepsilon}^M \) (i.e., the canonical embeddings \( i_\alpha \) work for all \( \alpha \in (\varepsilon + 1) \cap M \)), where we only assume that the \( Q_{\alpha} \) satisfy the obvious requirement given in [2].
(Note that we can always find some suitable $Q_\alpha$ for $\alpha \in M$, for example, we can just take $Q_\alpha^M$ itself.)

**Proof.** We have to show (by induction) that the resulting sequence $\tilde{P}$ is a partial CS iteration and that $\tilde{P}^M$ embeds into $\bar{P}$. For successor cases, there is nothing to do. So assume that $\alpha$ is a limit. If $P_\alpha$ is a direct limit, it is trivially a partial CS limit. If $P_\alpha$ is an almost FS limit, then the easy part of Lemma [3.14] shows that it is a partial CS limit.

So it remains to show that for a limit $\alpha \in M$, the (naturally defined) embedding $i_\alpha : P_\alpha^M \to P_\alpha$ is $M$-complete. This was the main claim in Lemma 3.14 \[ \square \]

The following lemma is natural and easy.

**Lemma 3.16.** Assume that we construct an almost FS iteration $\bar{P}$ over $\tilde{P}^M$ where each $Q_\alpha$ is (forced to be) ccc. Then $P_\varepsilon$ is ccc (and in particular proper).

**Proof.** We show that $P_\alpha$ is ccc by induction on $\alpha \leq \varepsilon$. For successors, we use that $Q_\alpha$ is ccc. For $\alpha$ of uncountable cofinality, we know that we took the direct limit coboundedly often (and all $P_\beta$ are ccc for $\beta < \alpha$), so by a result of Solovay $P_\alpha$ is again ccc. For $\alpha$ a limit of countable cofinality not in $M$, just use that all $P_\beta$ are ccc for $\beta < \alpha$ and the fact that $P_\alpha$ is the direct limit. This leaves the case that $\alpha \in M$ has countable cofinality, i.e., $P_\alpha$ is the almost FS limit. Let $A \subseteq P_\alpha$ be uncountable. Each $a \in A$ has the form $q \land i_\alpha(p)$ for $p \in P_\alpha^M$ and $q \in \bigcup_{\gamma < \alpha} P_\gamma$. We can thin out the set $A$ such that all $p$ are the same and all $q$ are in the same $P_\gamma$. So there have to be compatible elements in $A$. \[ \square \]

All almost FS iterations that we consider in this paper will satisfy the countable chain condition (and hence in particular be proper).

We will need a variant of this lemma for $\sigma$-centered forcing notions.

**Lemma 3.17.** Assume that we construct an almost FS iteration $\bar{P}$ over $\tilde{P}^M$ where only countably many $Q_\alpha$ are non-trivial (e.g., only those with $\alpha \in M$) and where each $Q_\alpha$ is (forced to be) $\sigma$-centered. Then $P_\varepsilon$ is $\sigma$-centered as well.

**Proof.** By induction, the direct limit of countably many $\sigma$-centered forcings is $\sigma$-centered, as is the almost FS limit of $\sigma$-centered forcings (to color $q \land i_\alpha(p)$, use $p$ itself together with the color of $q$). \[ \square \]

We will actually need two variants of the almost FS construction: Countably many models $M^n$ and starting the almost FS iteration with some $\alpha_0$.

First, we can construct an almost FS iteration, not just over one iteration $\tilde{P}_n^M$, but over an increasing chain of iterations. Analogously to Definition [3.13] and Lemma [3.14] we can show:

**Lemma 3.18.** For each $n \in \omega$, let $M^n$ be a nice candidate, and let $\tilde{P}_n^M$ be a topped partial CS iteration in $M^n$ of length[31] $\varepsilon \in M^0$ of countable cofinality such that $M^n \in M^n$ and $M^n$ thinks that $P_m^m$ canonically embeds into $P_m^n$, for all $m < n$. Let $\bar{P}$ be a topless iteration of length $\varepsilon$ into which all $P_m^n$ canonically embed.

Then we can define the almost FS limit $P_\varepsilon$ over $(\tilde{P}_n^M)_{n \in \omega}$ as follows: Conditions in $P_\varepsilon$ are of the form $q \land i_\alpha^n(p)$, where $n \in \omega$, $p \in P_\varepsilon^n$, and $q \in P_\alpha$ for some $\alpha \in M^n \cap \varepsilon$ with $q \leq i_\alpha^n(p|\alpha)$. Then $P_\varepsilon$ is a partial CS limit over each $\tilde{P}_n^M$.

[31]Or only $\varepsilon \in M^{\omega_0}$ for some $\omega_0$. 

As before, we get the following corollary:

**Corollary 3.19.** Given $M^n$ and $\bar{P}^n$ as above, we can construct a topped partial CS iteration $\bar{P}$ such that each $P^n$ embeds $M^n$ completely into it; we can choose $Q_\alpha$ as we wish (subject to the obvious restriction that each $Q_\alpha^n$ is an $M^n[H^n_\alpha]$-complete subforcing). If we always choose $Q_\alpha$ to be ccc, then $\bar{P}$ is ccc; this is the case if we set $Q_\alpha$ to be the union of the (countable) sets $Q_\alpha^n$.

**Proof.** We can define $P_\alpha$ by induction. If $\alpha \in \bigcup_{n \in \omega} M^n$ has countable cofinality, then we use the almost FS limit as in Lemma 3.18. Otherwise we use the direct limit. If $\alpha \in M^n$ has uncountable cofinality, then $\alpha' := \sup(\alpha \cap M)$ is an element of $M^{n+1}$. In our induction we have already considered $\alpha'$ and have defined $P_\alpha'$ by Lemma 3.18 (applied to the sequence $(\bar{P}^{n+1}, \bar{P}^{n+2}, \ldots)$). This is sufficient to show that $i^n_\alpha : P^n \to P_{\alpha'} \ll P_\alpha$ is $M^n$-complete. \hfill $\square$

Second, we can start the almost FS iteration after some $\alpha_0$ (i.e., $\bar{P}$ is already given up to $\alpha_0$, and we can continue it as an almost FS iteration up to $\varepsilon$) and get the same properties that we previously showed for the almost FS iteration, but this time for the quotient $P_\varepsilon/P_{\alpha_0}$. In more detail:

**Lemma 3.20.** Assume that $P^M$ is in $M$ a (topped) partial CS iteration of length $\varepsilon$ and that $\bar{P}$ is in $V$ a topped partial CS iteration of length $\alpha_0$ over $P^M[\alpha_0]$ for some $\alpha_0 \in \varepsilon \cap M$. Then we can extend $\bar{P}$ to a (topped) partial CS iteration of length $\varepsilon$ over $P^M$, as in the almost FS iteration (i.e., using the almost FS limit at limit points $\beta > \alpha_0$ with $\beta \in M$ of countable cofinality, and the direct limit everywhere else).

We can use any $Q_\alpha$ for $\alpha \geq \alpha_0$ (provided $Q^M_\alpha$ is an $M[H^M_\alpha]$-complete subforcing of $Q_\alpha$). If all $Q_\alpha$ are ccc, then $P_{\alpha_0}$ forces that $P_\varepsilon/H_{\alpha_0}$ is ccc (in particular, proper). If moreover all $Q_\alpha$ are $\sigma$-centered and only countably many are non-trivial, then $P_{\alpha_0}$ forces that $P_\varepsilon/H_{\alpha_0}$ is $\sigma$-centered.

### 3.D. Almost countable support iterations

“Almost countable support iterations $P^n$ (over a given iteration $P^M$ in a candidate $M$) will have the following two crucial properties: There is a canonical $M$-complete embedding of $P^M$ into $\bar{P}$, and $\bar{P}$ preserves a given random real (similar to the usual countable support iterations).

**Definition and Claim 3.21.** Let $P^M$ be a topped partial CS iteration in $M$ of length $\varepsilon$. We can construct by induction on $\beta \in \varepsilon + 1$ the almost countable support iteration $\bar{P}$ over $P^M$ (or almost CS iteration):

1. As an induction hypothesis, we assume that the canonical embedding $i_\alpha$ works for every $\alpha \in \beta \cap M$. We set
   
   $$(3.22) \quad \delta := \min(M \setminus \beta), \quad \delta' := \sup(\alpha + 1 : \alpha \in \delta \cap M).$$

   Note that $\delta' \leq \beta \leq \delta$.

2. Let $\beta = \alpha + 1$. We can choose any desired forcing $Q_\alpha$; if $\beta \in M$ we of course require that

   $$(3.23) \quad Q^M_\alpha$$

   is an $M[H^M_\alpha]$-complete subforcing of $Q_\alpha$.

   This defines $P_\beta$.

3. Let $\text{cf}(\beta) > \omega$. Then $P_\beta$ is the direct limit.

---

[32]So for successors $\beta \in M$, we have $\delta' = \beta = \delta$. For $\beta \in M$ limit, $\beta = \delta$ and $\delta'$ is as in Definition 3.21.
Let cf(β) = ω and assume that β ∈ M (so M ∩ β is cofinal in β and δ′ = β = δ). We define P_β = P_β as the union of the following two sets:

- The almost FS limit of (P_α, Q_α)_{α < δ}; see Definition 3.13.
- The set P^gen_δ of M-generic conditions q ∈ P^CS_δ, i.e., those which satisfy

  \[ q \Vdash_{P^CS_δ} \bar{i}^{-1}_δ[H_{P^CS_δ}] \subseteq P^M_δ \text{ is M-generic.} \]

(4) Let cf(β) = ω and assume that β ∈ M (so M ∩ β is cofinal in β and δ′ = β = δ). We define P_β = P_β as the union of the following two sets:

- The almost FS limit of (P_α, Q_α)_{α < δ}; see Definition 3.13.
- The set P^gen_δ of M-generic conditions q ∈ P^CS_δ, i.e., those which satisfy

  \[ q \Vdash_{P^CS_δ} \bar{i}^{-1}_δ[H_{P^CS_δ}] \subseteq P^M_δ \text{ is M-generic.} \]

(5) Let cf(β) = ω and assume that β /∈ M but M ∩ β is cofinal in β, so δ′ = β < δ. We define P_β = P_β as the union of the following two sets:

- The direct limit of (P_α, Q_α)_{α < δ′}.
- The set P^gen_{δ'} of M-generic conditions q ∈ P^CS_{δ'}, i.e., those which satisfy

  \[ q \Vdash_{P^CS_{δ'}} \bar{i}^{-1}_{δ'}[H_{P^CS_{δ'}}] \subseteq P^M_{δ'} \text{ is M-generic.} \]

(Note that the M-generic conditions form an open subset of P^CS_{δ'} = P^CS_{δ'}.)

(6) Let cf(β) = ω and M ∩ β not cofinal in β (so β /∈ M). Then P_β is the full CS limit of (P_α, Q_α)_{α < β} (see Definition 3.5).

So the claim is that for every choice of Q_α (with the obvious restriction (3.23)), this construction always results in a partial CS iteration P over P^M. The proof is a bit cumbersome; it is a variant of the usual proof that properness is preserved in countable support iterations (see e.g. [Gol93]).

We will use the following fact in M (for the iteration P^M):

Let P be a topped iteration of length ϵ. Let α_1 ≤ α_2 ≤ β ≤ ϵ.

Let p_1 be a P_{α_2}-name for a condition in P_ε, and let D be an open dense set of P_β. Then there is a P_{α_2}-name p_2 for a condition in D such that the empty condition of P_{α_2} forces p_2 ≤ p_1↾β, and if p_1 is in P_ε/H_{α_2}, then the condition p_2 is as well.

(Proof: Work in the P_{α_2}-extension. We know that p' := p_1↾β is a P_β-condition. We now define p_2 as follows: If p' /∈ P_β/H_{α_2} (which is equivalent to p_1 /∈ P_ε/H_{α_2}), then we choose any p_2 ≤ p' in D (which is dense in P_β). Otherwise (using that D ∩ P_β/H_{α_2} is dense in P_β/H_{α_2}) we can choose p_2 ≤ p' in D ∩ P_β/H_{α_2}.)

The following easy fact will also be useful:

Let P be a subforcing of Q. We define P↾p := {r ∈ P : r ≤ p}.

Assume that p ∈ P and P↾p = Q↾p. Then for any P-name x and any formula φ(x) we have p \Vdash_P φ(x) if p \Vdash_Q φ(x).

We now prove the following statement by induction on β ≤ ϵ (which includes that the Definition and Claim 3.21 works up to β). Let δ, δ' be as in (3.22).

Lemma 3.26. (a) The topped iteration P of length β is a partial CS iteration.

(b) The canonical embedding i_δ : P^M_δ → P_{δ'} works, hence i_δ : P^M_δ → P_δ also works.

(c) Moreover, assume that

- α ∈ M ∩ δ,
- p ∈ M is a P^M_α-name of a P^M_δ-condition,
- q ∈ P_α forces (in P_α) that p↾α[H^M_α] is in H^M_α.

Then there is a q^⁺ ∈ P_{δ'} (and therefore in P_δ) extending q and forcing that p[H^M_δ] is in H^M_δ.
Proof. First let us deal with the trivial cases. It is clear that we always get a partial CS iteration.

- Assume that $\beta = \beta_0 + 1 \in M$, i.e., $\delta = \delta' = \beta$. It is clear that $i_\delta$ works. To get $q^+$, first extend $q$ to some $q' \in P_{\beta_0}$ (by induction hypothesis), then define $q^+$ extending $q'$ by $q^+(\beta_0) := p(\beta_0)$.
- If $\beta = \beta_0 + 1 \notin M$, there is nothing to do.
- Assume that $\text{cf}(\beta) > \omega$ (whether $\beta \in M$ or not). Then $\delta' < \beta$. So $i_\delta : P_\delta^M \to P_{\beta'}$ works by induction, and similarly (c) follows from the inductive assumption. (Use the inductive assumption for $\beta = \delta'$; the $\delta$ that we got at that stage is the same as the current $\delta$, and the $q^+$ we obtained at that stage will still satisfy all requirements at the current stage.)
- Assume that $\text{cf}(\beta) = \omega$ and that $M \cap \beta$ is bounded in $\beta$. Then the proof is the same as in the previous case.

We are left with the cases corresponding to (4) and (5) of Definition 3.21: $\text{cf}(\beta) = \omega$ and $M \cap \beta$ is cofinal in $\beta$. So either $\beta \in M$, then $\delta' = \beta = \delta$, or $\beta \notin M$, then $\delta' = \beta < \delta$ and $\text{cf}(\delta) > \omega$.

