POLAR ORBITOPE

LEONARDO BILIOTTI, ALESSANDRO GHIGI AND PETER HEINZNER

Abstract. We study polar orbitopes, i.e. convex hulls of orbits of a polar representation of a compact Lie group. They are given by representations of $K$ on $p$, where $K$ is a maximal compact subgroup of a real semisimple Lie group $G$ with Lie algebra $\mathfrak{g} = \mathfrak{t} \oplus \mathfrak{p}$. The face structure is studied by means of the gradient momentum map and it is shown that every face is exposed and is again a polar orbitope. Up to conjugation the faces are completely determined by the momentum polytope. There is a tight relation with parabolic subgroups: the set of extreme points of a face is the closed orbit of a parabolic subgroup of $G$ and for any parabolic subgroup the closed orbit is of this form.

1. Introduction

If $K$ is a compact group and $K \to \text{Gl}(V)$ is a real representation, the convex hull of a $K$-orbit is called an orbitope [22]. If $V$ is provided with a $K$-invariant scalar product, the representation is said to be polar if there is a linear subspace $S \subset V$ that intersects perpendicularly all the orbits of $K$. An important class of examples is given by the adjoint representations of compact Lie groups. In [2] we studied the orbitopes of these actions. They are equivariantly isomorphic to Satake-Furstenberg compactifications of symmetric spaces of type $K^C/K$. One homeomorphism has been described in algebraic terms in [17]. Another homeomorphism has been constructed in [1] (in the case of an integral orbit) using integration of the momentum map on a flag manifold. This geometric construction was developed by Bourguignon, Li and Yau in the case of $\mathbb{P}^n$.

In the present paper we study the orbitopes of a polar representation of a compact group. Let $G$ be a real connected semisimple Lie group and let $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$ be a Cartan decomposition of its Lie algebra. Let $K$ be a the maximal compact subgroup with Lie algebra $\mathfrak{k}$. Then the adjoint action of $K$ preserves $\mathfrak{p}$ and its restriction to $\mathfrak{p}$ is a polar representation. By a theorem of Dadok [5, Prop. 6] if $V$ is any polar representation of a group $K_1$, there is a semisimple Lie group $G$ such that $V$ can be identified with $\mathfrak{p}$ so that the orbits of $K_1$ coincide with the orbits of $\text{Ad} K$ on $\mathfrak{p}$. Therefore to understand the orbitopes of polar representations it is sufficient to study the $K$-orbitopes on $\mathfrak{p}$.

The study of these orbitopes is also needed in order to generalize the results in [1] to general symmetric spaces and this is one of the motivations for our work.

Our set up is the following. Let $U$ be compact Lie group and let $U^C$ be its complexification. A closed subgroup $G \subset U^C$ is called compatible if $G = K \cdot \exp \mathfrak{p}$ where $K := G \cap U$ and $\mathfrak{p} := \mathfrak{g} \cap i\mathfrak{u}$. It follows that $K$ is a maximal compact subgroup of $G$ and that $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$. $K$ acts on $\mathfrak{g}$ by the adjoint action and $\mathfrak{p}$ is invariant. Therefore we get an action of $K$ on $\mathfrak{p}$. The objects that we wish to study are the orbits of this action and their convex hulls. It is easy to see that one can reduce to the case in which $U$ and $G$ are semisimple (see [3,2]). If $O \subset \mathfrak{p}$ is a $K$-orbit, we denote by $\hat{O}$ its convex hull. We will assume throughout the paper that $G$ is connected. It is a fundamental fact that the action of $K$ on $O$ extends to an action of $G$, see e.g. [12, Prop. 6]. If $a \subset \mathfrak{p}$ is a maximal subalgebra, then by Kostant convexity theorem [18], the orthogonal projection of $O$ onto $a$ is a convex polytope $P$ given by the convex hull of a Weyl group orbit. In particular the Weyl group acts on the set $\mathcal{F}(P)$ of faces of $P$ and similarly $K$ acts on the set $\mathcal{F}(\hat{O})$ of faces of $\hat{O}$.
Our main result is the following.

**Theorem 1.1.** Let $P \subset \mathfrak{a}$ be the momentum polytope associated to $\mathcal{O}$. If $\sigma$ is a face of $P$ and $K^{\sigma \perp}$ is the centralizer of the normal space $\sigma \perp \subset \mathfrak{a}$, then $K^{\sigma \perp} \cdot \sigma$ is a face of $\hat{\mathcal{O}}$. Moreover the map $\sigma \mapsto K^{\sigma \perp} \cdot \sigma$ induces a bijection between $\mathcal{F}(P)/W$ and $\mathcal{F}(\hat{\mathcal{O}})/K$.

The correspondence between $\mathcal{F}(\hat{\mathcal{O}})/K$ and $\mathcal{F}(P)/W$ holds for a general polar representation, see Remark 3.1 at p. 22. Applied to the case $G = U_C$ this theorem gives the results proven in [2]. The setting of the present paper is more general than the one considered there. The pairs $(G,K)$ with $G$ compatible contain all Riemannian symmetric pairs of noncompact type, while the pairs $(U_C, U)$ correspond to symmetric pairs of type IV [13, p. 516]. The particular cases $U = SU(n)$, $G = SL(n, \mathbb{R})$ and $U = SO(n)$, $G = SO(n, \mathbb{C})$ have been considered in [22]. The case where $\mathcal{O}$ can be realized as the Shilov boundary of a Hermitian symmetric domain has been studied in [4, Prop. 2.1].

We outline the main steps of the proof.

Among the faces of a convex set are the exposed faces (see §2.1). In the case of $\hat{\mathcal{O}}$ the study of these faces is equivalent to the understanding of the height functions on $\mathcal{O}$ (§3.1). This is a classical subject, going back to the paper [6] by Duistermaat, Kolk and Varadarajan and to Heckman’s thesis [8]. The results are very efficiently described in the language of the gradient momentum map (which is recalled in §2.4). The set of extreme points $\text{ext} F$ of an exposed face $F$ is connected and is an orbit of a centralizer $K^\beta \subset K$, where $\beta$ is an element of $\mathfrak{p}$ (Proposition 3.1). In general the group $K^\beta$ is not connected. An inductive argument shows that any face $F \subset \hat{\mathcal{O}}$ (not necessarily exposed) is an orbitope of the centralizer $K^s$ of some subalgebra $s \subset \mathfrak{p}$ (Proposition 3.4). If $\mathfrak{a} \subset \mathfrak{p}$ is a maximal subalgebra containing $s$, we show that $F \cap \mathfrak{a}$ is a face of the momentum polytope and that $F \cap \mathfrak{a}$ determines $F$ (Proposition 3.6). Here we use in an essential way the Kostant convexity theorem.

An important conclusion is that all faces of $\hat{\mathcal{O}}$ are exposed (Theorem 3.2). This answers Question 1 of [22] for polar orbitopes. Next recall that the $K$-action on $\mathcal{O}$ extends to an action of the group $G$ (see §2.5 below). We analyze the influence of the $G$-action on the geometry of the extreme points of the faces (§3.3). It turns out that there is a strong link between the parabolic subgroups of $G$ and the faces of $\hat{\mathcal{O}}$. In §3.3 we show the following.

**Theorem 1.2.** The set $\{\text{ext} F : F$ a nonempty face of $\hat{\mathcal{O}}\}$ coincides with the set of all closed orbits of parabolic subgroups of $G$. 
Using these results we finally set up the correspondence between the faces of $\tilde{O}$ and the faces of $P$ and prove Theorem 1.1 (§3.4).