We leave it to the reader to check that $P_\beta$ is indeed a partial CS limit. The main point is to see that for all $p, q \in P_\beta$ the condition $q \land p$ is in $P_\beta$ as well, provided $q \in P_\alpha$ and $q \leq p|\alpha$ for some $\alpha < \beta$. If $p \in P_\beta^\text{gen}$, then this follows because $P_\beta^\text{gen}$ is open in $P_\beta^\text{CS}$; the other cases are immediate from the definition (by induction).

We now turn to claim (c). Assume $q \in P_\alpha$ and $p \in M$ are given; $\alpha \in M \cap \delta$.

Let $(D_n)_{n \in \omega}$ enumerate all dense sets of $P_\delta^M$ which lie in $M$, and let $(\alpha_n)_{n \in \omega}$ be a sequence of ordinals in $M$ which is cofinal in $\beta$, where $\alpha_0 = \alpha$.

Using (3.2.4) in $M$, we can find a sequence $(p_n)_{n \in \omega}$ satisfying the following in $M$, for all $n > 0$:

- $p_0 = p$.
- $p_n \in M$ is a $P_\alpha^M$-name of a $P_\delta^M$-condition in $D_n$.
- $\models_{P_\alpha^M} p_n \leq_{P_\delta^M} p_{n-1}$.
- $\models_{P_\alpha^M}$ $p_n \models_{P_\alpha^M} |\alpha_n \in H_\alpha^M$, then $p_n|\alpha_n \in H_\alpha^M$ as well.

Using the inductive assumption for the $\alpha_n$’s, we can now find a sequence $(q_n)_{n \in \omega}$ of conditions satisfying the following:

- $q_0 = q$, $q_n \in P_\alpha^*$.
- $q_n|\alpha_{n-1} = q_{n-1}$.
- $q_n \models_{P_\alpha^*} p_{n-1}|\alpha_n \in H_\alpha^M$, so also $p_n|\alpha_n \in H_\alpha^M$.

Let $q^+ \in P_\beta^\text{CS}$ be the union of the $q_n$. Then for all $n$:

1. $q_n \models_{P_\beta^\text{CS}} p_n|\alpha_n \in H_{\alpha_n}^M$, so also $q^+$ forces this.
   (Using induction on $n$.)
2. For all $n$ and all $m \geq n$: $q^+ \models_{P_\beta^\text{CS}} p_m|\alpha_m \in H_{\alpha_m}^M$, so also $p_n|\alpha_m \in H_{\alpha_m}^M$.
   (As $p_m \leq p_n$.)
3. $q^+ \models_{P_\beta^\text{CS}} p_n \in H_\delta^M$.
   (Recall that $P_\beta^\text{CS}$ is separative; see Fact 3.7. So $i_\delta(p_n) \in H_\delta$ iff $i_\alpha_n(p|\alpha_m) \in H_\alpha^M$ for all large $m$.)

As $q^+ \models_{P_\beta^\text{CS}} p_n \in D_n \cap H_\delta^M$, we conclude that $q^+ \in P_\beta^\text{gen}$ (using Lemma 3.12 applied to $P_\beta^\text{CS}$). In particular, $P_\beta^\text{gen}$ is dense in $P_\beta$: Let $q \land i_\delta(p)$ be an element of
the almost FS limit, so \( q \in P_\alpha \) for some \( \alpha < \beta \). Now find a generic \( q^+ \) extending \( q \) and stronger than \( i_\delta(p) \); then \( q^+ \leq q \wedge i_\delta(p) \).

It remains to show that \( i_\delta \) is \( M \)-complete. Let \( A \in M \) be a maximal antichain of \( P^M_\delta \), and let \( p \in P_\beta \). Assume towards a contradiction that \( p \) forces in \( P_\beta \) that \( i_\delta^{-1}[H_\beta] \) does not intersect \( A \) in exactly one point.

Since \( P^\text{gen}_\beta \) is dense in \( P_\beta \), we can find some \( q \leq p \) in \( P^\text{gen}_\beta \). Let

\[
P' := \{ r \in P^\text{CS}_\beta : r \leq q \} = \{ r \in P_\beta : r \leq q \},
\]

where the equality holds because \( P^\text{gen}_\beta \) is open in \( P^\text{CS}_\beta \).

Let \( \Gamma \) be the canonical name for a \( P^* \)-generic filter, i.e.: \( \Gamma := \{ (\bar{r}, r) : r \in P' \} \). Let \( R \) be either \( P^\text{CS}_\beta \) or \( P_\beta \). We write \( (\Gamma)_R \) for the filter generated by \( \Gamma \) in \( R \), i.e.,

\[
(\Gamma)_R := \{ r \in R : (\exists r' \in \Gamma) r' \leq r \}.
\]

(3.27)

\[ q \Vdash_R H_R = (\Gamma)_R. \]

We now see that the following hold:

- \( q \Vdash_{P_\beta} i_\delta^{-1}[H_{P_\beta}] \) does not intersect \( A \) in exactly one point. (By assumption.)
- \( q \Vdash_{P_\beta} i_\delta^{-1}[(\Gamma)_{P_\beta}] \) does not intersect \( A \) in exactly one point. (By (3.27).)
- \( q \Vdash_{P^\text{CS}_\beta} i_\delta^{-1}[(\Gamma)_{P^\text{CS}_\beta}] \) does not intersect \( A \) in exactly one point. (By (3.25).)
- \( q \Vdash_{P^\text{CS}_\beta} i_\delta^{-1}[(\Gamma)_{P^\text{CS}_\beta}] \) does not intersect \( A \) in exactly one point. (Because \( i_\delta \) maps \( A \) into \( P^\text{CS}_\beta \subseteq P_\beta \), so \( A \cap i_\delta^{-1}[\langle Y \rangle_{P_\beta}] = A \cap i_\delta^{-1}[\langle Y \rangle_{P^\text{CS}_\beta}] \) for all \( Y \).)
- \( q \Vdash_{P^\text{CS}_\beta} i_\delta^{-1}[H_{P^\text{CS}_\beta}] \) does not intersect \( A \) in exactly one point. (Again by (3.27).)

But this, according to the definition of \( P^\text{gen}_\beta \), implies \( q \notin P^\text{gen}_\beta \), a contradiction. \( \square \)

We can also show that the almost CS iteration of proper forcings \( Q_\alpha \) is proper. (We do not really need this fact, as we could allow non-proper iterations in our preparatory forcing; see Section 6.A(4). In some sense, \( M \)-completeness replaces properness, so the proof of \( M \)-completeness was similar to the “usual” proof of properness.)

**Lemma 3.28.** Assume that in Definition and Claim 3.21 every \( Q_\alpha \) is (forced to be) proper. Then also each \( P_\delta \) is proper.

**Proof.** By induction on \( \delta \leq \varepsilon \) we prove that for all \( \alpha < \delta \) the quotient \( P_\delta/H_\alpha \) is (forced to be) proper. We use the following facts about properness:

(3.29)

If \( P \) is proper and \( P \) forces that \( Q \) is proper, then \( P \ast Q \) is proper.

(3.30)

If \( \bar{P} \) is an iteration of length \( \omega \) and if each \( Q_\alpha \) is forced to be proper, then the inverse limit \( P_\omega \) is proper, as are all quotients \( P_\omega/H_\alpha \).

(3.31)

If \( \bar{P} \) is an iteration of length \( \delta \) with \( \text{cf}(\delta) > \omega \), and if all quotients \( P_\beta/H_\alpha \) (for \( \alpha < \beta < \delta \)) are forced to be proper, then the direct limit \( P_\delta \) is proper, as are all quotients \( P_\delta/H_\alpha \).

If \( \delta \) is a successor, then our inductive claim easily follows from the inductive assumption together with (3.29).

Let \( \delta \) be a limit of countable cofinality, say \( \delta = \sup_n \delta_n \). Define an iteration \( P' \) of length \( \omega \) with \( Q'_n := P_{\delta_{n+1}}/H_{\delta_n} \). (Each \( Q'_n \) is proper by inductive assumption.)
There is a natural forcing equivalence between $P^\delta_{\text{CS}}$ and $P^\omega_{\text{CS}}$, the full CS limit of $\bar{P}$.

Let $N \prec H(\chi^*)$ contain $\bar{P}, P_\delta, P', M, P^M$. Let $p \in P_\delta \cap N$. Without loss of generality, $p \in P^\text{gen}_\delta$. So below $p$ we can identify $P_\delta$ with $P^\delta_{\text{CS}}$ and hence with $P^\omega_{\text{CS}}$; now apply (3.30).

The case of uncountable cofinality is similar, using (3.31) instead. \hfill \Box

Recall the definition of $\subseteq_n$ and $\subseteq$ from Definition 1.26, the notion of (quick) interpretation $Z^*$ (of a name $Z$ of a code for a null set) and the definition of local preservation of randomness from Definition 1.50. Recall that we have seen in Corollaries 1.51 and 2.22.

**Lemma 3.32.**
- If $Q^M$ is an ultralaver forcing in $M$ and $r$ a real, then there is an ultralaver forcing $Q$ over $Q^M$ locally preserving randomness of $r$ over $M$.
- If $Q^M$ is a Janus forcing in $M$ and $r$ a real, then there is a Janus forcing $Q$ over $Q^M$ locally preserving randomness of $r$ over $M$.

We will prove the following preservation theorem:

**Lemma 3.33.** Let $\bar{P}$ be an almost CS iteration (of length $\varepsilon$) over $\bar{P}^M$, $r$ random over $M$, and $p \in P^M_\varepsilon$. Assume that each $P_\alpha$ forces that $Q^M_{\alpha}$ locally preserves randomness of $r$ over $M[H^M_\alpha]$. Then there is some $q \leq p$ in $P_\varepsilon$ forcing that $r$ is random over $M[H^M_\varepsilon]$.

What we will actually need is the following variant:

**Lemma 3.34.** Assume that $\bar{P}^M$ is in $M$ a topped partial CS iteration of length $\varepsilon$, and we already have some topped partial CS iteration $\bar{P}$ over $\bar{P}^M|\alpha_0$ of length $\alpha_0 \in M \cap \varepsilon$. Let $\tau$ be a $P_{\alpha_0}$-name of a random real over $M[H^M_{\alpha_0}]$. Assume that we extend $\bar{P}$ to length $\varepsilon$ as an almost CS iteration using forings $Q_\alpha$ which locally preserve the randomness of $\tau$ over $M[H^M_{\alpha}]$, witnessed by a sequence $(D^M_{\alpha,-})_{k \in \omega}$. Let $p \in P^M_\varepsilon$. Then we can find a $q \leq p$ in $P_\varepsilon$ forcing that $\tau$ is random over $M[H^M_\varepsilon]$.

Actually, we will only prove the two previous lemmas under the following additional assumption (which is enough for our application and saves some unpleasant work). This additional assumption is not really necessary; without it, we could use the method of [GK06] for the proof.

**Assumption 3.35.**
- For each $\alpha \in M \cap \varepsilon$, $(P^M_\alpha$ forces that) $Q^M_\alpha$ is either trivial or adds a new $\omega$-sequence of ordinals. Note that in the latter case we can assume without loss of generality that $\bigcap_{n \in \omega} D^M_n = \emptyset$ (and, of course, that the $D^M_n$ are decreasing).
- Moreover, we assume that already in $M$ there is a set $T \subseteq \varepsilon$ such that $P^M_\alpha$ forces: $Q^M_\alpha$ is trivial iff $\alpha \in T$. (So whether $Q^M_\alpha$ is trivial or not does not depend on the generic filter below $\alpha$; it is already decided in the ground model.)

---

33 Of course our official definition of almost CS iteration assumes that we start the construction at 0, so we modify this definition in the obvious way.

34 More specifically, $Q^M_\alpha = \{\emptyset\}$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
The result will follow as a special case of the following lemma, which we prove by induction on $\beta$. (Note that this is a refined version of the proof of Lemma 3.26 and is similar to the proof of the preservation theorem in \cite[5.13]{Gol93}).

**Definition 3.36.** Under the assumptions of Lemma 3.34 and Assumption 3.35, let $Z$ be a $P_\delta$-name, $\alpha_0 \leq \alpha < \delta$, and let $\bar{p} = (p_k)_{k \in \omega}$ be a sequence of $P_\alpha$-names of conditions in $P_\delta/H_\alpha$. Let $Z^*$ be a $P_\delta$-name.

We say that $(\bar{p}, Z^*)$ is a quick interpretation of $Z$ if $\bar{p}$ interprets $Z$ as $Z^*$ (i.e., $P_\alpha$ forces that $p_k$ forces $Z|k = Z^*|k$ for all $k$), and moreover:

- $\beta \geq \alpha$ be minimal with $Q^M_\beta$ non-trivial (if such a $\beta$ exists):
  - $P_\beta$ forces that the sequence $(p_k(\beta))_{k \in \omega}$ is quick in $Q^M_\beta$, i.e., $p_k(\beta) \in D_k^M$ for all $k$.

It is easy to see that:

(3.37) For every name $Z$ there is a quick interpretation $(\bar{p}, Z^*)$.

**Lemma 3.38.** Under the same assumptions as above, let $\beta$, $\delta$, $\delta'$ be as in (3.22) (so in particular we have $\delta' \leq \beta \leq \delta \leq \varepsilon$).

Assume that

- $\alpha \in M \cap \delta (= M \cap \beta)$ and $\alpha \geq \alpha_0$ (so $\alpha < \delta'$),
- $p \in M$ is a $P^M_\delta$-name of a $P^M_\delta$-condition,
- $Z \in M$ is a $P^M_\delta$-name of a code for null set,
- $Z^* \in M$ is a $P^M_\alpha$-name of a code for a null set,
- $P^\delta_\alpha$ forces: $\bar{p} = (p_k)_{k \in \omega} \in M$ is a quick sequence in $P^M_\delta/H^M_\alpha$ interpreting $Z$ as $Z^*$ (as in Definition 3.36),
- $P^\delta_\alpha$ forces: if $p|\alpha \in H^M_\alpha$, then $p^0 \leq p$,
- $q \in P_\alpha$ forces $p|\alpha \in H^M_\alpha$,
- $q$ forces that $r$ is random over $M[H^M_\alpha]$, so in particular there is (in $V$) a $P_\alpha$-name $c_0$ below $q$ for the minimal $c$ with $Z^* \subseteq c r$.

Then there is a condition $q^+ \in P^\alpha_\delta$, extending $q$, and forcing the following:

- $p \in H^M_\delta$,
- $r$ is random over $M[H^M_\delta]$,
- $Z \subseteq c_0 r$.

We actually claim a slightly stronger version, where instead of $Z^*$ and $Z$ we have finitely many codes for null sets and names of codes for null sets, respectively. We will use this stronger claim as an inductive assumption, but for notational simplicity we only prove the weaker version; it is easy to see that the weaker version implies the stronger version.

**Proof.** The nontrivial successor case: $\beta = \gamma + 1 \in M$.

If $Q^M_\gamma$ is trivial, there is nothing to do.

Now let $\gamma_0 \geq \alpha$ be minimal with $Q^M_{\gamma_0}$ non-trivial. We will distinguish two cases: $\gamma = \gamma_0$ and $\gamma > \gamma_0$.

Consider first the case that $\gamma = \gamma_0$. Work in $V[H_\gamma]$, where $q \in H_\gamma$. Note that $M[H^M_\gamma] = M[H^M_\gamma]$. So $r$ is random over $M[H^M_\gamma]$, and $(p^k(\gamma))_{k \in \omega}$ quickly interprets $Z$ as $Z^*$ in $Q^M_\gamma$. Now let $q^+|\gamma = q$ and use the fact that $Q_\gamma$ locally preserves randomness to find $q^+|\gamma \leq p^0|\gamma$. 

Next consider the case where \( Q^M_\gamma \) is non-trivial and \( \gamma \geq \gamma_0 + 1 \). Again work in \( V[H_\gamma] \). Let \( k^* \) be maximal with \( p^{k^*}_\gamma | \gamma \in H^M_\gamma \). (This \( k^* \) exists, since the sequence \((p^k)_{k \in \omega} \) was quick, so there is even a \( k \) with \( p^k_\gamma (\gamma_0 + 1) \notin H^M_{\gamma_0+1} \)) Consider \( Z \) as a \( Q^M_\gamma \)-name and (using (3.37)) find a quick interpretation \( Z' \) of \( Z \) witnessed by a sequence starting with \( p^{k^*}_\gamma (\gamma) \). In \( M[H^M_\alpha] \), \( Z' \) is now a \( P^M_\alpha / H^M_\alpha \)-name. Clearly, the sequence \((p^k_\gamma | \gamma)_{k \in \omega} \) is a quick sequence interpreting \( Z' \) as \( Z^* \). (Use the fact that \( p^k_\gamma \) forces \( k^* \geq k \).

Using the induction hypothesis, we can first extend \( q \) to a condition \( q' \in P_\gamma \) and then (again by our assumption that \( Q_\gamma \) locally preserves randomness) to a condition \( q^+ \in P_{\gamma+1} \).

**The nontrivial limit case:** \( M \cap \beta \) unbounded in \( \beta \), i.e., \( \delta' = \beta \). (This deals with cases (4) and (5) in Definition and Claim 3.21) In case (4) we have \( \beta \in M \), i.e., \( \beta = \delta \); in case (5) we have \( \beta \notin M \) and \( \beta < \delta \).

Let \( \alpha = \delta_0 < \delta_1 < \cdots \) be a sequence of \( M \)-ordinals cofinal in \( M \cap \delta' = M \cap \delta \). We may assume \( M \) that each \( Q^M_\delta \) is non-trivial.

Let \((Z_n)_{n \in \omega} \) be a list of all \( P^M_\delta \)-names in \( M \) of codes for null sets (starting with our given null set \( Z = Z_0 \)). Let \((E_n)_{n \in \omega} \) enumerate all open dense sets of \( P^M_\delta \) from \( M \). Without loss of generality we can assume that

\[
E_n \text{ decides } Z_0 | n, \ldots, Z_n | n.
\]

We write \( p^k_0 \) for \( p^k \), and \( Z_{0,0} \) for \( Z^* \); as mentioned above, \( Z = Z_0 \).

By induction on \( n \) we can now find a sequence \( \bar{p}_n = (p^k_0)_{k \in \omega} \) and \( P^M_\delta \)-names \( Z_{i,n} \) for \( i \in \{0, \ldots, n\} \) satisfying the following:

1. \( P^M_\delta \) forces that \( p^0_0 \leq p^{k-1}_n \) whenever \( p^{k-1}_n \in P^M_\delta / H^M_\delta \).
2. \( P^M_\delta \) forces that \( p^0_0 \in E_n \). (Clearly \( E_n \cap P^M_\delta / H^M_\delta \) is a dense set.)
3. \( \bar{p}_n \in M \) is a \( P^M_\delta \)-name for a quick sequence interpreting \((Z_0, \ldots, Z_n) \) as \((Z_{0,n}, \ldots, Z_{n,n}) \) (in \( P^M_\delta / H^M_\delta \)), so \( Z_{i,n} \) is a \( P^M_\delta \)-name of a code for a null set, for \( 0 \leq i \leq n \).

Note that this implies that the sequence \((p^{k-1}_n | \delta_n) \) is (forced to be) a quick sequence interpreting \((Z_{0,n}, \ldots, Z_{n-1,n}) \) as \((Z_{0,n-1}, \ldots, Z_{n-1,n-1}) \).

Using the induction hypothesis, we now define a sequence \((q_n)_{n \in \omega} \) of conditions \( q_n \in P_\delta \) and a sequence \((c_n)_{n \in \omega} \) (where \( c_n \) is a \( P^M_\delta \)-name) such that (for \( n > 0 \)) \( q_n \) extends \( q_{n-1} \) and forces the following:

- \( p^{0}_{n-1} \in H^M_\delta \).
- Therefore, \( p^0_0 \leq p^{0}_{n-1} \).
- \( r \) is random over \( M[H^M_\delta] \).
- Let \( c_n \) be the least \( c \) such that \( Z_{n,n} \subset c \).
- \( Z_{i,n} \subset c_i \), for \( i = 0, \ldots, n - 1 \).

Now let \( q = \bigcup_n q_n \in P^\text{CS}_{\delta'} \). As in Lemma 3.26 it is easy to see that \( q \in P^\text{gen}_{\delta'} \subseteq P_{\delta'} \). Moreover, by (3.39) we get that \( q \) forces that \( Z_i = \lim_n Z_{i,n} \). Since each set \( C_{c,r} := \{ x : x \subset c \} \) is closed, this implies that \( q \) forces \( Z_i \subset c_i \), in particular \( Z = Z_0 \subset c_0 \).

---

35 If for some \( \gamma \) all \( Q^M_\zeta \) with \( \zeta \geq \gamma \) are trivial, then \( P^M_\zeta = P^M_\gamma \), so by induction there is nothing to do. If \( Q^M_\zeta \) itself is trivial, then we let \( \delta_0 := \min \{ \zeta : Q^M_\zeta \text{ non-trivial} \} \) instead.

36 If we first enumerate a basis of the open sets instead of all of them...
The trivial cases: In all other cases, $M \cap \beta$ is bounded in $\beta$, so we have already dealt with everything at stage $\beta_0 := \sup(\beta \cap M)$. Note that $\delta_0$ and $\delta_0$ used at stage $\beta_0$ are the same as the current $\delta'$ and $\delta$.

4. The forcing construction

In this section we describe a $\sigma$-closed “preparatory” forcing notion $R$; the generic filter will define a “generic” forcing iteration $P$, so elements of $R$ will be approximations to such an iteration. In Section 5 we will show that the forcing $R \ast P_{\omega_2}$ forces BC and dBC.

From now on, we assume CH in the ground model.

4.A. Alternating iterations, canonical embeddings and the preparatory forcing $R$. The preparatory forcing $R$ will consist of pairs $(M, P)$, where $M$ is a countable model and $P \in M$ is an iteration of ultralaverg and Janus forcings.

Definition 4.1. An alternating iteration $^R$ is a topped partial CS iteration $P$ of length $\omega_2$ satisfying the following:

- Each $P_{\alpha}$ is proper $^38$
- For $\alpha$ even, either both $Q_{\alpha}$ and $Q_{\alpha+1}$ are (forced by the empty condition to be) trivial $^39$ or $P_{\alpha}$ forces that $Q_{\alpha}$ is an ultralaver forcing adding the generic real $\ell_{\alpha}$ and $P_{\alpha+1}$ forces that $Q_{\alpha+1}$ is a Janus forcing based on $\ell_{\alpha}$ (where $\ell^+$ is defined from $\ell$ as in Lemma 1.23).

We will call an even index an “ultralaver position” and an odd one a “Janus position”. As in any partial CS iteration, each $P_{\delta}$ for $\cf(\delta) > \omega$ (and in particular $P_{\omega_2}$) is a direct limit.

Recall that in Definition 3.10 we have defined the notion “$\bar{P} M$ canonically embeds into $\bar{P}^n$” for nice candidates $M$ and iterations $P \in V$ and $\bar{P} M \in M$. Since our iterations now have length $\omega_2$, this means that the canonical embedding works up to and including $\omega_2$. In the following, we will use pairs $x = (M^x, \bar{P}^x)$ as conditions in a forcing, where $\bar{P}^x$ is an alternating iteration in the nice candidate $M^x$. We will adapt our notation accordingly: Instead of writing $M, \bar{P} M, P_{\alpha}^M H_{\alpha}^M$ (the induced filter), $Q_{\alpha}^M$, etc., we will write $M^x, P^x, P_{\alpha}^x, H_{\alpha}^x, Q_{\alpha}^x$, etc. Instead of “$P^x$ canonically embeds into $\bar{P}$” we will say $^41$ “$x$ canonically embeds into $\bar{P}$” or “$(M^x, \bar{P}^x)$ canonically embeds into $\bar{P}$” (which is a more exact notation anyway, since the test for whether the embedding is $M^x$-complete uses both $M^x$ and $\bar{P}^x$, not just $P^x$).

The following rephrases Definition 3.10 of a canonical embedding in our new notation, taking into account that

\[ \mathbb{L}_{D^x} \text{ is an } M^x\text{-complete subforcing of } \mathbb{L}_D \iff \bar{D} \text{ extends } D^x \]

(see Lemma $^42$).

$^37$See Section 6 for possible variants of this definition.
$^38$This does not seem to be necessary; see Section 6 but it is easy to ensure and might be comforting to some of the readers and/or authors.
$^39$For definiteness, let us agree that the trivial forcing is the singleton $\{\emptyset\}$.
$^40$This is stronger than requiring that the canonical embedding works for every $\alpha \in \omega_2 \cap M$, even though both $P_{\omega_2}$ and $P_{M}^\omega$ are just direct limits; see footnote $^40$.
$^41$Note the linguistic asymmetry here: A symmetric and more verbose variant would say “$x = (M^x, \bar{P}^x)$ canonically embeds into $(V, P)$”. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Fact 4.2. $x = (M^x, \bar{P}^x)$ canonically embeds into $\bar{P}$ if (inductively) for all $\beta \in \omega_2 \cap M^x \cup \{\omega_2\}$ the following holds:

- Let $\beta = \alpha + 1$ for $\alpha$ even (i.e., an ultralaver position). Then either $Q^x_\alpha$ is trivial (and $Q_\alpha$ can be trivial or not) or we require that ($P_\alpha$ forces that) the $\nabla[H_\alpha]$-ultrafilter system $D$ used for $Q_\alpha$ extends the $M^x[H^x_\alpha]$-ultrafilter system $\bar{D}^x$ used for $Q^x_\alpha$.
- Let $\beta = \alpha + 1$ for $\alpha$ odd (i.e., a Janus position). Then either $Q^x_\alpha$ is trivial or we require that ($P_\alpha$ forces that) the Janus forcing $Q^x_\alpha$ is an $M^x[H^x_\alpha]$-complete subforcing of the Janus forcing $Q_\alpha$.
- Let $\beta$ be a limit. Then the canonical extension $i_\beta : P^x_\beta \rightarrow P_\beta$ is $M^x$-complete. (The canonical extension was defined in Definition 3.9)

Fix a sufficiently large regular cardinal $\chi^*$ (see Remark 3.3).

Definition 4.3. The “preparatory forcing” $\mathbb{R}$ consists of pairs $x = (M^x, \bar{P}^x)$ such that $M^x \in H(\chi^*)$ is a nice candidate (containing $\omega_2$), and $\bar{P}^x$ is in $M^x$ an alternating iteration (in particular, topped and of length $\omega_2$).

We define $y$ to be stronger than $x$ (in symbols $y \leq \mathbb{R} x$), if the following holds: either $x = y$ or:

- $M^x \in M^y$ and $M^x$ is countable in $M^y$.
- $M^y$ thinks that $(M^x, \bar{P}^x)$ canonically embeds into $\bar{P}^y$.

Note that this order on $\mathbb{R}$ is transitive.

We will sometimes write $i_{x,y}$ for the canonical embedding (in $M^y$) from $P^x_{\omega_2}$ to $P^y_{\omega_2}$.

There are several variants of this definition which result in equivalent forcing notions. We will briefly come back to this in Section 6.

The following is trivial by elementarity:

Fact 4.4. Assume that $\bar{P}$ is an alternating iteration (in $V$), that $x = (M^x, \bar{P}^x) \in \mathbb{R}$ canonically embeds into $\bar{P}$, and that $N \prec H(\chi^*)$ contains $x$ and $\bar{P}$. Let $y = (M^y, P^y)$ be the ord-collapse of $(N, \bar{P})$. Then $y \in \mathbb{R}$ and $y \leq x$.

This fact will be used, for example, to get from the following Lemma 4.5 to Corollary 4.6

Lemma 4.5. Given $x \in \mathbb{R}$, there is an alternating iteration $\bar{P}$ such that $x$ canonically embeds into $\bar{P}$.

Proof. For the proof, we use either of the partial CS constructions introduced in the previous chapter (i.e., an almost CS iteration or an almost FS iteration over $\bar{P}^x$). The only thing we have to check is that we can indeed choose $Q_\alpha$ that satisfy the definition of an alternating iteration (i.e., as ultralaver or Janus forcings) and such that $Q^x_\alpha$ is $M^x$-complete in $Q_\alpha$.

In the ultralaver case we arbitrarily extend $\bar{D}^x$ to an ultrafilter system $\bar{D}$, which is justified by Lemma 1.5.

In the Janus case, we take $Q_\alpha := Q^x_\alpha$ (this works by Fact 2.8). Alternatively, we could extend $Q^x_\alpha$ to a random forcing (using Lemma 2.20). □

Corollary 4.6. Given $x \in \mathbb{R}$ and an HCON object $b \in H(\chi^*)$ (e.g., a real or an ordinal), there is a $y \leq x$ such that $b \in M^y$.

What we will actually need are the following three variants:
Lemma 4.7.  

1. Given $x \in \mathbb{R}$ there is a $\sigma$-centered alternating iteration $\bar{P}$ above $x$.
2. Given a decreasing sequence $\bar{x} = (x_n)_{n \in \omega}$ in $\mathbb{R}$, there is an alternating iteration $\bar{P}$ such that each $x_n$ embeds into $\bar{P}$. Moreover, we can assume that for all Janus positions $\beta$, the Janus forcing $Q_\beta$ is (forced to be) the union of the $Q^x_{\beta} \alpha$, and that for all limits $\alpha$, the forcing $P_\alpha$ is the almost FS limit over $(x_n)_{n \in \omega}$ (as in Corollary 3.19).
3. Let $x, y \in \mathbb{R}$. Let $j^x$ be the transitive collapse of $M^x$, and define $j^y$ analogously. Assume that $j^x[M^x] = j^y[M^y]$, that $j^x(\bar{P}^x) = j^y(\bar{P}^y)$ and that there are $\alpha_0, \alpha_1 < \omega_2$ such that:
   - $M^x \cap \alpha_0 = M^y \cap \alpha_0$ (and thus $j^x|\alpha_0 = j^y|\alpha_0$).
   - $M^x \cap [\alpha_0, \omega_2) \subseteq [\alpha_0, \alpha_1)$.
   - $M^y \cap [\alpha_0, \omega_2) \subseteq [\alpha_1, \omega_2)$.