In the final section we briefly explain how the boundary of $\tilde{O}$ is stratified by face type and how the Satake combinatorics can be used to describe the faces of the orbitope in terms of root data.

2. Preliminaries

2.1. Convex geometry. It is useful to recall a few definitions and results regarding convex sets (see e.g. [24] and [2, §1]). Let $V$ be a real vector space with a scalar product $\langle \cdot, \cdot \rangle$ and let $E \subset V$ be a compact convex subset. The relative interior of $E$, denoted $\text{relint } E$, is the interior of $E$ in its affine hull. A face $F$ of $E$ is a convex subset $F \subset E$ with the following property: if $x, y \in E$ and $\text{relint } [x,y] \cap F \neq \emptyset$, then $[x,y] \subset F$. The extreme points of $E$ are the points $x \in E$ such that $\{x\}$ is a face. Since $E$ is compact the faces are closed [24, p. 62]. A face distinct from $E$ and $\emptyset$ will be called a proper face. The support function of $E$ is the function $h_{E}: V \to \mathbb{R}$, $h_{E}(u) = \max_{x \in E} \langle x, u \rangle$. If $u \neq 0$, the hyperplane $H(E,u) := \{ x \in E : \langle x, u \rangle = h_{E}(u) \}$ is called the supporting hyperplane of $E$ for $u$. The set

$$
F_{u}(E) := E \cap H(E,u)
$$

is a face and it is called the exposed face of $E$ defined by $u$. In general not all faces of a convex subset are exposed. A simple example is given by the convex hull of a closed disc and a point outside the disc: the resulting convex set is the union of the disc and a triangle. The two vertices of the triangle that lie on the boundary of the disc are non-exposed 0-faces.

Lemma 2.1 ([2, Lemma 3]). If $F$ is a face of a convex set $E$, then $\text{ext } F = F \cap \text{ext } E$.

Lemma 2.2. If $G$ is a compact group and $V$ is a representation space of $G$ define

$$
\rho : V \to V^{G} \quad \rho(v) := \int_{G} gx \, dg
$$

where $dg$ denotes the Haar measure on $G$. Then $V = V^{G} \oplus \ker \rho$. If $x \in V$ and $x = x_{0} + x_{1}$ in this decomposition, then

a) $G \cdot x = x_{0} + G \cdot x_{1}$;

b) $\text{conv}(G \cdot x) = x_{0} + \text{conv}(G \cdot x_{1})$;

c) $x_{0}$ is the unique fixed point of $G$ contained in $\text{conv}(G \cdot x)$;

d) $x_{0} \in \text{relint } \text{conv}(G \cdot x)$. 
Proof. That $V = V^G \oplus \ker \rho$ follows from the fact that $\text{Im} \rho = V^G$ and $\rho^2 = \rho$. (a) and (b) are immediate. Since $x_0 = \rho(x)$, it follows from the definition of $\rho$ that $x_0 \in \text{conv}(G \cdot x)$. If $y \in \text{conv}(G \cdot x)$ is another fixed point, then $y_0 = x_0$ and $y_1 \in \ker \rho \cap V^G$. Hence $y_1 = 0$ and $y = x_0$. This proves (c). By Theorem 2.1 there is a unique face $F \subset \text{conv}(G \cdot x)$ such that $x_0 \in \text{relint} F$. Since $\text{conv}(G \cdot x)$ is $G$-invariant and $x_0$ is fixed by $G$, also $F$ is $G$-invariant, and hence also $\text{ext} F$. Since $\text{ext} F \subset \text{ext}(\text{conv}(G \cdot x)) = G \cdot x$, it follows that $\text{ext} F = G \cdot x$ and hence that $F = \text{conv}(G \cdot x)$.

Lemma 2.3 ([2] Prop. 5). If $F \subset E$ is an exposed face, the set $C_F := \{u \in V : F = F_u(E)\}$ is a convex cone. If $G$ is a compact subgroup of $O(V)$ that preserves both $E$ and $F$, then $C_F$ contains a fixed point of $G$.

Theorem 2.1 ([24] p. 62). If $E$ is a compact convex set and $F_1, F_2$ are distinct faces of $E$ then $\text{relint} F_1 \cap \text{relint} F_2 = \emptyset$. If $G$ is a nonempty convex subset of $E$ which is open in its affine hull, then $G \subset \text{relint} F$ for some face $F$ of $E$. Therefore $E$ is the disjoint union of the relative interiors of its faces.

Lemma 2.4 ([2] Lemma 7). If $E$ is a compact convex set and $F \subsetneq E$ is a face, then $\dim F < \dim E$.

Lemma 2.5 ([2] Lemma 8). If $E$ is a compact convex set and $F \subset E$ is a face, then there is a chain of faces $F_0 = F \subset F_1 \subset \cdots \subset F_k = E$ which is maximal, in the sense that for any $i$ there is no face of $E$ strictly contained between $F_{i-1}$ and $F_i$.

Lemma 2.6 ([2] Lemma 9). If $E$ is a convex subset of $\mathbb{R}^n$, $M \subset \mathbb{R}^n$ is an affine subspace and $F \subset E$ is a face, then $F \cap M$ is a face of $E \cap M$.

2.2. Compatible subgroups. (See [10 11].) If $G$ is a Lie group with Lie algebra $\mathfrak{g}$ and $E, F \subset \mathfrak{g}$, we set

$$E^F := \{\eta \in E : [\eta, \xi] = 0, \forall \xi \in F\}$$

$$G^F = \{g \in G : \text{Ad} g(\xi) = \xi, \forall \xi \in F\}.$$

If $F = \{\beta\}$ we write simply $E^\beta$ and $G^\beta$. Let $U$ be compact Lie group. Let $U^C$ be its universal complexification which is a linear reductive complex algebraic group. We denote by $\theta$ both the conjugation map $\theta : u^C \to u^C$ and the corresponding group isomorphism $\theta : U^C \to U^C$. Let $f : U \times iu \to U^C$ be the diffeomorphism $f(g, \xi) = g \exp \xi$. Let $G \subset U^C$ be a closed subgroup. Set $K := G \cap U$ and $\mathfrak{p} := \mathfrak{g} \cap i\mathfrak{u}$. We say that $G$ is compatible if $f(K \times \mathfrak{p}) = G$. The restriction of $f$ to $K \times \mathfrak{p}$ is then a diffeomorphism onto $G$. It follows that $K$ is a maximal compact subgroup of $G$ and that $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{p}$. Note that $G$ has finitely many connected components. Since $U$ can be embedded in
Gl(N, C) for some N, and any such embedding induces a closed embedding of \( U^C \), any compatible subgroup is a closed linear group. Moreover g is a real reductive Lie algebra, hence \( g = \mathfrak{j}(g) \oplus \mathfrak{g, g} \). Denote by \( G_{ss} \) the analytic subgroup tangent to \([g, g]\). Then \( G_{ss} \) is closed and \( G = Z(G)^0 \cdot G_{ss} \) [16] p. 442.

**Lemma 2.7.** a) If \( G \subset U^C \) is a compatible subgroup, and \( H \subset G \) is closed and \( \theta \)-invariant, then \( H \) is compatible if and only if \( H \) has only finitely many connected components.

b) If \( G \subset U^C \) is a connected compatible subgroup, then \( G_{ss} \) is compatible.

c) If \( G \subset U^C \) is a compatible subgroup, and \( E \subset p \) is any subset, then \( G^E \) is compatible.