Then there is an alternating iteration $\bar{P}$ such that both $x$ and $y$ canonically embed into it.

Proof. For (1), use an almost FS iteration. We only use the coordinates in $M^x$ and use the (countable!) Janus forcings $Q_\alpha := Q^x_\alpha$ for all Janus positions $\alpha \in M^x$ (see Fact 2.8). Ultralaver forcings are $\sigma$-centered anyway, so $P_{\bar{x}}$ will be $\sigma$-centered by Lemma 3.17.

For (2), use the almost FS iteration over the sequence $(x_n)_{n \in \omega}$ as in Corollary 3.19 and at Janus positions $\alpha$ set $Q_\alpha$ to be the union of the $Q^x_{\alpha} \alpha_n$. (By Fact 2.8 $Q^x_{\alpha_n}$ is $M^x_{\alpha_n}$-complete in $Q_\alpha$, so Corollary 3.19 can be applied here.)

For (3), we again use an almost FS construction. This time we start with an almost FS construction over $x$ up to $\alpha_1$ and then continue with an almost FS construction over $y$. □

As above, Fact 4.4 gives us the following consequences:

Corollary 4.8.  

1. $\mathbb{R}$ is $\sigma$-closed. Hence $\mathbb{R}$ does not add new HCON objects (and in particular no new reals).
2. $\mathbb{R}$ forces that the generic filter $G \subseteq \mathbb{R}$ is $\sigma$-directed, i.e., for every countable subset $B$ of $G$ there is a $y \in G$ stronger than each element of $B$.
3. $\mathbb{R}$ forces CH. (Since we assume CH in $V Spear$)
4. Given a decreasing sequence $\bar{x} = (x_n)_{n \in \omega}$ in $\mathbb{R}$ and any HCON object $b \in H(\chi^*)$, there is a $y \in \mathbb{R}$ such that:
   - $y \leq x_n$ for all $n$.
   - $M^y$ contains $b$ and the sequence $\bar{x}$.
   - For all Janus positions $\beta$, $M^y$ thinks that the Janus forcing $Q^y_\beta$ is (forced to be) the union of the $Q^x_{\beta} \alpha_n$.
   - For all limits $\alpha$, $M^y$ thinks that $P^y_\alpha$ is the almost FS limit over $(x_n)_{n \in \omega}$ (of $P^y_\beta|\beta < \alpha$).

Proof. Item (1) directly follows from Lemma 4.7(2) and Fact 4.4. Item (1) is a special case of (1), and (2) and (3) are trivial consequences of (1). □

Another consequence of Lemma 4.7 is:

---

$^{42}$If all $Q^x_{\beta n}$ are trivial, then we may also set $Q$ to be the trivial forcing, which is formally not a Janus forcing.

$^{43}$Constructed in Lemma 3.19.
Lemma 4.9. The forcing notion $\mathbb{R}$ is $\aleph_2$-cc.

Proof. Recall that we assume that $V$ (and hence $V[G]$) satisfies CH.

Assume towards a contradiction that $(x_i : i < \omega_2)$ is an antichain. Using CH we may without loss of generality assume that for each $i \in \omega_2$ the transitive collapse of $(M^{x_i}, P^{x_i})$ is the same. Set $L_i := M^{x_i} \cap \omega_2$. Using the $\Delta$-lemma we find some uncountable $I \subseteq \omega_2$ such that the $L_i$ for $i \in I$ form a $\Delta$-system with root $L$. Set $\alpha_0 = \text{sup}(L) + 3$. Moreover, we may assume $\text{sup}(L_i) < \text{min}(L_j \setminus \alpha_0)$ for all $i < j$.

Now take any $i, j \in I$, set $x := x_i$ and $y := x_j$, and use Lemma 4.7(3). Finally, use Fact 4.4 to find $z \leq x_i, x_j$. \qed

4.B. The generic forcing $P'$. Let $G$ be $\mathbb{R}$-generic. Obviously $G$ is a $\leq_\mathbb{R}$-directed system. Using the canonical embeddings, we can construct in $V[G]$ a direct limit $P'_{\omega_2}$ of the directed system $G$: Formally, we set

$$P'_{\omega_2} := \{(x, p) : x \in G \text{ and } p \in P^x_{\omega_2}\}$$

and we set $(y, q) \leq (x, p)$ if $y \leq_\mathbb{R} x$ and $q$ is (in $y$) stronger than $i_{x,y}(p)$ (where $i_{x,y} : P^x_{\omega_2} \to P^y_{\omega_2}$ is the canonical embedding). Similarly, we define for each $\alpha$

$$P'_\alpha := \{(x, p) : x \in G, \alpha \in M^x \text{ and } p \in P^x_{\alpha}\}$$

with the same order.

To summarize:

Definition 4.10. For $\alpha \leq \omega_2$, the direct limit of the $P^x_{\alpha}$ with $x \in G$ is called $P'_\alpha$.

Formally, elements of $P'_{\omega_2}$ are defined as pairs $(x, p)$. However, the $x$ does not really contribute any information. In particular:

Fact 4.11. (1) Assume that $(x, p^x)$ and $(y, p^y)$ are in $P'_{\omega_2}$, that $y \leq x$, and that the canonical embedding $i_{x,y}$ witnessing $y \leq x$ maps $p^x$ to $p^y$. Then

$$(x, p^x) =^* (y, p^y).$$

(2) $(y, q)$ is in $P'_{\omega_2}$ stronger than $(x, p)$ iff for some (or equivalently for any) $z \leq x, y$ in $G$ the canonically embedded $q$ is in $P^z_{\omega_2}$ stronger than the canonically embedded $p$. The same holds if “stronger than” is replaced by “compatible with” or by “incompatible with”.

(3) If $(x, p) \in P'_\alpha$ and if $y$ is such that $M^y = M^x$ and $P^y|\alpha = P^x|\alpha$, then

$$(y, p) =^* (x, p).$$

In the following, we will therefore often abuse notation and just write $p$ instead of $(x, p)$ for an element of $P'_\alpha$.

We can define a natural restriction map from $P'_{\omega_2}$ to $P'_\alpha$ by mapping $(x, p)$ to $(x, p|\alpha)$. Note that by the fact above, we can assume without loss of generality that $\alpha \in M^x$. More exactly, there is a $y \leq x$ in $G$ such that $\alpha \in M^y$ (according to Corollary 4.13). Then in $P'_{\omega_2}$ we have $(x, p) =^* (y, p)$.

Fact 4.12. The following is forced by $\mathbb{R}$:

- $P'_\beta$ is completely embedded into $P'_\alpha$ for $\beta < \alpha \leq \omega_2$ (witnessed by the natural restriction map).
- If $x \in G$, then $P^x_{\alpha}$ is $M^x$-completely embedded into $P'_\alpha$ for $\alpha \leq \omega_2$ (by the identity map $p \mapsto (x, p)$).
- If $\text{cf}(\alpha) > \omega$, then $P'_\alpha$ is the union of the $P'_\beta$ for $\beta < \alpha$.
- By definition, $P'_{\omega_2}$ is a subset of $V$. 
$G$ will always denote an $\mathbb{R}$-generic filter, while the $P^{\omega_3}_\omega$-generic filter over $V[G]$ will be denoted by $H^{\omega_3}_\omega$ (and the induced $P^\omega_\alpha$-generic by $H^\alpha_\omega$). Recall that for each $x \in G$, the map $p \mapsto (x,p)$ is an $M^x$-complete embedding of $P^{\omega_3}_\omega$ into $P^{\omega_3}_\omega$ (and of $P^\omega_\alpha$ into $P^\omega_\alpha$). This way $H^\alpha'_\omega \subseteq P^\omega_\alpha$ induces an $M^x$-generic filter $H^\alpha_\omega \subseteq P^\omega_\alpha$.

So $x \in \mathbb{R}$ forces that $P^\alpha_\alpha$ is approximated by $P^\omega_\alpha$. In particular we get:

**Lemma 4.13.** Assume that $x \in \mathbb{R}$, that $\alpha \leq \omega_2$ in $M^x$, that $p \in P^\omega_\alpha$, that $\varphi(t)$ is a first order formula of the language $\{\in\}$ with one free variable $t$ and that $\hat{t}$ is a $P^\omega_\alpha$-name in $M^x$. Then $M^x \models p \Vdash P^\omega_\alpha \varphi(\hat{t})$ iff $x \Vdash R(x,p) \Vdash P^\omega_\alpha M^x[H^\alpha_\omega] \models \varphi(\hat{t}[H^\alpha_\omega])$.

**Proof.** “$\Rightarrow$” is clear. So assume that $\varphi(\hat{t})$ is not forced in $M^x$. Then some $q \leq P^\omega_\alpha p$ forces the negation. Now $x$ forces that $(x,q) \leq (x,p)$ in $P^\alpha_\alpha$, but the conditions $(x,q)$ and $(x,p)$ force contradictory statements. \hfill $\Box$

4.C. The inductive proof of $\text{ccc}$. We will now prove by induction on $\alpha$ that $P^\alpha_\alpha$ is (forced to be) $\text{ccc}$ and (equivalent to) an alternating iteration. Once we know this, we can prove Lemma 4.2, which easily implies all the lemmas in this section. So in particular these lemmas will only be needed to prove $\text{ccc}$ and not for anything else (and they will probably not aid in the understanding of the construction).

In this section, we try to stick to the following notation: $\mathbb{R}$-names are denoted with a tilde underneath (e.g., $\tilde{t}$), while $P^\omega_\alpha$-names or $P^\alpha_\alpha$-names (for any $\alpha \leq \omega_2$) are denoted with a dot accent (e.g., $\cdot t$). We use both accents when we deal with $\mathbb{R}$-names for $P^\alpha_\alpha$-names (e.g., $\cdot \hat{t}$).

We first prove a few lemmas that are easy generalizations of the following straightforward observation:

Assume that $x \Vdash R(z,p) \in P^\alpha_\alpha$. In particular, $x \Vdash z \in G$. We first strengthen $x$ to some $x_1$ that decides $z$ and $p$ to be $z^*$ and $p^*$. Then $x_1 \leq^* z^*$ (the order $\leq^*$ is defined on page 243), so we can further strengthen $x_1$ to some $y \leq z^*$. By definition, this means that $z^*$ is canonically embedded into $P^y$, so (by Fact 4.11) the $P^\omega_\alpha$-condition $p^*$ can be interpreted as a $P^y_\alpha$-condition as well. So we end up with some $y \leq x$ and a $P^y_\alpha$-condition $p^*$ such that $y \Vdash R(z,p) =^* (y,p^*)$.

Since $\mathbb{R}$ is $\sigma$-closed, we can immediately generalize this to countably many ($\mathbb{R}$-names for) $P^\alpha_\alpha$-conditions:

**Fact 4.14.** Assume that $x \Vdash R_p p_n \in P^\alpha_\alpha$ for all $n \in \omega$. Then there is a $y \leq x$ and there are $p_n^* \in P^y_\alpha$ such that $y \Vdash R_p p_n =^* p_n^*$ for all $n \in \omega$.

Recall that more formally we should write $x \Vdash R(\tilde{z},p_n) \in P^\alpha_\alpha$ and $y \Vdash R(\tilde{z},p_n) =^* (y,p^*_n)$.

We will need a variant of the previous fact:

**Lemma 4.15.** Assume that $P^\beta_\beta$ is forced to be $\text{ccc}$ and assume that $x$ forces (in $\mathbb{R}$) that $\tilde{t}_n$ is a $P^\beta_\beta$-name for a real (or an HCON object) for every $n \in \omega$. Then there is a $y \leq x$ and there are $P^\omega_\beta$-names $\tilde{t}_n^*$ in $M^y$ such that $y \Vdash R(\tilde{t}_n^*,p_n) =^* (y,p_n^*)$ for all $n$.

(Of course, we mean that $\tilde{t}_n$ is evaluated by $G * H^\beta_\beta$, while $\tilde{t}_n^*$ is evaluated by $H^\beta_\beta$.)

**Proof.** The proof is an obvious consequence of the previous fact, since the names of reals in a $\text{ccc}$ forcing can be viewed as countable sequences of conditions.

In more detail: For notational simplicity assume all $\tilde{t}_n$ are names for elements of $2^{\omega}$. Working in $V$, we can find for each $n,m \in \omega$ names for a maximal antichain
Lemma 4.16. (Same assumptions as in the previous lemma.) In $V[G][H^y_{\beta}]$, let $Q_{\beta}$ be the union of $Q^z_{\beta}[H^z_{\beta}]$ for all $z \in G$. In $V$, assume that $x$ forces that each $\tilde{r}_n$ is a name for an element of $Q_{\beta}$. Then there is a $y \leq x$ and there is in $M^y$ a sequence $(\hat{r}^*_n)_{n \in \omega}$ of $P^y_{\beta}$-names for elements of $Q^y_{\beta}$ such that $y$ forces $\tilde{r}_n = \hat{r}^*_n$ for all $n$.

Proof. Assume $x \in G$ and work in $V[G]$. Fix $n$. $P'_\beta$ forces that there is some $y_n \in G$ and some $P^y_{\beta}$-name $\tau_n \in M^{y_n}$ of an element of $Q^y_{\beta}$ such that $\tilde{r}_n$ (evaluated by $H^y_{\beta}$) is the same as $\tau_n$ (evaluated by $H^z_{\beta}$). Since we assume that $P'_\beta$ is ccc, we can find a countable set $Y_n \subseteq G$ of the possible $y_n$, i.e., the empty condition of $P'_\beta$ forces $y_n \in Y_n$. (As $\mathbb{R}$ is $\sigma$-closed and $Y_n \subseteq \mathbb{R} \subseteq V$, we must have $Y_n \in V$.)