**Proof.** (a) This follows from the more general observation that a closed \( \theta \)-invariant subgroup \( G \subset U^C \) is compatible if and only if it has finitely many connected components. This is proven in Lemma 1.1.3 in [19] p.14. For the reader’s convenience we recall the argument. If \( G \) is compatible, then it retracts onto \( K \), which is compact and therefore has finitely many connected components. Conversely assume that \( G/G^0 \) be finite. Since \( G \) is closed, \( f(K \times p) \) is a closed subset of \( G \). Since \( G \) is \( \theta \)-invariant, \( f(K \times p) \) has the same dimension as \( G \) and is therefore also open. Therefore it contains \( G^0 \) and is a union of connected components of \( G \). Given \( g \in G \) write \( g = u \exp \xi \) with \( u \in U \) and \( \xi \in iu \). Then \( g^\theta(g^{-1}) = \exp(2 \text{Ad}(u)\xi) \) and since \( G/G^0 \) is finite there is a natural number \( N > 0 \) such that \( (g^\theta(g^{-1}))^N = \exp(2N \text{Ad}(u)\xi) \in G^0 \). Hence \( \text{Ad}(u)\xi \in p, u = \exp(-\text{Ad}(u)\xi) g \in G \cap U = K \) and \( \xi \in p \). (b)

Since \([g, g]\) is \( \theta \)-invariant and \( G_{ss} \) is connected, \( G_{ss} \) is \( \theta \)-invariant. Since it is also closed, it is compatible by (a) (c) see [16] Proposition 7.25 p. 452. □

Let \( \langle , \rangle \) be a fixed \( U \)-invariant scalar product on \( u \). We use it to identify \( u \cong u^* \). We also denote by \( \langle , \rangle \) the scalar product on \( iu \) such that multiplication by \( i \) is an isometry of \( u \) onto \( iu \). One can define an \( \mathbb{R} \)-bilinear form \( B \) on \( u^C \) by imposing \( B(u, iu) = 0, B = -\langle , \rangle \) on \( u \) and \( B = \langle , \rangle \) on \( iu \). Then \( B \) is \( \text{Ad} U^C \)-invariant and nondegenerate.

**2.3. Parabolic subgroups.** (See e.g. [3] p. 28ff, [16].) If \( G \subset U^C \) is compatible, \( g = \mathfrak{t} \oplus \mathfrak{p} \) is reductive. A subalgebra \( q \subset g \) is parabolic if \( q^C \) is a parabolic subalgebra of \( g^C \). One way to describe the parabolic subalgebras of \( g \) is by means of restricted roots. If \( a \subset \mathfrak{p} \) is a maximal subalgebra, let \( \Delta(g, a) \) be the (restricted) roots of \( g \) with respect to \( a \), let \( g_\lambda \) denote the root space corresponding to \( \lambda \) and let \( g_0 = m \oplus a \), where \( m = \mathfrak{j}(a) \). Let \( \Pi \subset \Delta(g, a) \) be a base and let \( \Delta_+ \) be the set of positive roots. If \( I \subset \Pi \) set
\[ \Delta_I := \text{span}(I) \cap \Delta. \] Then
\[ q_I := g_0 \oplus \bigoplus_{\lambda \in \Delta_I \cup \Delta_+} g_\lambda \]
is a parabolic subalgebra. Conversely, if \( q \subseteq g \) is a parabolic subalgebra, then there are a maximal subalgebra \( a \subseteq p \) contained in \( q \), a base \( \Pi \subseteq \Delta(g, a) \) and a subset \( I \subseteq \Pi \) such that \( q = q_I \). We can further introduce
\[ a_I := \bigcap_{\lambda \in I} \ker \lambda \quad a_I^r := a_I^\perp \]
\[ (3) \]
\[ n_I := \bigoplus_{\lambda \in \Delta_+ \setminus \Delta} g_\lambda \quad m_I := m \oplus a_I^r \oplus \bigoplus_{\lambda \in \Delta_I} g_\lambda. \]
Then \( q_I = m_I \oplus a_I \oplus n_I \). Since \( \theta g_\lambda = g_{-\lambda} \), it follows that \( q_I \cap \theta q_I = a_I \oplus m_I \). This latter Lie algebra coincides with the centralizer of \( a_I \) in \( g \). It is a Levi factor of \( q_I \) and
\[ (4) \] \[ a_I = z(q_I \cap \theta q_I) \cap p. \]
Another way to describe parabolic subalgebras of \( g \) is the following. If \( \beta \in p \), the endomorphism \( \text{ad} \beta \in \text{End} g \) is diagonalizable over \( \mathbb{R} \). Denote by \( V_\lambda(\text{ad} \beta) \) the eigenspace of \( \text{ad} \beta \) corresponding to the eigenvalue \( \lambda \). Set
\[ g^{\beta+} := \bigoplus_{\lambda \geq 0} V_\lambda(\text{ad} \beta). \]

**Lemma 2.8.** For any \( \beta \) in \( p \), \( g^{\beta+} \) is a parabolic subalgebra of \( g \). If \( q \subseteq g \) is a parabolic subalgebra, there is some vector \( \beta \in p \) such that \( q = g^{\beta+} \). The set of all such vectors is an open convex cone in \( z(q \cap \theta q) \cap p \).

**Proof.** Given \( \beta \) choose a maximal subalgebra \( a \) containing \( \beta \) and a base \( \Pi \subseteq \Delta(g, a) \) such that \( \beta \) lies in the closure of the positive Weyl chamber. Then \( g^{\beta+} = q_I \) with \( I := \{ \lambda \in \Pi : \lambda(\beta) = 0 \} \). This proves the first assertion. To prove the second fix a parabolic subalgebra \( q \) and set \( \Omega := \{ \beta \in p : g^{\beta+} = q \} \). Let \( a \) be any maximal subalgebra of \( p \) contained in \( q \). Then \( q = q_I \) for some \( I \subseteq \Pi \) and
\[ (5) \] \[ \Omega \cap a = \{ \beta \in a_I : \lambda(\beta) > 0 \text{ for } \lambda \in \Pi - I \}. \]
Thus \( \Omega \cap a \) is a nonempty open convex cone in \( a_I \). Therefore \( \Omega \neq \emptyset \), which proves the second assertion. By \( \bigoplus_{I} a_I = z(q \cap \theta q) \cap p \), so \( \Omega \cap a \) is an open convex cone in \( z(q \cap \theta q) \cap p \). Moreover for any \( \beta \in \Omega \), \( a \subset q \cap \theta(q) = g^{\beta} \). Thus \( [\beta, a] = 0 \), hence \( \beta \in a \). So \( \Omega \subset a \), i.e. \( \Omega = \Omega \cap a \). \( \square \)

A parabolic subgroup of \( G \) is a subgroup of the form \( Q = N_G(q) \) where \( q \) is a parabolic subalgebra of \( g \). Equivalently, a parabolic subgroup of \( G \) is a
isometry of $u$

Let $\mu$ be the Kähler metric associated to $\omega$ on $X$. There exists a neighborhood of $0$ such that $\exp$ is a diffeomorphism on $\Omega$. If $\gamma \in g$, we can assume that
\[
\langle \exp X, \gamma \rangle = \langle \exp(\exp(t\beta)g) \exp(-t\beta), \gamma \rangle = e
\]
Note that $g^{\beta+} = g^\beta \oplus r^{\beta+}$.

**Lemma 2.9.** $G^{\beta+}$ is a parabolic subgroup of $G$ with Lie algebra $g^{\beta+}$. Every parabolic subgroup of $G$ equals $G^{\beta+}$ for some $\beta \in p$. $R^{\beta+}$ is the unipotent radical of $G^{\beta+}$ and $G^\beta$ is a Levi factor.

**Proof.** It is easy to check that $G^{\beta+}$ is a subgroup and that $G^{\beta+} = (G^G)^{\beta+} \cap G$. Therefore it is enough to prove that $(G^G)^{\beta+}$ is parabolic. In other words we can assume that $G$ is a complex reductive group. If $X \in g$, then
\[
\exp(t\beta) \exp X \exp(-t\beta) = \exp(\Ad(\exp(t\beta)) \cdot X) = \exp(e^{t\ad \beta} \cdot X)
\]
where $e^{t\ad \beta}$ denotes the exponential in $\End(g)$. Let $\Omega \subset g$ be a neighborhood of $0$ such that $\exp$ is a diffeomorphism on $\Omega$. If $X \in \Omega$, then $\exp X \in R^{\beta+}$ if and only if $\lim_{t \to -\infty} e^{t\ad \beta} \cdot X = 0$ if and only if $X \in r^{\beta+}$. This shows that $R^{\beta+}$ is locally closed, hence closed [13, Prop. 2.11 p. 119].

Next observe that if $g \in G^{\beta+}$, and
\[
a := \lim_{t \to -\infty} \exp(t\beta)g \exp(-t\beta)
\]
then $a \in G^G \subset G^{\beta+}$ and $a^{-1}g \in R^{\beta+}$. Therefore $G^{\beta+}$ is the product of the two closed subgroups $G^G$ and $R^{\beta+}$ and $G^G \cap R^{\beta+} = \{e\}$. It follows that $G^{\beta+}$ is a Lie subgroup of $G$ tangent to $g^{\beta+}$. Since we are now assuming that $G$ is complex, then it is well-known that $G^{\beta+}$ is closed and parabolic since its Lie algebra is parabolic. \hfill $\square$

### 2.4. Gradient momentum map.

Let $(Z, \omega)$ be a Kähler manifold. Assume that $U^G$ acts holomorphically on $Z$, that $U$ preserves $\omega$ and that there is a momentum map $\mu : Z \to u$. If $\xi \in u$ we denote by $\xi_Z$ the induced vector field on $Z$ and we let $\mu^\xi \in C^\infty(Z)$ be the function $\mu^\xi(z) := \langle \mu(z), \xi \rangle$. That $\mu$ is the momentum map means that it is $U$-equivariant and that $d\mu^\xi = i\xi_Z \omega$.

Let $G \subset U^G$ be compatible. If $z \in Z$, let $\mu_p(z) \in p$ denote $-i$ times the component of $\mu(z)$ in the direction of $i\xi$. In other words we require that $\langle \mu_p(z), \beta \rangle = -\langle \mu(z), i\beta \rangle$ for any $\beta \in p$. (Recall that multiplication by $i$ is an isometry of $u$ onto $iu$.) We have thus defined the gradient momentum map
\[
\mu_p : Z \to p.
\]

Let $\mu_p^\beta \in C^\infty(Z)$ be the function $\mu_p^\beta(z) = \langle \mu_p(z), \beta \rangle = \mu^{-i\beta}(z)$. Let $(\ , \ )$ be the Kähler metric associated to $\omega$, i.e. $(v, w) = \omega(v, Jw)$. Then $\beta_Z$ is the
gradient of $\mu_p^\beta$. If $X \subset Z$ is a locally closed $G$-invariant submanifold, then $\beta_X$ is the gradient of $\mu_p^\beta|_X$ with respect to the induced Riemannian structure on $X$.

**Theorem 2.2** (Slice Theorem [10, Thm. 3.1]). If $x \in X$ and $\mu_p(x) = 0$, there are a $G_x$-invariant decomposition $T_xX = g : x \oplus W$, open $G_x$-invariant subsets $S \subset W$, $\Omega \subset X$ and a $G$-equivariant diffeomorphism $\Psi : G \times G_x S \to \Omega$, such that $0 \in S$, $x \in \Omega$ and $\Psi([e, 0]) = x$.

Here $G \times G_x$ denotes the associated bundle with principal bundle $G \to G/G_x$.

**Corollary 2.1.** If $x \in X$ and $\mu_p(x) = \beta$, there are a $G^\beta$-invariant decomposition $T_xX = g^\beta : x \oplus W$, open $G^\beta$-invariant subsets $S \subset W$, $\Omega \subset X$ and a $G^\beta$-equivariant diffeomorphism $\Psi : G^\beta \times G_x S \to \Omega$, such that $0 \in S$, $x \in \Omega$ and $\Psi([e, 0]) = x$.

This follows applying the previous theorem to the action of $G^\beta$ with the momentum map $\hat{\mu}_w^{\beta} := \mu_{w^\beta} - i\beta$, where $\mu_{w^\beta}$ denotes the projection of $\mu$ onto $\mu_{w^\beta}$. See [10, p. 169] for more details.

If $\beta \in \mathfrak{p}$, then $\beta_X$ is a vector field on $X$, i.e. a section of $TX$. For $x \in X$, the differential is a map $T_xX \to T_{\beta(x)}(TX)$. If $\beta_X(x) = 0$, there is a canonical splitting $T_{\beta_X(x)}(TX) = T_xX \oplus T_xX$. Accordingly $d\beta_X(x)$ splits into a horizontal and a vertical part. The horizontal part is the identity map. We denote the vertical part by $d\beta_X(x)$. It belongs to $\text{End}(T_xX)$. Let $\{\varphi_t = \exp(t\beta)\}$ be the flow of $\beta_X$. There is a corresponding flow on $TX$. Since $\varphi_t(x) = x$, the flow on $TX$ preserves $T_xX$ and there it is given by $d\varphi_t(x) \in \text{Gl}(T_xX)$. Thus we get a linear $\mathbb{R}$-action on $T_xX$ with infinitesimal generator $d\beta_X(x)$.

**Corollary 2.2.** If $\beta \in \mathfrak{p}$ and $x \in X$ is a critical point of $\mu_p^\beta$, then there are open invariant neighbourhoods $S \subset T_xX$ and $\Omega \subset X$ and an $\mathbb{R}$-equivariant diffeomorphism $\Psi : S \to \Omega$, such that $0 \in S$, $x \in \Omega$, $\Psi(0) = x$. (Here $t \in \mathbb{R}$ acts as $d\varphi_t(x)$ on $S$ and as $\varphi_t$ on $\Omega$.)

**Proof.** The subgroup $H := \exp(\mathbb{R}\beta)$ is compatible. It is enough to apply the previous corollary to the $H$-action at $x$. \hfill \square

Assume now that $\beta \in \mathfrak{p}$ and that $x \in \text{Crit}(\mu_p^\beta)$. Let $D^2\mu_p^\beta(x)$ denote the Hessian, which is a symmetric operator on $T_xX$ such that

$$(D^2\mu_p^\beta(x)v, v) = \frac{d^2}{dt^2}(\mu_p^\beta \circ \gamma)(0)$$

where $\gamma$ is a smooth curve, $\gamma(0) = x$ and $\gamma'(0) = v$. Denote by $V_-$ (respectively $V_+$) the sum of the eigenspaces of the Hessian of $\mu_p^\beta$ corresponding to
negative (resp. positive) eigenvalues. Denote by $V_0$ the kernel. Since the
Hessian is symmetric we get an orthogonal decomposition
\begin{equation}
T_x X = V_- \oplus V_0 \oplus V_+.
\end{equation}

Let $\alpha : G \to X$ be the orbit map: $\alpha(g) := gx$. The differential $d\alpha_e$ is the
map $\xi \mapsto \xi_X(x)$.

**Proposition 2.1.** If $\beta \in \mathfrak{p}$ and $x \in \text{Crit}(\mu^\beta_p)$ then
\[ D^2 \mu^\beta_p(x) = d\beta_X(x). \]
Moreover $d\alpha_e(v^{\beta \pm}) \subset V_\pm$ and $d\alpha_e(g^\beta) \subset V_0$. If $X$ is $G$-homogeneous these are equalities.