So in $V$ there is (for each $n$) an $\mathbb{R}$-name $\hat{r}_n$ for this countable set. Since $\mathbb{R}$ is $\sigma$-closed, we can find some $z_0 \leq x$ deciding each $\hat{r}_n$ to be some countable set $Y^*_n \subseteq \mathbb{R}$. In particular, for each $y \in Y^*_n$ we know that $z_0 \Vdash_{\mathbb{R}} y \in G$, i.e., $z_0 \leq^* y$. So using once again that $\mathbb{R}$ is $\sigma$-closed we can find some $z$ stronger than $z_0$ and all the $y \in \bigcup_{n \in \omega} Y^*_n$. Let $X$ contain all $\tau \in M^y$ such that for some $y \in \bigcup_{n \in \omega} Y^*_n$, $\tau$ is a $P^y_{\beta}$-name for a $Q^y_{\beta}$-element. Since $z \leq y$, each $\tau \in X$ is actually $14$ a $P^y_{\beta}$-name for an element of $Q^z_{\beta}$.

So $X$ is a set of $P^y_{\beta}$-names for $Q^z_{\beta}$-elements; we can assume that $X \in M^x$. Also, $z$ forces that $\tilde{r}_n \in X$ for all $n$. Using Lemma 4.15, we can additionally assume that there is a $P^z_{\beta}$-name $\hat{r}^*_n$ in $M^z$ such that $z$ forces that $\tilde{r}_n = \hat{r}^*_n$ is forced for each $n$. By Lemma 4.13 we know that $M^z$ thinks that $P^z_{\beta}$ forces that $\hat{r}^*_n \in X$. Therefore $\hat{r}^*_n$ is a $P^z_{\beta}$-name for a $Q^z_{\beta}$-element.

We now prove by induction on $\alpha$ that $P'_\alpha$ is equivalent to a ccc alternating iteration:

Lemma 4.17. The following holds in $V[G]$ for $\alpha < \omega_2$:

---

44Here we use two consequences of $z \leq y$: Every $P^y_{\beta}$-name in $M^y$ can be canonically interpreted as a $P^z_{\beta}$-name in $M^z$, and $Q^y_{\beta}$ is (forced to be) a subset of $Q^z_{\beta}$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
(1) $P'_\alpha$ is equivalent to an alternating iteration. More formally, there is an iteration $(P_\beta, Q_\beta)_{\beta<\alpha}$ with limit $P_\alpha$ that satisfies the definition of alternating iteration (up to $\alpha$), and there is a naturally defined dense embedding $j_\alpha : P'_\alpha \to P_\alpha$ such that for $\beta < \alpha$ we have $j_\beta \subseteq j_\alpha$, and the embeddings commute with the restrictions. Each $Q_\alpha$ is the union of all $Q_\beta^x$ with $x \in G$. For $x \in G$ with $\alpha \in M^x$, the function $i_{x,\alpha} : P_\alpha^x \to P_\alpha$ that maps $p$ to $j_\alpha(x,p)$ is the canonical $\alpha$-complete embedding.

(2) In particular, a $P'_\alpha$-generic filter $H'_\alpha$ can be translated into a $P_\alpha$-generic filter that we call $H_\alpha$ (and vice versa).

(3) $P_\alpha$ has a dense subset of size $\aleph_1$.

(4) $P_\alpha$ is ccc.

(5) $P_\alpha$ forces CH.

Proof. $\alpha = 0$ is trivial (since $P_0$ and $P'_0$ are both trivial: $P_0$ is a singleton, and $P'_0$ consists of pairwise compatible elements).

So assume that all items hold for all $\beta < \alpha$.

Proof of (1).

**Ultralaver successor case:** Let $\alpha = \beta + 1$ with $\beta$ an ultralaver position. Let $H_\beta$ be $P_\beta$-generic over $V[G]$. Work in $V[G][H_\beta]$. By induction, for every $x \in G$ the canonical embedding $i_{x,\beta}$ defines a $P_\beta^x$-generic filter over $M^x$ called $H_\beta^x$.

**Definition of $Q_\beta$ (and thus of $P_\alpha$):** In $M^x[H_\beta^x]$, the forcing notion $Q_\beta^x$ is defined as $\mathbb{L}_{\beta^x}$ for some system of ultrafilters $D_\beta^x$ in $\mathcal{U}e_{\beta^x}$, the forcing notion $Q_\beta^x$ is defined as $\mathbb{L}_{\beta^x}$ for some system of ultrafilters $D_\beta^x$ in $\mathcal{U}e_{\beta^x}$.

Now work again in $V[G]$. We set $Q_\beta$ to be the $P_\beta$-name for $\mathbb{L}_D$. (Note that $P_\beta$ forces that $Q_\beta$ is literally the union of the $Q_\beta^x[H_\beta^x]$ for $x \in G$, again by Lemma 4.15.)

**Definition of $j_\alpha$:** Let $(x,p)$ be in $P'_\alpha$. If $p \in P_\beta^x$, then we set $j_\alpha(x,p) = j_\beta(x,p)$, i.e., $j_\alpha$ will extend $j_\beta$. If $p = (p|\beta \in \mathcal{P}_\alpha)$ is in $P_\alpha^x$ but not in $P_\beta^x$, we set $j_\alpha(x,p) = (r,s) \in P_\beta \ast Q_\beta$, where $r = j_\beta(x,p|\beta)$ and $s$ is the $P_\alpha$-name for $p(\beta)$ as evaluated in $M^x[H_\beta^x]$. From $Q_\beta = \bigcup_{x \in G} Q_\beta^x[H_\beta^x]$ we conclude that this embedding is dense.

The canonical embedding: By induction we know that $i_{x,\beta}$ which maps $p \in P_\beta^x$ to $j_\beta(x,p)$ (the restriction to $P_\beta^x$ of) the canonical embedding of $x$ into $P_\omega_2$. So we have to extend the canonical embedding to $i_{x,\alpha} : P_\alpha^x \to P_\alpha$. By definition of “canonical embedding”, $i_{x,\alpha}$ maps $p \in P_\alpha^x$ to the pair $(i_{x,\beta}(p|\beta), p(\beta))$. This is the same as $j_\alpha(x,p)$. We already know that $D_\alpha^x$ (forced to be) an $M^x[H_\beta^x]$-ultrafilter that is extended by $D_\alpha$.

**Janus successor case:** This is similar, but simpler than the previous case. Here, $Q_\beta$ is just defined as the union of all $Q_\beta^x[H_\beta^x]$ for $x \in G$. We will show below that this union satisfies the ccc. Just as in Fact 2.8 it is then easy to see that this union is again a Janus forcing.

\[45\text{i.e., } j_\beta(x,p|\beta) = j_\alpha(x,p|\beta) = j_\alpha(x,p)|\beta.\]
In particular, $Q_\beta$ consists of hereditarily countable objects (since it is the union of Janus forcings, which by definition consist of hereditarily countable objects). So since $P_\beta$ forces CH, $Q_\beta$ is forced to have size $\aleph_1$. Also note that since all Janus forcings involved are separative, the union (which is a limit of an incompatibility-preserving directed system) is trivially separative as well.

**Limit case:** Let $\alpha$ be a limit ordinal.

**Definition of $P_\alpha$ and $j_\alpha$:** First we define $j_\alpha : P_\alpha \to P_\alpha^{CS}$. For each $(x,p) \in P_\alpha$, let $j_\alpha(x,p) \in P_\alpha^{CS}$ be the union of all $j_\beta(x,p|\beta)$ (for $\beta \in (\alpha \cap M^x)$). (Note that $\beta_1 < \beta_2$ implies that $j_{\beta_1}(x,p|\beta_1)$ is a restriction of $j_{\beta_2}(x,p|\beta_2)$, so this union is indeed an element of $P_\alpha^{CS}$.)

$P_\alpha$ is the set of all $q \land p$, where $p \in j_\alpha[P_\alpha^\alpha]$, $q \in P_\beta$ for some $\beta < \alpha$, and $q \leq p|\beta$.

It is easy to check that $P_\alpha$ actually is a partial countable support limit and that $j_\alpha$ is dense. We will show below that $P_\alpha$ satisfies the ccc, so in particular it is proper.

**The canonical embedding:** To see that $i_{x,\alpha}$ is the (restriction of the) canonical embedding, we just have to check that it is $M^x$-complete. This is the case since $P_\alpha'$ is the direct limit of all $P_\alpha^y$ for $y \in G$ (without loss of generality $y \leq x$) and each $i_{x,y}$ is $M^x$-complete (see Fact 4.12).

**Proof of (3).**

Recall that we assume CH in the ground model.

The successor case, $\alpha = \beta + 1$, follows easily from (3)–(5) for $P_\beta$ (since $P_\beta$ forces that $Q_\beta$ has size $2^{\aleph_0} = \aleph_1$).

If $cf(\alpha) > \omega$, then $P_\alpha = \bigcup_{\beta < \alpha} P_\beta$, so the proof is easy.

So let $cf(\alpha) = \omega$. The following straightforward argument works for any ccc partial CS iteration where all iterands $Q_\beta$ are of size $\leq \aleph_1$.

For notational simplicity we assume $\forces_{P_\beta} Q_\beta \subseteq \omega_1$ for all $\beta < \alpha$ (this is justified by inductive assumption (4)). By induction, we can assume that for all $\beta < \alpha$ there is a dense $P_\beta^* \subseteq P_\beta$ of size $\aleph_1$ and that every $P_\beta^*$ is ccc. For each $p \in P_\alpha$ and all $\beta \in \text{dom}(p)$ we can find a maximal antichain $A_\beta^p \subseteq P_\beta^*$ such that each element $a \in A_\beta^p$ decides the value of $p(\beta)$, say $a \forces_{P_\beta^*} p(\beta) = \gamma_\beta^p(a)$. Writing $\overset{\rightarrow}{\sim}$ to $p \sim q$ if $p \leq q$ and $q \leq p$, the map $p \mapsto (A_\beta^p, \gamma_\beta^p)_{\beta \in \text{dom}(p)}$ is 1-1 modulo $\sim$. Since each $A_\beta^p$ is countable, there are only $\aleph_1$ many possible values, therefore there are only $\aleph_1$ many $\sim$-equivalence classes. Any set of representatives will be dense.

Alternatively, we can prove (3) directly for $P_\alpha'$. I.e., we can find a $\preceq^{*}$-dense subset $P'' \subseteq P_\alpha'$ of cardinality $\aleph_1$. Note that a condition $(x,p) \in P_\alpha'$ essentially depends only on $p$ (cf. Fact 4.11). More specifically, given $(x,p)$ we can “transitively” collapse $x$ above $\alpha^*$, resulting in a $=^*$-equivalent condition $(x',p')$. Since $|\alpha| = \aleph_1$, there are only $\aleph_1^{\aleph_0} = 2^{\aleph_0}$ many such candidates $x'$, and since each $x'$ is countable and $p' \in x'$, there are only $2^{\aleph_0}$ many pairs $(x',p')$.

---

46Since $\preceq$ is separative, $p \sim q$ iff $p =^* q$, but this fact is not used here.

47In more detail: We define a function $f : M^x \to V$ by induction as follows. If $\beta \in M^x \cap \alpha + 1$ or if $\beta = \omega_2$, then $f(\beta) = \beta$. Otherwise, if $\beta \in M^x \cap \text{Ord}$, then $f(\beta)$ is the smallest ordinal above $f(\beta)$. If $a \in M^x \setminus \text{Ord}$, then $f(a) = \{ f(b) : b \in a \cap M^x \}$. It is easy to see that $f$ is an isomorphism from $M^x$ to $M^{x'} := f[M^x]$ and that $M^{x'}$ is a candidate. Moreover, the ordinals that occur in $M^{x'}$ are subsets of $\alpha + \omega_1$ together with the interval $[\omega_2, \omega_2 + \omega_1]$; i.e., there are $\aleph_1$ many ordinals that can possibly occur in $M^{x'}$, and therefore there are $2^{\aleph_0}$ many possible such candidates. Moreover, setting $p' := f(p)$, it is easy to check that $(x,p) =^* (x',p')$ (similar to Fact 4.11).
Proof of (1).

Ultralaver successor case: Let \( \alpha = \beta + 1 \) with \( \beta \) an ultralaver position. We already know that \( P_\alpha = P_\beta \ast Q_\beta \), where \( Q_\beta \) is an ultralaver forcing, which in particular is ccc, so by induction \( P_\alpha \) is ccc.

Janus successor case: As above it suffices to show that \( Q_\beta \), the union of the Janus forcings \( Q_\beta^x[H_\beta^x] \) for \( x \in G \), is (forced to be) ccc.

Assume towards a contradiction that this is not the case, i.e., that we have an uncountable antichain in \( Q_\beta \). We already know that \( Q_\beta \) has size \( \aleph_1 \) and therefore the uncountable antichain has size \( \aleph_1 \). So, working in \( V \), we assume towards a contradiction that

\[
(4.18) \quad x_0 \models_p p_0 \models_{P_\beta} \{ \dot{a}_i : i \in \omega_1 \} \text{ is a maximal (uncountable) antichain in } Q_\beta.
\]

We construct by induction on \( n \in \omega \) a decreasing sequence of conditions such that \( x_{n+1} \) satisfies the following:

(i) For all \( i \in \omega_1 \cap M^{x_n} \) there is (in \( M^{x_{n+1}} \)) a \( P_\beta^{x_{n+1}} \)-name \( \dot{a}_i^* \) for a \( Q_\beta^{x_{n+1}} \)-condition such that

\[
x_{n+1} \models_p p_0 \models_{P_\beta} \dot{a}_i = \dot{a}_i^*.
\]

How can we get that? Just use Lemma 4.16.

(ii) If \( \tau \) is in \( M^{x_n} \) a \( P_\beta^{x_n} \)-name for an element of \( Q_\beta^{x_n} \), then there is \( k^*(\tau) \in \omega_1 \) such that

\[
x_{n+1} \models_p p_0 \models_{P_\beta} (\exists i < k^*(\tau)) \dot{a}_i \parallel P_\beta \tau.
\]

Also, all these \( k^*(\tau) \) are in \( M^{x_{n+1}} \).

How can we get that? First note that \( x_n \models p_0 \models (\exists i \in \omega_1) \dot{a}_i \parallel \tau \). Since \( P_\beta \) is ccc, \( x_n \) forces that there is some bound \( k(\tau) \) for \( i \). So it suffices that \( x_{n+1} \) determines \( k(\tau) \) to be \( k^*(\tau) \) (for all the countably many \( \tau \)).

Set \( \delta^* := \omega_1 \cap \bigcup_{n \in \omega} M^{x_n} \). By Corollary 4.8(1), there is some \( y \) such that

- \( y \leq x_n \) for all \( n \in \omega \),
- \( (x_n)_{n \in \omega} \) and \( (\dot{a}_i^*)_{i \in \delta^*} \) are in \( M^y \),
- \( (M^y \text{ thinks that}) P_\beta^y \text{ forces that } Q_\beta^y \text{ is the union of } Q_\beta^{x_n} \), i.e., as a formula, \( M^y \models P_\beta^y \models Q_\beta^y = \bigcup_{n \in \omega} Q_\beta^{x_n} \).

Let \( G \) be \( \mathbb{R} \)-generic (over \( V \)) containing \( y \), and let \( H_\beta \) be \( P_\beta \)-generic (over \( V[G] \)) containing \( p_0 \).

Set \( A^* := \{ \dot{a}_i^*[H_\beta^y] : i < \delta^* \} \). Note that \( A^* \) is in \( M^y[H_\beta^y] \). We claim

\[
(4.19) \quad A^* \subseteq Q_\beta^y[H_\beta^y] \text{ is predense}.
\]

Pick any \( q_0 \in Q_\beta^y \). So there is some \( n \in \omega \) and some \( \tau \) which is in \( M^{x_n} \) a \( P_\beta^{x_n} \)-name of a \( Q_\beta^{x_n} \)-condition such that \( q_0 = \tau[H_\beta^{x_n}] \). By (ii) above, \( x_{n+1} \), and therefore \( y \), forces (in \( \mathbb{R} \)) that for some \( i < k^*(\tau) \) (and therefore some \( i < \delta^* \)) the condition \( p_0 \) forces the following (in \( P_\beta \)):

The conditions \( \dot{a}_i \) and \( \tau \) are compatible in \( Q_\beta \). Also, \( \dot{a}_i = \dot{a}_i^* \) and \( \tau \) are both in \( Q_\beta^y \), and \( Q_\beta^y \) is an incompatibility-preserving subforcing of \( Q_\beta \). Therefore \( M^y[H_\beta^y] \) thinks that \( \dot{a}_i^* \) and \( \tau \) are compatible.

This proves (4.19).

Since \( Q_\beta^y[H_\beta^y] \) is \( M^y[H_\beta^y] \)-complete in \( Q_\beta[H_\beta] \) and since \( A^* \in M^y[H_\beta^y] \), this implies (as \( \dot{a}_i^*[H_\beta^y] = \dot{a}_i[G \ast H_\beta] \) for all \( i < \delta^* \)) that \( \{ \dot{a}_i[G \ast H_\beta] : i < \delta^* \} \) is already predense, a contradiction to (4.18).

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
**Limit case:** We work with $P'_{\alpha}$, which by definition only contains HCON objects.

Assume towards a contradiction that $P'_{\alpha}$ has an uncountable antichain. We already know that $P'_{\alpha}$ has a dense subset of size $\aleph_1$ (modulo $=^*$), so the antichain has size $\aleph_1$.

Again, work in $V$. We assume towards a contradiction that

$$x_0 \models \{a_i : i \in \omega_1\} \text{ is a maximal (uncountable) antichain in } P'_{\alpha}.$$ 

So each $a_i$ is an $\mathbb{R}$-name for an HCON object $(x, p)$ in $V$.

To lighten the notation we will abbreviate elements $(x, p) \in P'_{\alpha}$ by $p$; this is justified by Fact 4.11.

Fix any HCON object $p$ and $\beta < \alpha$. We will now define the $(\mathbb{R} \ast P'_{\beta})$-names $\hat{i}(\beta, p)$ and $\hat{r}(\beta, p)$. Let $G$ be $\mathbb{R}$-generic and containing $x_0$, and $H'_{\beta}$ be $P'_{\beta}$-generic. Let $R$ be the quotient $P'_{\alpha}/H'_{\beta}$. If $p$ is not in $R$, set $\hat{i}(\beta, p) = \hat{r}(\beta, p) = 0$. Otherwise, let $\hat{i}(\beta, p)$ be the minimal $i$ such that $a_i \in R$ and $a_i$ and $p$ are compatible (in $R$), and set $\hat{r}(\beta, p) \in R$ to be a witness of this compatibility. Since $P'_{\beta}$ is (forced to be) ccc, we can find (in $V[G]$) a countable set $X'(\beta, p) \subseteq \omega_1$ containing all possibilities for $\hat{i}(\beta, p)$ and similarly $X''(\beta, p)$ consisting of HCON objects for $\hat{r}(\beta, p)$.

To summarize: For every $\beta < \alpha$ and every HCON object $p$, we can define (in $V$) the $\mathbb{R}$-names $X'(\beta, p)$ and $X''(\beta, p)$ such that

$$(4.21) \quad x_0 \models \mathbb{R} \models P'_{\beta} \left( p \in P'_{\alpha}/H'_{\beta} \rightarrow (\exists i \in X'(\beta, p)) \right. (\exists r \in X''(\beta, p)) \left. \quad r \leq P'_{\alpha}/H'_{\beta}, p, a_i \right).$$

Similarly to the Janus successor case, we define by induction on $n \in \omega$ a decreasing sequence of conditions such that $x_{n+1}$ satisfies the following. For all $\beta \in \alpha \cap M^{x_n}$ and $p \in P'_{\alpha}$, $x_{n+1}$ decides $X'(\beta, p)$ and $X''(\beta, p)$ to be some $X^{x_*}(\beta, p)$ and $X''^{x_*}(\beta, p)$. For all $i \in \omega_1 \cap M^{x_n}$, $x_{n+1}$ decides $a_i$ to be some $a_i^* \in P'_{\alpha}$.

Moreover, each such $X^{x_*}$ and $X''^{x_*}$ is in $M^{x_{n+1}}$, and every $r \in X''^{x_*}(\beta, p)$ is in $P'_{\alpha}$.

(For this, we just use Fact 4.14 and Lemma 4.15.)

Set $\delta^* := \omega_1 \cap \bigcup_{n \in \omega} M^{x_n}$ and set $A^* := \{a_i^* : i \in \delta^*\}$. By Corollary 4.18, there is some $y$ such that

$$(4.22) \quad y \leq x_n \text{ for all } n \in \omega,$$

$$(4.23) \quad \bar{x} := (x_n)_{n \in \omega} \text{ and } A^* \text{ are in } M^y,$$

$$(4.24) \quad (M^y \text{ thinks that }) P^y_{\alpha} \text{ is defined as the almost FS limit over } \bar{x}.$$  

We claim that $y$ forces

$$x_0 \models \{a_i : i \in \delta^*\} \text{ is predense in } P^y_{\alpha}.$$  

Since $P^y_{\alpha}$ is $M^y$-completely embedded into $P'_{\alpha}$, and since $A^* \in M^y$ (and since $a_i = a_i^*$ for all $i \in \delta^*$), we get that $\{a_i : i \in \delta^*\}$ is predense, a contradiction to (4.20).

So it remains to show (4.25). Let $G$ be $\mathbb{R}$-generic containing $y$. Let $r$ be a condition in $P^y_{\alpha}$; we will find $i < \delta^*$ such that $r$ is compatible with $a_i^*$. Since $P^y_{\alpha}$ is the almost FS limit over $\bar{x}$, there is some $n \in \omega$ and $\beta \in \alpha \cap M^{x_n}$ such that $r$ has the form $q \wedge p$ with $p$ in $P'_{\alpha}$, $q \in P^y_{\beta}$ and $q \leq p|\beta$.

Now let $H'_\beta$ be $P'_{\beta}$-generic containing $q$. Work in $V[G][H'_\beta]$. Since $q \leq p|\beta$, we get $p \in P'_{\alpha}/H'_\beta$. Let $\bar{r}^*$ be the evaluation by $G \ast H'_\beta$ of $\hat{r}(\beta, p)$, and let $r^*$ be the evaluation of $\hat{r}(\beta, p)$. Note that $\bar{r}^* < \delta^*$ and $r^* \in P^y_{\alpha}$. So we know that $a_i^*$ and $p$
are compatible in $\mathbb{P}_\alpha /H^+_\beta$ witnessed by $r^*$. Find $q' \in H^+_\beta$ forcing $r^* \leq P^*_\alpha /H^+_\beta P, a^*_\alpha$. We may find $q' \leq q$. Now $q' \wedge r^*$ witnesses that $q \wedge p$ and $a^*_\alpha$ are compatible in $P^*_\alpha$.

To summarize, the crucial point in proving the ccc is that “densely” we choose (a variant of) a countable support iteration; see [4, 23]. Still, it is a bit surprising that we get the ccc, since we can also argue that densely we use (a variant of) a countable support iteration. But this does not prevent the ccc, it only prevents the generic iteration from having direct limits in stages of countable cofinality.

Proof of (5).

This follows from [3] and [1].

4.D. The generic alternating iteration $\mathbb{P}$. In Lemma [4.17] we have seen:

Corollary 4.26. Let $G$ be $\mathbb{R}$-generic. Then we can construct $\bar{\mathbb{P}}$ (in $V[G]$) an alternating iteration $\mathbb{P}$ such that the following holds:

- $\mathbb{P}$ is ccc.
- If $x \in G$, then $x$ canonically embeds into $\bar{\mathbb{P}}$. (In particular, a $\mathbb{P}_{\omega_2}$-generic filter $H_{\omega_2}$ induces a $P^x_{\omega_2}$-generic filter over $M^2$, called $H^x_{\omega_2}$.)
- Each $Q_\alpha$ is the union of all $Q^\alpha_\beta[H^x_\alpha]$ with $x \in G$.
- $\mathbb{P}_{\omega_2}$ is equivalent to the direct limit $\mathbb{P}'_{\omega_2}$ of $G$: There is a dense embedding $j : \mathbb{P}'_{\omega_2} \to \mathbb{P}_{\omega_2}$, and for each $x \in G$ the function $p \mapsto j(x, p)$ is the canonical embedding.

Lemma 4.27. Let $x \in \mathbb{R}$. Then $\mathbb{R}$ forces the following: $x \in G$ iff $x$ canonically embeds into $\bar{\mathbb{P}}$.

Proof. If $x \in G$, then we already know that $x$ canonically embeds into $\bar{\mathbb{P}}$.

So assume (towards a contradiction) that $y$ forces that $x$ embeds, but $y \not\models x \notin G$. Work in $V[G]$, where $y \in G$. Both $x$ (by assumption) and $y \in G$ canonically embed into $\bar{\mathbb{P}}$. Let $N$ be an elementary submodel of $H^{V[G]}(\chi^*)$ containing $x, y, \bar{\mathbb{P}}$, and let $z = (M^x, \bar{\mathbb{P}}^x)$ be the ord-collapse of $(N, \bar{\mathbb{P}})$. Then $z \in V$ (as $\mathbb{R}$ is $\sigma$-closed) and $z \in \mathbb{R}$, and (by elementarity) $z \leq x, y$. This shows that $x \not\models y$, i.e., $y$ cannot force $x \notin G$, a contradiction.

Using ccc, we can now prove a lemma that is in fact stronger than the lemmas in the previous Section 4.C:

Lemma 4.28. The following is forced by $\mathbb{R}$: Let $N \prec H^{V[G]}(\chi^*)$ be countable, and let $y$ be the ord-collapse of $(N, \bar{\mathbb{P}})$. Then $y \in G$. Moreover, if $x \in G \cap N$, then $y \leq x$.

Proof. Work in $V[G]$ with $x \in G$. Pick an elementary submodel $N$ containing $x$ and $\bar{\mathbb{P}}$. Let $y$ be the ord-collapse of $(N, \bar{\mathbb{P}})$ via a collapsing map $k$. As above, it is clear that $y \in \mathbb{R}$ and $y \leq x$. To show $y \in G$, it is (by the previous lemma) enough to show that $y$ canonically embeds. We claim that $k^{-1}$ is the canonical embedding of $y$ into $\bar{\mathbb{P}}$. The crucial point is to show $M^y$-completeness. Let $B \in M^y$ be a

---

48Assume that $x$ forces that $P^\alpha_\beta$ is the union of the $P^\alpha_\beta$ for $\beta < \alpha$. Then we can find a stronger $y$ that uses an almost CS iteration over $x$. This almost CS iteration contains a condition $p$ with unbounded support. (Take any condition in the generic part of the almost CS limit. If this condition has a bounded domain, we can extend it to have an unbounded domain; see Definition and Claim [4.21].) Now $p$ will be in $P^\alpha_\beta$ and have an unbounded domain.

49In an “absolute way”: Given $G$, we first define $P_{\omega_2}$ to be the direct limit of $G$ and then inductively construct the $P_\alpha$’s from $P_{\omega_2}$.
maximal antichain of $P^y_{\omega_2}$, say $B = k(A)$ where $A \in N$ is a maximal antichain of $P_{\omega_2}$. So (by ccc) $A$ is countable, and hence $A \subseteq N$. So not only $A = k^{-1}(B)$ but even $A = k^{-1}[B]$. Hence $k^{-1}$ is an $M^y$-complete embedding. □

Remark 4.29. We used the ccc of $P_{\omega_2}$ to prove Lemma 4.28. This use was essential in the sense that we could in turn easily prove the ccc of $P_{\omega_2}$ if we assumed that Lemma 4.28 holds. In fact Lemma 4.28 easily implies all other lemmas in Section 4.C as well.

5. The proof of BC+dBC

We first prove that no uncountable $X$ in $V$ will be smz or sm in the final extension $V[G * H]$. Then we show how to modify the argument to work for all uncountable sets in $V[G * H]$.

5.A. BC+dBC for ground model sets.

Lemma 5.1. Let $X \in V$ be an uncountable set of reals. Then $R * P_{\omega_2}$ forces that $X$ is not smz.

Proof.

1. Fix any even $\alpha < \omega_2$ (i.e., an ultralaver position) in our iteration. The ultralaver forcing $Q_\alpha$ adds a (canonically defined code for $a$) closed null set $\dot{F}$ constructed from the ultralaver real $\bar{\ell}_\alpha$. (Recall Corollary 1.21.)

2. According to Theorem 0.2 it is enough to show that $X + \dot{F}$ is non-null in the $R * P_{\omega_2}$-extension or, equivalently, in every $R * P_\beta$-extension ($\alpha < \beta < \omega_2$). So assume towards a contradiction that there is a $\beta > \alpha$ and an $R * P_\beta$-name $\dot{Z}$ of a (code for $a$) Borel null set such that some $(x, p) \in R * P_{\omega_2}$ forces that $X + \dot{F} \subseteq \dot{Z}$.

3. Using the dense embedding $j_{\omega_2} : P'_{\omega_2} \rightarrow P_{\omega_2}$, we may replace $(x, p)$ by a condition $(x, p') \in R * P'_{\omega_2}$. According to Fact 4.14 (recall that we now know that $P_{\omega_2}$ satisfies ccc) and Lemma 4.15 we can assume that $p'$ is already a $P_\beta$-condition $p^x$ and that $\dot{Z}$ is (forced by $x$ to be the same as) a $P_\beta$-name $\dot{Z}^x$ in $M^x$.

4. We construct (in $V$) an iteration $\bar{P}$ in the following way:

   a. Up to $\alpha$, we take an arbitrary alternating iteration into which $x$ embeds. In particular, $P_\alpha$ will be proper and hence force that $X$ is still uncountable.

   b. Let $Q_\alpha$ be any ultralaver forcing (over $Q_\alpha^x$ in case $\alpha \in M^x$). So according to Corollary 1.21 we know that $Q_\alpha$ forces that $X + \dot{F}$ is not null.