**Proof.** The first statement is proved in \cite{10} Prop. 2.5]. Denote by $\rho : G_x \to T_x X$ the isotropy representation: $\rho(g) = dg_x$. Observe that $\alpha$ is $G_x$-equivariant where $G_x$ acts on $G$ by conjugation, hence $d\alpha_e$ is $G_x$-equivariant, where $G_x$ acts on $\mathfrak{g}$ by the adjoint representation and on $T_x X$ by the isotropy representation. Since $\beta_X(x) = 0$, $\exp(t\beta) \in G_x$ for any $t$ and $d\alpha_e$ is $\mathbb{R}$-equivariant. Therefore it interchanges the infinitesimal generators of the $\mathbb{R}$-actions, i.e. $d\alpha_e \circ \text{ad} = d\beta_X = D^2 \mu^\beta_p(x)$. The required inclusions follow. If $G$ acts transitively on $X$ we must have $T_x X = d\alpha_e(\mathfrak{g})$. Hence the three inclusions must be equalities. \hfill \Box

**Corollary 2.3.** For every $\beta \in \mathfrak{p}$, $\mu^\beta_p$ is a Morse-Bott function.

**Proof.** Let $X^\beta := \{x \in X : \beta_X(x) = 0\}$. Corollary \cite{2.2} implies that $X^\beta$ is
a smooth submanifold. Since $T_x X^\beta = V_0$ for $x \in X^\beta$, the first statement of Proposition \cite{2.1} shows that the Hessian is nondegenerate in the normal directions. \hfill \Box

### 2.5. Coadjoint orbits.

Let $U$ be a compact connected semisimple Lie group. Fix a scalar product $\langle \cdot, \cdot \rangle$ on $\mathfrak{u}$ and identify $\mathfrak{u}^* \cong \mathfrak{u}$. Let $z \in \mathfrak{u}$ and let
\[ Z := U \cdot z \quad \text{(adjoint action)}. \]
$Z$ is a (co)adjoint, hence it is provided with the Kostant-Kirillov-Sourian symplectic form which is defined by
\[ \omega(z,v) := \langle x, [v,w] \rangle \quad v, w \in \mathfrak{t}. \]
(See e.g. \cite{15} p. 5.) The inclusion $Z \hookrightarrow \mathfrak{u}$ is the momentum map for the $U$-action on $Z$. Set $Q := (U^\mathbb{C})^{\geq +}$. Then $Q$ is a parabolic subgroup of $U^\mathbb{C}$ and $T_z Z \cong \mathfrak{u}^\mathbb{C}/q$. This endows $Z$ with an invariant complex structure $J$ such that $\omega$ is an invariant Kähler form. Such a structure is in fact unique. The action of $U$ on $Z$ extends to a holomorphic action of $U^\mathbb{C}$.

To study $K$-orbits on $\mathfrak{p}$ it is convenient to identify $\mathfrak{p}$ with $i\mathfrak{p}$ by multiplying by $i$. A $K$-orbit $O = K \cdot x \subset \mathfrak{p}$ is mapped to $K \cdot ix \subset Z := U \cdot ix$. Since $G \subset U^\mathbb{C}$, $G$ acts on $Z$ and we have $G \cdot ix = K \cdot ix$, see \cite{11} Lemma 5 for
the case $G^C = U^C$ and [12, Prop. 6] for the general case. Therefore the data $G, K, U, Z, X$ are like in the previous setting. And identifying $O \cong K \cdot ix$, the gradient momentum becomes the inclusion $O \subset p$.

3. Face structure

3.1. Faces as orbitopes. Let $U$ be a compact Lie group and let $G \subset U^C$ be a compatible connected subgroup.

**Definition 3.1.** An orbitope of $G$ is the convex envelope of a $K$-orbit in $p$.

**Lemma 3.1.** We have $\text{ext } \hat{O} = O$ and $\text{ext } F = F \cap O$ for any face $F$ of $\hat{O}$.

**Proof.** This fact is common to all orbitopes, see [22, Prop. 2.2] or [2, Lemma 14].

We start the analysis of the structure of the faces of $\hat{O}$ by considering the exposed faces. At the end of §3.2 we will prove that in fact all faces of $\hat{O}$ are exposed. Let $\beta$ be a nonzero vector in $p$. Since $\mu_p$ is the inclusion $O \hookrightarrow p$, the function $\mu_\beta$ is $\mu_\beta(x) := \langle x, \beta \rangle$. Set

$$\text{Max}(\beta) := \{x \in O : \mu_\beta(x) = \max_{\hat{O}} \mu_\beta\}.$$  

The main result about this set is the following.

**Proposition 3.1.** The set $\text{Max}(\beta)$ is a connected $K^\beta$-orbit. In particular it is a $(K^\beta)^0$-orbit.

This theorem goes back to [6, 8]. Since it is basic we repeat the proof in our context. If $a \subset p$ is a maximal subalgebra, we denote by $W = W(t, a)$ the Weyl group of $a$ in $K$.

**Lemma 3.2.** Let $g$ be a real semisimple Lie algebra with Cartan decomposition $g = k \oplus p$ and let $a \subset p$ be a maximal subalgebra. If $x, y \in a$ then there is a Weyl chamber $C$ such that $\overline{C}$ contains both $x$ and $y$ if and only if $\lambda(x) \lambda(y) \geq 0$ for every restricted root $\lambda$.

**Proof (see [8, p. 11]).** A Weyl chamber is a connected component of the set where all roots are nonzero. Given such a component $C$, let $\Delta_+$ be the set of roots that are positive on $C$. Then $\Delta = \Delta_+ \sqcup (-\Delta_+)$. From this follows the “only if” part. To prove the “if” part we can assume that $x$ and $y$ are different. Let $z := (x + y)/2$ and let $C$ be a Weyl chamber with $z \in \overline{C}$. By assumption, no root changes its sign on the segment $[x, y]$. Therefore $\lambda(z) > 0$ implies that $\lambda(x) \geq 0$ and $\lambda(y) \geq 0$. If $\lambda(z) = 0$, then $\lambda(x) = \lambda(y) = 0$. Therefore $x$ and $y$ belong to $\overline{C}$. We thank the referee for pointing out this short argument. □
Lemma 3.3. Let $C \subset a$ be a Weyl chamber and let $x, y \in \overline{C}$. If $x' \in W \cdot x$, then there is a Weyl chamber $C'$ such that $x', y \in \overline{C'}$ if and only if there is $w \in W$ such that $w \cdot x = x'$ and $w \cdot y = y$.

Proof. The “if” part follows from the definition of a Weyl chamber. Assume the existence of a Weyl chamber $C'$ such that $x', y \in \overline{C'}$. Then $x' = \sigma x$ for some $\sigma \in W$. Let $w \in W$ be such that $w(C) = C'$. The points $w^{-1}x' = w^{-1}\sigma x \in a$ and $x$ belong to $\overline{C}$ and to the same Weyl orbit. Hence $w^{-1}x' = w^{-1}\sigma x = x$ [14, p. 52], i.e. $x' = wx$. Also $w^{-1}y$ and $y$ belong to $\overline{C}$. Hence also $wy = y$. This concludes the proof. □

Proposition 3.2. Let $G$ be a real connected semisimple Lie group. Let $\beta \in p$.

a) If $a \subset p^\beta$ is a maximal subalgebra, then

$$p^\beta = \bigcup_{k \in (K^\beta)^0} \text{Ad}(k)a.$$ 

b) Let $W^\beta := \{w \in W : w\beta = \beta\}$. Then for any $w \in W^\beta$ there is a $k \in (K^\beta)^0$ such that $\text{Ad}(k)a = a$ and $\text{Ad}(k)x = w \cdot x$ for every $x \in a$.

For a proof see for example [16, p. 378-9, 383, 455-7]).

Lemma 3.4. Crit($\mu_\beta^p$) = $\mathcal{O} \cap p^\beta$.

Proof. Let $Z$ be the $U$-orbit containing $\mathcal{O}$ as in §2.5. As observed in §2.4 grad $\mu_\beta^p = \beta_Z|_{\mathcal{O}}$. So the set of critical points of $\mu_\beta^p$ on $\mathcal{O}$ is the set of zeros of $\beta_Z$ on $Z$ intersected with $\mathcal{O}$. Since $(i\beta)_Z(x) = [i\beta, x]$, we have Crit($\mu_\beta^p$) = $\mathcal{O} \cap p^\beta$. □

Lemma 3.5. Let $G$ be semisimple. Fix $x \in \text{Crit}(\mu_\beta^p)$. Let $a \subset p$ be a maximal subalgebra containing both $x$ and $\beta$. Then

$$\text{Crit}(\mu_\beta^p) = \bigcup_{w \in W} (K^\beta)^0 \cdot w \cdot x = (K^\beta)^0 \cdot N_K(a) \cdot x,$$

where $W = W(\mathfrak{k}, a)$ is the Weyl group.

Proof. Let $z \in \text{Crit}(\mu_\beta^p) = \mathcal{O} \cap p^\beta$. By Proposition 3.2 there is $k \in (K^\beta)^0$ such that $k \cdot z \in a$. But $k \cdot z \in \mathcal{O}$ and $\mathcal{O} \cap a = W \cdot x$. □

Proposition 3.3. Let $G$ be semisimple. Assume that $x \in \mathcal{O} \cap a$ and $\beta \in a$. Then $x$ is a local maximum of $\mu_\beta^p$ if and only if there exists a Weyl chamber $C \subset a$ such that $x, \beta \in \overline{C}$. 

Proof. Let $\Delta$ be the set of restricted roots of $(\mathfrak{g}, \mathfrak{a})$ and let $\xi = \xi_0 + \sum_{\lambda \in \Delta} \xi_\lambda$ with $\xi_\lambda \in \mathfrak{g}_\lambda$. Fix a set of positive roots $\Delta_+$ such that $\lambda(x) \geq 0$ for every $\lambda \in \Delta_+$. We have

$$\mathfrak{k} = \mathfrak{h}(\mathfrak{a}) \oplus \bigoplus_{\lambda \in \Delta_+} (\mathfrak{g}_\lambda \oplus \mathfrak{g}_{-\lambda}) \cap \mathfrak{k}.$$  

(See e.g. [16, p. 370].) Since $T_x \mathcal{O} = \mathfrak{k} \cdot x = [\mathfrak{k}, x]$ and $[x, \mathfrak{g}_\lambda] = \mathfrak{g}_\lambda$ if $\lambda(x) \neq 0$ and $[x, \mathfrak{g}_\lambda] = 0$ otherwise, we have

$$T_x \mathcal{O} = \bigoplus_{\lambda(x) > 0} (\mathfrak{g}_\lambda \oplus \mathfrak{g}_{-\lambda}) \cap \mathfrak{p}.$$  

If $w \in T_x \mathcal{O}$, choose $\xi \in \mathfrak{k}$ such that $w = \xi_{\mathcal{O}}(x) = [\xi, x]$ and set $\gamma(t) := \text{Ad}(\exp(t\xi)) \cdot x$. Then $\gamma(0) = x$, $\dot{\gamma}(t) = [\xi, \gamma(t)]$, $\ddot{\gamma}(0) = [\xi, [\xi, x]]$ and

$$D^2 \mu_\beta(x)(w, w) = \frac{d}{dt} \bigg|_{t=0} \mu_\beta(\gamma(t)) = \langle \ddot{\gamma}(0), \beta \rangle = -\langle [\xi, x], [\xi, \beta] \rangle.$$  

We can assume that $\xi = \sum_{\lambda(x) > 0} \xi_\lambda$ with $\xi_\lambda \in \mathfrak{g}_\lambda$. This determines $\xi$ uniquely. Then

$$[x, \xi] = \sum_{\lambda(x) > 0} \lambda(x) z_\lambda$$  

where $z_\lambda = \xi_\lambda - \xi_{-\lambda}$. Since $\xi \in \mathfrak{k}$, $\theta(\xi_\lambda) = \xi_{-\lambda}$ and $z_\lambda \in \mathfrak{p}$. Moreover the vectors $z_\lambda$ are orthogonal to each other. Similarly $[\beta, \xi] = \sum_{\lambda(x) = 0} \lambda(\beta) z_\lambda$. So

$$D^2 \mu_\beta(x)(w, w) = -\sum_{\lambda(x) > 0} \lambda(x) \lambda(\beta) |z_\lambda|^2.$$  

If there is $\lambda \in \Delta_+$ such that $\lambda(x) \lambda(\beta) < 0$, then $x$ is not a local maximum point. Otherwise the Hessian is negative semidefinite and $D^2 \mu_\beta(x)(w, w) = 0$ if and only if $z_\lambda \neq 0 \Rightarrow \lambda(\beta) = 0$. This means that the kernel of $D^2 \mu_\beta(x)$ is $\mathfrak{t}^\beta \cdot x = T_x \text{Crit}(\mu_\beta)$. So the Hessian is degenerate only along the critical submanifold and is negative definite in the transverse direction. It follows that $x$ is a local maximum point. Summing up we have shown that $x$ is a local maximum point of $\mu_\beta$ if and only if $\lambda(x) \lambda(\beta) \geq 0$ for every $\lambda \in \Delta$. By Lemma 3.2 this is equivalent to the condition that $x$ and $\beta$ lie in the closure of some Weyl chamber. The result follows. \qed

Proof of Proposition 3.1. We start assuming that $G$ is semisimple. Let $E$ be the set of all local maxima of $\mu_\beta$. Since the function $\mu_\beta$ is $K^\beta$-invariant, the sets $E$ and $\text{Max}(\beta)$ are $K^\beta$-invariant. Since $\mathcal{O}$ is compact there is at least a point $x \in \text{Max}(\beta)$. Let $a \subset \mathfrak{p}$ be a maximal subalgebra containing $x$ and $\beta$. If $y \in E$, then by Lemma 3.5 there are $a \in (K^\beta)^0$ and $\tilde{w} \in W(\mathfrak{g}, a)$
such that \( y = a \cdot \tilde{w} \cdot x \). Since \( y \in E \), also \( \tilde{w} \cdot x \in E \). By Proposition 3.3 there are Weyl chambers \( C, C' \subset a \) such that \( x, \beta \in C \) and \( w \cdot x, \beta \in C' \).