Therefore we can pick (in $V[H_{\alpha+1}]$) some $\hat{r}$ in $X + \dot{F}$ which is random over (the countable model) $M^x[H_{\alpha+1}^x]$, where $H_{\alpha+1}^x$ is induced by $H_{\alpha+1}$.

50Note that for this weak version, it would be enough to produce a generic iteration of length 2 only, i.e., $Q_0 * Q_1$, where $Q_0$ is an ultralaver forcing and $Q_1$ a corresponding Janus forcing.
(c) In the rest of the construction, we preserve randomness of \( \hat{r} \) over \( M^x[H^x_\alpha] \) for each \( \zeta \leq \omega_2 \). We can do this using an almost CS iteration over \( x \), where at each Janus position we use a random version of Janus forcing and at each ultralaver position we use a suitable ultralaver forcing; this is possible by Lemma 3.32. By Lemma 3.34, this iteration will preserve the randomness of \( \hat{r} \).

(4) So we get \( \hat{P} \) over \( x \) (with canonical embedding \( i_x \)) and \( q \leq_{P_{\omega_2}} i_x(p^x) \) such that \( q|_{\beta} \) forces (in \( P_{\beta} \)) that \( \hat{r} \) is random over \( M^x[H^x_\beta] \); in particular, that \( \hat{r} \notin \hat{Z}^x \).

We now pick a countable \( N < H(\check{x}^*) \) containing everything and ord-collapse \( (N, \hat{P}) \) to \( y \leq x \). (See Fact 4.4.) Set \( X^y := X \cap M^y \) (the image of \( X \) under the collapse). By elementarity, \( M^y \) thinks that (a)–(d) above holds for \( P^y \) and that \( X^y \) is uncountable. Note that \( X^y \subseteq X \).

(5) This gives a contradiction in the obvious way: Let \( G \) be \( \mathbb{R} \)-generic over \( V \) and contain \( y \), and let \( H_\beta \) be \( P_\beta \)-generic over \( V[G] \) and contain \( q|_{\beta} \). So \( M^y[H^y_\beta] \) thinks that \( r \notin \hat{Z}^y \) (which is absolute) and that \( r = x + f \) for some \( x \in X^y \subseteq X \) and \( f \in F \) (actually even in \( F \) as evaluated in \( M^y[H^y_{\alpha+1}] \)). So in \( V[G][H_\beta] \), \( r \) is the sum of an element of \( X \) and an element of \( F \). So \( (y, q) \leq (x, p^x) \) forces that \( \hat{r} \in (X + \hat{F}) \setminus \hat{Z} \), a contradiction to (2). \( \square \)

Of course, we need this result not just for ground model sets \( X \), but for \( \mathbb{R} * P_{\omega_2} \)-names \( \check{X} = (\check{x}_i : i \in \omega_1) \) of uncountable sets. It is easy to see that it is enough to deal with \( \mathbb{R} * P_\beta \)-names for (all) \( \beta < \omega_2 \). So given \( \check{X} \), we can (in the proof) pick \( \alpha \) such that \( \check{X} \) is actually an \( \mathbb{R} * P_\alpha \)-name. We can try to repeat the same proof; however, the problem is the following. When constructing \( \check{P} \) in (4), it is not clear how to simultaneously make all the uncountably many names \( (\check{x}_i) \) into \( \check{P} \)-names in a sufficiently “absolute” way. In other words, it is not clear how to end up with some \( M^y \) and \( \check{X} \) uncountable in \( M^y \) such that it is guaranteed that \( \check{X}^y \) (evaluated in \( M^y[H^y_{\alpha}] \)) will be a subset of \( \check{X} \) (evaluated in \( V[G][H_\alpha] \)). We will solve this problem in the next section by factoring \( \mathbb{R} \).

Let us now give the proof of the corresponding weak version of dBC:

**Lemma 5.2.** Let \( X \in V \) be an uncountable set of reals. Then \( \mathbb{R} * P_{\omega_2} \) forces that \( X \) is not strongly meager.

**Proof.** The proof is parallel to the previous one:

1. **Fix any even \( \alpha < \omega_2 \) (i.e., an ultralaver position) in our iteration. The Janus forcing \( Q_{\alpha+1} \) adds a (canonically defined code for \( a \)) null set \( \check{Z}_\neg \).** (See Definition 2.7 and Fact 2.7)

2. According to (1), it is enough to show that \( X + \check{Z}_\neg = 2^\omega \) in the \( \mathbb{R} * P_{\omega_2} \)-extension or, equivalently, in every \( \mathbb{R} * P_\beta \)-extension (\( \alpha < \beta < \omega_2 \)). (For every real \( r \), the statement \( r \in X + \check{Z}_\neg \), i.e., \( (\exists x \in X) x + r \in \check{Z}_\neg \), is absolute.) So assume towards a contradiction that there is a \( \beta > \alpha \) and an \( \mathbb{R} * P_\beta \)-name \( \check{r} \) of a real such that some \( (x, p) \in \mathbb{R} * P_{\omega_2} \) forces that \( \check{r} \notin X + \check{Z}_\neg \).

3. Again, we can assume that \( \check{r} \) is a \( P^x_\beta \)-name \( \check{r}^x \) in \( M^x \).

4. We construct (in \( V \)) an iteration \( \check{P} \) in the following way:

   a. **Up to \( \alpha \), we take an arbitrary alternating iteration into which \( x \) embeds. In particular, \( P_\alpha \) again forces that \( X \) is still uncountable.**
(b1) Let $Q_\alpha$ be any ultralaver forcing (over $Q_\alpha^\alpha$). Then $Q_\alpha$ forces that $X$ is not thin (see Corollary 1.22).

(b2) Let $Q_{\alpha+1}$ be a countable Janus forcing. So $Q_{\alpha+1}$ forces $X + \check{Z}_\forall = 2^\omega$. (See Lemma 2.21)

(c) We continue the iteration in a $\sigma$-centered way. I.e., we use an almost FS iteration over $x$ of ultralaver forcings and countable Janus forcings, using trivial $Q_\zeta$ for all $\zeta \notin M^x$; see Lemma 3.17.

(d) So $P_\beta$ still forces that $X + \check{Z}_\forall = 2^\omega$, and in particular that $r^z \in X + \check{Z}_\forall$. (Again by Lemma 2.9)

Again, by collapsing some $N$ as in the previous proof, we get $y \leq x$ and $X^y \subseteq X$.

(5) This again gives the obvious contradiction: Let $G$ be $R$-generic over $V$ and contain $y$, and let $H_\beta$ be $P_\beta$-generic over $V[G]$ and contain $p$. So $\check{M}^y[H_\beta^y]$ thinks that $r = x + z$ for some $x \in X^y \subseteq X$ and $z \in Z_\forall$ (this time, $\check{Z}_\forall$ is evaluated in $M^y[H_\beta^y]$), contradicting (2). □

5.B. A factor lemma. We can restrict $R$ to any $\alpha^* < \omega_2$ in the obvious way: Conditions are pairs $x = (M^x, \check{P}^x)$ of nice candidates $M^x$ (containing $\alpha^*$) and alternating iterations $\check{P}^x$, but now $M^x$ thinks that $\check{P}^x$ has length $\alpha^*$ (and not $\omega_2$). We call this variant $R[\alpha^*].$

Note that all results of Section 4 about $R$ are still true for $R[\alpha^*]$. In particular, whenever $G \subseteq R[\alpha^*]$ is generic, it will define a direct limit (which we call $P[\alpha^*]$) and an alternating iteration of length $\alpha^*$ (called $P^*$); again we will have that $x \in G$ iff $x$ canonically embeds into $P^*$.

There is a natural projection map from $R$ (more exactly, from the dense subset of those $x$ which satisfy $\alpha^* \in M^x$) into $R[\alpha^*]$, mapping $x = (M^x, \check{P}^x)$ to $x[\alpha^*] := (M^x, \check{P}^x[\alpha^*])$. (It is obvious that this projection is dense and preserves $\leq$.)

There is also a natural embedding $\varphi$ from $R[\alpha^*]$ to $R$: We can just continue an alternating iteration of length $\alpha^*$ by appending trivial forcings.

$\varphi$ is complete: It preserves $\leq$ and $\perp$. (Assume that $z \leq \varphi(x), \varphi(y)$. Then $z[\alpha^*] \leq x, y.$) Also, the projection is a reduction: If $y \leq x[\alpha^*]$ in $R[\alpha^*]$, then let $M^z$ be a model containing both $x$ and $y$. In $M^z$, we can first construct an alternating iteration of length $\alpha^*$ over $y$ (using almost FS over $y$ or almost CS — this does not matter here). We then continue this iteration $\check{P}^z$ using almost FS or almost CS over $x$. So $x$ and $y$ both embed into $\check{P}^z$, hence $z = (M^z, \check{P}^z) \leq x, y$.

So according to the general factor lemma of forcing theory, we know that $R$ is forcing equivalent to $R[\alpha^*] R[\alpha^*] (R/R[\alpha^*])$, where $R/R[\alpha^*]$ is the quotient of $R$ and $R[\alpha^*$, i.e., the $(R[\alpha^*]$-name for the) set of $x \in R$ which are compatible (in $R$) with all $\varphi(y)$ for $y \in G[\alpha^*]$ (the generic filter for $R[\alpha^*]$) or, equivalently, the set of $x \in R$ such that $x[\alpha^*] \in G[\alpha^*]$. So Lemma 4.27 (relativized to $R[\alpha^*]$) implies:

$\begin{align*}
\text{(5.3)} & \quad R/R[\alpha^*] \text{ is the set of } x \in R \text{ that canonically embed (up to } \alpha^*) \text{ into } P_{\alpha^*}.
\end{align*}$

**Setup.** Fix some $\alpha^* < \omega_2$ of uncountable cofinality.\(^{51}\) Let $G[\alpha^*]$ be $R[\alpha^*]$-generic over $V$ and work in $V^* := V[G[\alpha^*]]$. Set $P^* = (P^*_\beta)^{\beta < \alpha^*}$, the generic alternating iteration added by $R[\alpha^*]$. Let $R^*$ be the quotient $R/R[\alpha^*].$

We claim that $R^*$ satisfies (in $V^*$) all the properties that we proved in Section 4 for $R$ (in $V$), with the obvious modifications. In particular:

---

\(^{51}\)The cofinality is probably completely irrelevant, but the picture is clearer this way.
(A) \(\alpha \). \(\mathbb{R}^*\) is \(\aleph_2\)-cc, since it is the quotient of an \(\aleph_2\)-cc forcing.

(B) \(\alpha \). \(\mathbb{R}^*\) does not add new reals (and more generally, no new HCON objects), since it is the quotient of a \(\sigma\)-closed forcing.\(^{52}\)

(C) \(\alpha \). Let \(G^*\) be \(\mathbb{R}^*\)-generic over \(V^*\). Then \(G^*\) is \(\mathbb{R}\)-generic over \(V\), and therefore Corollary 4.4 holds for \(G^*\). (Note that \(P_{\omega_2}^\ast \) and then \(P_{\omega_2}\) is constructed from \(G^*\).) Moreover, it is easy to see\(^{53}\) that \(P\) starts with \(P^\ast\).

(D) \(\alpha \). In particular, we get a variant of Lemma 4.28. The following is forced by \(\mathbb{R}^*\):

Let \(N \prec H[\mathbb{G}]^*(\chi^*)\) be countable, and let \(y\) be the ord-collapse of \((N, P)\). Then \(y \in G^*\). Moreover: If \(x \in G^* \cap N\), then \(y \leq x\).

We can use the last item to prove the \(\mathbb{R}^*\)-version of Fact 4.4.

Corollary 5.4. In \(V^*\), the following holds:

1. Assume that \(x \in \mathbb{R}^*\) forces that \(p \in P_{\omega_2}\). Then there is a \(y \leq x\) and a \(p^y \in P_{\omega_2}^y\) such that \(y\) forces \(p^y = \ast p\).

2. Assume that \(x \in \mathbb{R}^*\) forces that \(\dot{r}\) is a \(P_{\omega_2}^\ast\)-name of a real. Then there is a \(y \leq x\) and a \(P_{\omega_2}^y\)-name \(\dot{r}^y\) such that \(y\) forces that \(\dot{r}^y\) and \(\dot{r}\) are equivalent as \(P_{\omega_2}^\ast\)-names.

Proof. We only prove (1), the proof of (2) is similar.

Let \(G^*\) contain \(x\). In \(V[\mathbb{G}]\), pick an elementary submodel \(N\) containing \(x, p, \dot{P}\) and let \((M^x, \dot{P}^x, \dot{p}^x)\) be the ord-collapse of \((N, \dot{P}, p)\). Then \(z \in G^*\). This whole situation is forced by some \(y \leq z \leq x \in G^*\). So \(y\) and \(p^y\) is as required, where \(p^y \in P_{\omega_2}^y\) is the canonical image of \(p^x\). \(\square\)

We also get the following analogue of Fact 4.4:

In \(V^*\) we have: Let \(x \in \mathbb{R}^*\). Assume that \(\dot{P}\) is an alternating iteration that extends \(\dot{P}\) and that \(x = (M^x, \dot{P}^x)\) embeds into \(\dot{P}\), and that \(N \prec H(\chi^*)\) contains \(x\) and \(\dot{P}\). Let \(y = (M^y, \dot{P}^y)\) be the ord-collapse of \((N, \dot{P})\). Then \(y \in \mathbb{R}^*\) and \(y \leq x\).

We now claim that \(\mathbb{R} * P_{\omega_2}\) forces BC+dBC. We know that \(\mathbb{R}\) is forcing equivalent to \(\mathbb{R}[\alpha^*] \ast \mathbb{R}^*\). Obviously we have

\[\mathbb{R} \ast P_{\omega_2} = \mathbb{R}[\alpha^*] \ast \mathbb{R}^* \ast P_{\omega_2} \ast P_{\alpha^*}\]

(where \(P_{\alpha^*} \ast P_{\omega_2}\) is the quotient of \(P_{\omega_2}\) and \(P_{\alpha^*}\)). Note that \(P_{\omega_2} \ast P_{\alpha^*}\) is already determined by \(\mathbb{R}[\alpha^*]\), so \(\mathbb{R}^* \ast P_{\alpha^*}\) is (forced by \(\mathbb{R}[\alpha^*]\) to be) a product \(\mathbb{R}^* \ast P_{\alpha^*} = P_{\alpha^*} \ast \mathbb{R}^*\).