By Lemma 3.3 there is \( w \in W \) such that \( w \cdot x = \tilde{w} \cdot x \) and \( w \cdot \beta = \beta \). By Proposition 3.2 there is \( k \in (K^\beta)^0 \) such that \( w \cdot x = k \cdot x \). It follows that \( y \in (K^\beta)^0 \cdot x \). So \( E \subset (K^\beta)^0 \cdot x \). Since \( (K^\beta)^0 \cdot x \subset \text{Max}(\beta) \subset E \) we conclude that \( E = \text{Max}(\beta) = (K^\beta)^0 \cdot x \). In particular \( \text{Max}(\beta) \) is connected because it is an orbit of a connected group. Since \( \text{Max}(\beta) \) is \( K^\beta \)-stable we also have \( \text{Max}(\beta) = K^\beta \cdot x \). If \( G \) is not semisimple, then split \( g = z \oplus [g, g] \) with \( z = z(g) \). Accordingly \( p = z \cap p \oplus p_{ss}, \mathfrak{k} = \mathfrak{k} \cap z \oplus \mathfrak{f}_{ss} \). Since \( K \) is connected, \( K = (Z(G) \cap K)^0 \cdot K_{ss} \). If \( O = K \cdot x \) split \( x = x_0 + x_1 \) with \( x_0 \in z \cap p \) and \( x_1 \in p_{ss} \). Then \( O = x_0 + O_1 \) where \( O_1 = K_{ss} \cdot x_1 \). If \( \beta \in p \), split \( \beta = \beta_0 + \beta_1 \) with \( \beta_0 \in p \cap z \) and \( \beta_1 \in p_{ss} \). Then \( \text{Max}(\beta) = x_0 + \text{Max}(\beta_1) \).

By Lemma 2.7 (b) \( G_{ss} \) is a semisimple compatible subgroup of \( U^\mathfrak{c} \) and \( O_1 \) is a \( K_{ss} \)-orbit in \( p_{ss} \). Therefore we know that \( \text{Max}(\beta_1) \) is connected and that it is an orbit of both \( (K_{ss}^\beta)^0 \) and \( K_{ss}^\beta \). Since \( K^\beta = (Z(G) \cap K) \cdot K_{ss}^\beta \), we conclude that \( \text{Max}(\beta) \) is a connected orbit of \( K^\beta \). Therefore it is also an orbit of \( (K^\beta)^0 \).

**Corollary 3.1.** Let \( \beta \) be a nonzero vector in \( p \) and let \( F_\beta(\hat{O}) \) be the exposed face of \( \hat{O} \) defined by \( \beta \), see (1). Then \( \text{ext} F_\beta(\hat{O}) = \text{Max}(\beta) \), \( F_\beta(\hat{O}) \subset p^\beta \) and \( \text{ext} F_\beta(\hat{O}) \) is both a \( K^\beta \)- and \( (K^\beta)^0 \)-orbit.

**Proof.** By Lemma 3.4 \( \text{ext} F_\beta(\hat{O}) = O \cap F_\beta(\hat{O}) = \text{Max}(\beta) \). Since \( \text{Crit}(\mu^\beta) = O \cap p^\beta \), we see that \( F_\beta(\hat{O}) \subset p^\beta \). By Proposition 3.1 \( \text{ext} F_\beta(\hat{O}) = \text{Max}(\beta) \) is an orbit of \( (K^\beta)^0 \).

**Proposition 3.4.** Let \( F \) be a nonempty face of \( \hat{O} \). Then there is an abelian subalgebra \( s \subset p \) such that \( F \) is an orbitope of \( (G^s)^0 \), i.e. \( F \subset \mathfrak{s}(s) \) and \( \text{ext} F \) is an orbit of \( (K^s)^0 \). If \( F \) is proper, then \( s \neq \{0\} \).

**Proof.** Fix a chain of faces \( F = F_0 \subsetneq F_1 \subsetneq \cdots \subsetneq F_k = \hat{O} \), such that for any \( i \) there is no face strictly contained between \( F_{i-1} \) and \( F_i \). This is possible by Lemma 2.5. We will prove the result by induction on \( k \). If \( k = 0 \), then \( F = \hat{O} \), so it is enough to set \( s = \{0\} \). Let \( k > 1 \) and assume that the theorem is proved for faces contained in a maximal chain of length \( k - 1 \). Fix \( F \) with a maximal chain as above of length \( k \). By the inductive hypothesis the theorem holds for \( F_1 \), so there is a nontrivial abelian subalgebra \( s_1 \subset p \) such that \( F_1 \subset p^{s_1} \) and \( \text{ext} F_1 \) is an orbit of \( (K^{s_1})^0 \). In other words \( F_1 \) is an orbitope of \( (G^{s_1})^0 \), which is a compatible subgroup by Lemma 2.7 (c).

Since \( F \) is a maximal face of \( F_1 \), it is exposed. There is \( \beta \in p^{s_1} \) such that \( F = F_\beta(F_1) \). Set \( s = s_1 \oplus \mathbb{R} \beta \). By Corollary 3.1 \( F \subset (p^s)^\beta = p^s \) and \( \text{ext} F \) is an orbit of \( ((K^{s_1})^\beta)^0 = (K^s)^0 \). Thus the inductive step is completed. If
$s = \{0\}$, then $(K^x)^0 = K$, $\text{ext } F = \mathcal{O}$ and $F = \hat{\mathcal{O}}$. So for proper faces $s \neq \{0\}$.

3.2. All faces are exposed. Let $G \subset U^C$ be a compatible subgroup and let $\mathcal{O}$ be a $K$-orbit in $p$. In general $\text{dim } \mathcal{O}$ might be less than $\text{dim } p$ and there might be some normal subgroup of $K$ that acts trivially on $\mathcal{O}$. We wish to describe a decomposition of $G$ that is useful in dealing with this degeneracy. Let $A$ be the affine hull of $\mathcal{O}$. This is an affine subspace of $p$ and we can write $A = x_0 + p_1$, where $p_1 \subset p$ is a linear subspace and $x_0 \in p$. If we impose that $x_0 \perp p_1$, then $x_0$ is uniquely determined. It follows that $x_0$ is fixed by $K$. Hence by Lemma 2.7, $x_0 \in \text{relint } \hat{\mathcal{O}}$. So also

$$
\mathfrak{t}_1 := [p_1, p_1], \quad p_0 = p_1^\perp, \quad \mathfrak{t}_0 = \mathfrak{t}_1^\perp, \quad g_1 := \mathfrak{t}_1 \oplus p_1, \quad g_0 := \mathfrak{t}_0 \oplus p_0.
$$

Thus $\mathfrak{t} = \mathfrak{t}_0 \oplus \mathfrak{t}_1$ and $p = p_0 \oplus p_1$ and $g = g_0 \oplus g_1$.

**Proposition 3.5.** $g_1$ is a semisimple ideal of $g$ and $g_0$ is a reductive ideal. If $G_1, K_0, K_1$ are the corresponding analytic (connected) subgroups, then $G_1$ is compatible with $U^C$ and $K^0 = K_0 \cdot K_1$. If $x \in \mathcal{O}$, then $x = x_0 + x_1$ for some $x_1 \in p_1$ and $\mathcal{O} = x_0 + K_1 \cdot x_1$.