But note that this is not the same as \(P_{\alpha^*} \ast \mathbb{R}^*\), where we evaluate the definition of \(\mathbb{R}^*\) in the \(P_{\alpha^*}\)-extension of \(V[\mathbb{G}]\). We would get new candidates and therefore new conditions in \(\mathbb{R}^*\) after forcing with \(P_{\alpha^*}\). In other words, we cannot just argue as follows:

Wrong argument. \(\mathbb{R} \ast P_{\omega_2}\) is the same as \((\mathbb{R}[\alpha^*] \ast P_{\alpha^*}) \ast (\mathbb{R}^* \ast P_{\omega_2} \ast P_{\alpha^*})\), so given an \(\mathbb{R} \ast P_{\omega_2}\)-name \(X\) of a set of reals of size \(\aleph_1\), we can choose \(\alpha^*\) large enough so

\(^{52}\)It is easy to see that \(\mathbb{R}^*\) is even \(\sigma\)-closed, by “relativizing” the proof for \(\mathbb{R}\), but we will not need this.

\(^{53}\)For \(\beta \leq \alpha^*\), let \(P_{\beta}^\ast\) be the direct limit of \((G[\alpha^*])^\beta\) and \(P_{\beta}^\ast\) the direct limit of \(G^* \ast \beta\). The function \(k_\beta : P_{\beta}^\ast \rightarrow P_{\beta}^\ast\) that maps \((x, p)\) to \((p(x), p)\) preserves \(\leq\) and \(\perp\) and is surjective modulo \(\ast\); see Fact 4.4. So it is clear that defining \(P_{\beta}^\ast \ast \beta\) by induction from \(P_{\beta}^\ast\) yields the same result as defining \(P\) from \(P_{\beta}^\ast\).
that \(X\) is an \((\mathbb{R}[\alpha^* \ast P_{\alpha^*}])\)-name. Then, working in the \((\mathbb{R}[\alpha^* \ast P_{\alpha^*}])\)-extension, we just apply Lemmas 5.1 and 5.2.

So what do we do instead? Assume that \(\hat{X} = \{\hat{\xi}_i : i \in \omega_1\}\) is an \(\mathbb{R} \ast P_{\omega_2}\)-name for a set of reals of size \(\aleph_1\). So there is a \(\beta < \omega_2\) such that \(\hat{X}\) is added by \(\mathbb{R} \ast P_{\beta}\). In the \(\mathbb{R}\)-extension, \(P_{\beta}\) is ccc, therefore we can assume that each \(\hat{\xi}_i\) is a system of countably many countable antichains \(A^i_\alpha\) of \(P_{\beta}\), together with functions \(f^i_\alpha : A^i_\alpha \rightarrow \{0, 1\}\).

For the following argument, we prefer to work with the equivalent \(P_{\beta}^*\) instead of \(P_{\beta}\). We can assume that each of the sequences \(B_i := (A^i_\alpha, f^i_\alpha)\) is an element of \(V\) (since \(P_{\beta}^*\) is a subset of \(V\) and since \(\mathbb{R}\) is \(\sigma\)-closed). So each \(B_i\) is decided by a maximal antichain \(Z_i\) of \(\mathbb{R}\). Since \(\mathbb{R}\) is \(\aleph_2\)-cc, these \(\aleph_1\) many antichains all are contained in some \(\mathbb{R}[\alpha^*]\) with \(\alpha^* \geq \beta\).

So in the \(\mathbb{R}[\alpha^*]\)-extension \(V^*\) we have the following situation. Each \(\xi_i\) is a very "absolute"\(^{54}\) \(\mathbb{R}^* \ast P_{\alpha^*}\)-name (or, equivalently, \(\mathbb{R}^* \times P_{\alpha^*}\)-name). In fact they are already determined by antichains that are in \(P_{\alpha^*}\) and do not depend on \(\mathbb{R}^*\). So we can interpret them as \(P_{\alpha^*}\)-names.

Note that:

\[\text{The } \xi_i \text{ are forced (by } \mathbb{R}^* \ast P_{\alpha^*} \text{) to be pairwise different, and} \]
\[\text{therefore already by } P_{\alpha^*}. \]

Now we are finally ready to prove that \(\mathbb{R} \ast P_{\omega_2}\) forces that every uncountable \(X\) is neither smz nor sm. It is enough to show that for every name \(\tilde{X}\) of an uncountable set of reals of size \(\aleph_1\), the forcing \(\mathbb{R} \ast P_{\omega_2}\) forces that \(\tilde{X}\) is neither smz nor sm. For the rest of the proof we fix such a name \(\tilde{X}\), the corresponding \(\xi_i\)'s (for \(i \in \omega_1\)), and the appropriate \(\alpha^*\) as above. From now on, we work in the \(\mathbb{R}[\alpha^*]\)-extension \(V^*\).

So we have to show that \(\mathbb{R}^* \ast P_{\omega_2}\) forces that \(\tilde{X}\) is neither smz nor sm.

After all our preparations, we can just repeat the proofs of BC (Lemma 5.1) and dBC (Lemma 5.2) of Section 5 with the following modifications. The modifications are the same for both proofs; for better readability we describe the results of the change only for the proof of dBC.

1. Change: Instead of an arbitrary ultralaver position \(\alpha < \omega_2\), we obviously have to choose \(\alpha \geq \alpha^*\).

For the dBC: we choose an arbitrary ultralaver position \(\alpha \geq \alpha^*\). The Janus forcing \(Q_{\alpha+1}\) adds a (canonically defined code for \(a\)) null set \(\mathbb{Z}_V\).

2. Change: No change here. (Of course we now have an \(\mathbb{R}^* \ast P_{\alpha^*}\)-name \(\hat{X}\) instead of a ground model set.)

For the dBC: It is enough to show that \(\hat{X} + \mathbb{Z}_V = 2^\omega\) in the \(\mathbb{R}^* \ast P_{\omega_2}\)-extension of \(V^*\) or, equivalently, in every \(\mathbb{R}^* \ast P_{\beta}\)-extension (\(\alpha < \beta < \omega_2\)). So assume towards a contradiction that there is a \(\beta > \alpha\) and an \(\mathbb{R}^* \ast P_{\beta}\)-name \(\hat{\xi}^*\) of a real such that some \((x, p) \in \mathbb{R}^* \ast P_{\omega_2}\) forces that \(\hat{\xi}^* \notin \hat{X} + \mathbb{Z}_V\).

3. Change: no change. (But we use Corollary 5.4 instead of Lemma 5.15.)

For dBC: Using Corollary 5.4\(^2\), without loss of generality \(x\) forces \(p^x =^* p\) and there is a \(P_{\beta}^*\)-name \(\hat{\xi}^*\) in \(M^x\) such that \(\hat{\xi}^* = \hat{\xi}\) is forced.

4. Change: The iteration obviously has to start with the \(\mathbb{R}[\alpha^*]\)-generic iteration \(P^*\) (which is ccc); the rest is the same.

For dBC: In \(V^*\) we construct an iteration \(\hat{P}\) in the following way:

\(^{54}\)Or "nice" in the sense of [Kum80, 5.11].
(a1) Up to $\alpha^*$, we use the iteration $\bar{P}$ (which already lives in our current universe $V^*$). As explained above in the paragraph preceding (5.6), $\bar{X}$ can be interpreted as a $P_{\alpha^*}$-name $\hat{X}$, and by (5.6), $\hat{X}$ is forced to be uncountable.

(a2) We continue the iteration from $\alpha^*$ to $\alpha$ in a way that embeds $x$ and such that $P_\alpha$ is proper. So $P_\alpha$ will force that $\hat{X}$ is still uncountable.

(b1) Let $Q_\alpha$ be any ultralaver forcing (over $Q_{\alpha^*}$). Then $Q_\alpha$ forces that $\hat{X}$ is not thin.

(b2) Let $Q_{\alpha+1}$ be a countable Janus forcing. So $Q_{\alpha+1}$ forces $\hat{X} + \check{Z}_\chi = 2^\omega$.

(c) We continue the iteration in a $\sigma$-centered way. I.e., we use an almost FS iteration over $x$ of ultralaver forcings and countable Janus forcings, using trivial $Q_\zeta$ for all $\zeta \notin M^x$.

(d) So $P_\beta$ still forces that $\hat{X} + \check{Z}_\chi = 2^\omega$ and, in particular, that $\check{x} \in \hat{X} + \check{Z}_\chi$.

We now pick (in $V^*$) a countable $N \prec H(\chi^*)$ containing everything and ord-collapse $(N, \bar{P})$ to $y \leq x$, by (5.5). The HCON object $y$ is of course in $V$ (and even in $\mathbb{R}$), but we can say more: Since the iteration $\bar{P}$ starts with the $[\mathbb{R}\mid\alpha^*]$-generic iteration $P^*$, the condition $y$ will be in the quotient forcing $\mathbb{R}^*$.

Set $\check{X}^y := \check{X} \cap M^y$ (which is the image of $\check{X}$ under the collapse, since we view $\check{X}$ as a set of HCON-names). By elementarity, $M^y$ thinks that (a)–(d) above holds for $P^y$ and that $\check{X}^y$ is forced to be uncountable. Note that $\check{X}^y \subseteq \check{X}$ in the following sense: Whenever $G^* \ast H$ is $\mathbb{R}^* \ast P_{\omega_2}$-generic over $V^*$ and $y \in G^*$, then the evaluation of $\check{X}^y$ in $M^y[H^y]$ is a subset of the evaluation of $\check{X}$ in $V^*[G^* \ast H]$.

(5) Change: No change here.

For dBC: We get our desired contradiction as follows:

Let $G^*$ be $\mathbb{R}^*$-generic over $V^*$ and contain $y$. Let $H_\beta$ be $P_\beta$-generic over $V^*[G^*]$ and contain $p$. So $M^y[H_\beta^y]$ thinks that $r = x + z$ for some $x \in X^y \subseteq X$ and $z \in Z_\chi$, contradicting (2).

6. A WORD ON VARIANTS OF THE DEFINITIONS

The following is not needed for understanding the paper; we just briefly comment on alternative ways some notions could be defined.

6A. Regarding alternating iterations. We call the set of $\alpha \in \omega_2$ such that $Q_{\alpha}$ is (forced to be) non-trivial the “true domain” of $\bar{P}$ (we use this notation in this remark only). Obviously $\bar{P}$ is naturally isomorphic to an iteration whose length is the order type of its true domain. In Definitions 4.4 and 4.6, we could have imposed the following additional requirements. All these variants lead to equivalent forcing notions.

(1) $M^x$ is (an ord-collapse of) an elementary submodel of $H(\chi^*)$.

This is equivalent, as conditions coming from elementary submodels are dense in our $\mathbb{R}$, by Fact 4.4.

---

Note that we get the same Borel code, whether we evaluate $\check{Z}_\chi$ in $M^y[H_\beta^y]$ or in $V^*[G^* \ast H_\beta]$. Accordingly, the actual Borel set of reals coded by $Z_\chi$ in the smaller universe is a subset of the corresponding Borel set in the larger universe.
While this definition looks much simpler and therefore nicer (we could replace ord-transitive models by the better understood elementary models), it would not make things easier and just “hides” the point of the construction. For example, we use models $M^x$ that are (an ord-collapse of) an elementary submodel of $H^V(\chi^*)$ for some forcing extension $V'$ of $V$.

(2) Require that $(M^x$ thinks that) the true domain of $\bar{P}^x$ is $\omega_2$. This is equivalent for the same reason as (1) (and this requirement is compatible with (1)). This definition would allow to drop the “trivial” option from the definition. The whole proof would still work with minor modifications; in particular, because of the following fact:

The finite support iteration of $\sigma$-centered forcing notions of length $<\omega_2$ is again $\sigma$-centered.

We chose our version for two reasons: first, it seems more flexible, and second, we were initially not aware of \((\ref{6.1})\).

(3) Alternatively, require that $(M^x$ thinks that) the true domain of $\bar{P}^x$ is countable. Again, equivalence can be seen as in (1), and again (3) is compatible with (1) but obviously not with (2). This requirement would not make the definition easier, so there is no reason to adopt it. It would have the slight inconvenience that instead of using ord-collapses as in Fact \((\ref{4.4})\), we would have to put another model on top to make the iteration countable. Also, it would have the (purely aesthetic) disadvantage that the generic iteration itself does not satisfy this requirement.

(4) Also, we could have dropped the requirement that the iteration is proper. It is never directly used, and “densely” $\bar{P}$ is proper anyway. (E.g., in (4)(a) of the proof of Lemma \((\ref{5.1})\) we would just construct $\bar{P}$ up to $\alpha$ to be proper or even ccc, so that $X$ remains uncountable.)

6.B. Regarding almost CS iterations and separative iterands. Recall that in Definition \((\ref{3.6})\) we required that each iterand $Q_\alpha$ in a partial CS iteration is separative. This implies the property (actually, the three equivalent properties) from Fact \((\ref{3.8})\). Let us call this property “suitability” for now. Suitability is a property of the limit $P_\varepsilon$ of $\bar{P}$. Suitability always holds for finite support iterations and for countable support iterations. However, if we do not assume that each $Q_\alpha$ is separative, then suitability may fail for partial CS iterations. We could drop the separativity assumption and instead add suitability as an additional natural requirement to the definition of a partial CS limit.

The disadvantage of this approach is that we would have to check in all constructions of partial CS iterations that suitability is indeed satisfied (which we found to be straightforward but rather cumbersome; in particular, in the case of the almost CS iteration).

In contrast, the disadvantage of assuming that $Q_\alpha$ is separative is minimal and purely cosmetic. It is well known that every quasiorder $Q$ can be made into a

\[56\text{We are grateful to Stefan Geschke and Andreas Blass for pointing out this fact. The only references we are aware of are [Tal94] proof of Lemma 2] and [Bla11].}\]
separative one which is forcing equivalent to the original $Q$ (e.g., by just redefining
the order to be $\leq^*_Q$).

6.C. Regarding preservation of random and quick sequences. Recall Definition [1.50] of local preservation of random reals and Lemma [3.32]
In some respect the dense sets $D_n$ are unnecessary. For ultralaver forcing $L\bar{D}$,
the notion of a “quick” sequence refers to the sets $D_n$ of conditions with stem of
length at least $n$.
We could define a new partial order on $L\bar{D}$ as follows:
$q \leq' p \iff (q = p) \text{ or } (q \leq p, \text{ and the stem of } q \text{ is strictly longer than the stem of } p)$.
Then $(L\bar{D}, \leq)$ and $(L\bar{D}, \leq')$ are forcing equivalent, and any $\leq'$-interpretation of
a new real will automatically be quick.
Note however that $(L\bar{D}, \leq')$ is no longer separative. Therefore we chose not
to take this approach, since losing separativity causes technical inconvenience, as
described in Section 6.B.

Acknowledgement
The authors are grateful to the anonymous referee for pointing out several unclar-
ities in the original version.