**Proof.** Since $\mathcal{O}$ is a $K$-orbit, its affine hull is $K$-invariant. Therefore $x_0$ is fixed by $K$ and $[\mathfrak{t}, p_1] \subset p_1$. It follows that $[\mathfrak{t}, \mathfrak{t}_1] = [\mathfrak{t}, [p_1, p_1]] = [p_1, [p_1, \mathfrak{t}]] \subset [p_1, p_1] = \mathfrak{t}_1$. Since $[\mathfrak{t}, p_1] \subset p_1$ and $[\mathfrak{t}, \mathfrak{t}_1] \subset \mathfrak{t}_1$ also $[\mathfrak{t}, p_0] \subset p_0$ and $[\mathfrak{t}, \mathfrak{t}_0] \subset \mathfrak{t}_0$. Moreover $\langle [p_1, p_0], \mathfrak{t} \rangle = B([p_1, p_0], \mathfrak{t}) = B(p_0, [\mathfrak{t}, p_1]) \subset B(p_0, p_1) = 0$. (B is the bilinear form defined at the end of 2.7). Since $[p_1, p_0] \subset \mathfrak{t}$ this means that $[p_1, p_0] = 0$. Using the Jacobi identity we get also $[p_0, \mathfrak{t}_1] = [p_0, [p_1, p_1]] = [p_1, [p_1, p_0]] = 0$. Set $g_1 := \mathfrak{t}_1 \oplus p_1$. We have just showed that $g_1$ is an ideal of $g$. Since it is $\theta$-invariant, $g_1$ is a reductive subalgebra. We claim that it is semisimple. $\mathfrak{t}_1 \subset \mathfrak{g}_1 \mathfrak{g}_1$, so $\mathfrak{z}(g_1) \subset p_1$. Pick $x \in \mathcal{O}$. We can split $x = x_0 + x_1 + x_2$ where $x_0$ is as above, $x_2 \in \mathfrak{z}(g_1) \cap p_1$, $x_1 \in p_1$ and $x_1 \perp \mathfrak{z}(g_1)$. It follows that $\mathcal{O} = x_0 + x_2 + K \cdot x_1$, so the affine hull of $\mathcal{O}$ is $x_0 + x_2 + p_1 \cap \mathfrak{z}(g_1)^\perp$. Therefore $x_2 = 0$ and $p_1 \cap \mathfrak{z}(g_1)^\perp = p_1$, i.e. $\mathfrak{z}(g_1) = \{0\}$. This proves that $g_1$ is semisimple. Let $G_1 \subset G$ the (connected) analytic subgroup tangent to $g_1$. It is normal, closed [16, p. 440] and compatible by Lemma 2.7(e). The $B$-orthogonal complement of $g_1$ is $\mathfrak{t}_0 \oplus p_0$, which is also an ideal. So $K = K_0 \cdot K_1$ where $K_1 = G_1 \cap U$ and $K_0$ is the analytic subgroup of $K$ tangent to $\mathfrak{t}_0$. Since $K_0$ and $K_1$ are normal commuting subgroups $K_0$ acts trivially on $p_1$. Hence $\mathcal{O} = x_0 + K_1 \cdot x_1$. □

This decomposition can be further refined by setting $g_2 := [g_0, g_0]$ and $g_3 := \mathfrak{z}(g) = \mathfrak{z}(g_0)$. They are both $\theta$-invariant ideals of $g$, $g_2$ is semisimple and

$$
(7) \quad g = g_1 \perp g_2 \perp g_3.
$$
Set $p_i := g_i \cap p$ and $t_i := g_i \cap \mathfrak{t}$. At the group level $K^0 = K_1 \cdot K_2 \cdot K_3$, where $K_i$ are the corresponding analytic (connected) subgroups. Since $K \cdot x_0 = x_0$, $x_0 \in g_3$.

Let $a \subset p$ be a maximal subalgebra. Let $\pi : p \to a$ denote the orthogonal projection. Set

$$P := \pi(O).$$

The following convexity theorem of Kostant [18] is the basic ingredient in the whole theory.

**Theorem 3.1** (Kostant). Let $x \in a \cap O$. Then $P = \text{conv}(W \cdot x)$. In particular, $P$ is a convex polytope, $\text{ext} P = O \cap a$ and $\text{ext} P$ is a $W$-orbit.

The original proof of Kostant assumes that $G$ is semisimple. One easily reduces to that case using Proposition 3.5. The theorem can be proved within the framework of the gradient momentum map [9, Rmk. 5.4]. Another approach is by observing that the orbits of polar representations are isoparametric submanifolds. Terng [25] has proved a convexity theorem for isoparametric submanifolds, which in the case of polar orbits gives the original statement by Kostant. See also [21]. The following lemma is a consequence of Kostant convexity theorem. See [7, Lemma 7] for a proof.

**Lemma 3.6.** (i) If $E \subset p$ is a $K$-invariant convex subset, then $E \cap a = \pi(E)$.
(ii) If $A \subset a$ is a $W$-invariant convex subset, then $K \cdot A$ is convex and $\pi(K \cdot A) = A$.

**Proposition 3.6.** Let $F$ be a face of $\hat{O}$. Choose a subalgebra $s \subset p$ such that $F$ is an orbitope of $(G^s)^0$. Let $a$ be a maximal subalgebra of $p$ containing $s$. Set $\sigma := \pi(\text{ext} F)$. Then $\sigma = \pi(F) = F \cap a$ and $\sigma$ is a nonempty face of the polytope $P$. If $F$ is proper, then $\sigma$ is proper. $F$ is an orbitope of $(G^\sigma)^0$, where $\sigma^\perp \subset a$ denotes the orthogonal to the tangent space of $\sigma$. Moreover $\text{ext} F$ is an orbit of $K^{\sigma^\perp}$ and $F = K^{\sigma^\perp} \cdot \sigma$.

**Proof.** The set $\text{ext} F$ is an orbit of $(K^s)^0$ and $a \subset g^s$. By Kostant theorem $\pi(\text{ext} F) = \text{conv}(\text{ext} F \cap a)$ and $\text{ext} F \cap a$ is an orbit of the Weyl group $W = W(g^s, a)$. So $\sigma$ is convex. Fix $x \in \text{ext} F \cap a$. Since $\pi$ is linear, $\pi(F) \subset \text{conv}(\pi(\text{ext} F)) = \sigma$. On the other hand $\text{ext} \subset W \cdot x = (\text{ext} F) \cap a$. Hence $\sigma \subset F \cap a$. And obviously $F \cap a \subset \pi(F)$. Summing up $\pi(F) \subset \sigma \subset F \cap a \subset \pi(F)$. The first assertion is proved. That $\sigma$ is a face of $P$ follows directly from Lemma 2.6 while $\sigma = \pi(F) \neq \emptyset$ since $F \neq \emptyset$. To check the other assertions observe that $\text{ext} F$ is an orbit of $(K^s)^0$, so that we can apply Proposition 3.5 to this orbit. We get a semisimple normal subgroup $G_1$ of $(G^s)^0$, a decomposition $g^s = g_1 \oplus g_2 \oplus g_3$ like (7) and compact subgroups $K_1, K_2, K_3 = Z(K^s)^0$ such that $(K^s)^0 = K_1 \cdot K_2 \cdot K_3$. It follows that
Moreover, the restriction of $\pi$ to $p_1$ is the orthogonal projection $p_1 \rightarrow a_1$ and the affine hull of $\sigma$ is $x_0 + a_1$. Hence $\sigma^\perp = a_2 \oplus p_3$. $g_1$ is semisimple and centralizes. Thus $s \subset \sigma^\perp$, $K^\sigma^+ \subset K^s$ and $(K^\sigma^+)^0 = K_1 \cdot K_3$. So $K_1 \subset K^\sigma^+ \subset K^s$ and $K_1 \cdot x \subset K^\sigma^+ \cdot x \subset K^s \cdot x$. Since $K_1 \cdot x = K^s \cdot x = \text{ext } F$ we get that $\text{ext } F$ is an orbit of $K^\sigma^+$. But $\text{ext } F$ is connected, so it is also an orbit of $(K^\sigma^+)^0$. Since $\sigma^\perp = a_2 \oplus p_3$, $x_0 + p_1 \subset p_3 \oplus p_1 = p^\sigma^+$. This shows that $F$ is an orbitope of $(G^\sigma^+)^0$. We have to prove that $F = K^\sigma^+ \cdot \sigma$. Since $K_2$ acts trivially on $x_0 + p_1$, $K^\sigma^+ \cdot \sigma = K^s \cdot \sigma$. Since $F$ is $K^s$-invariant, we get $K^\sigma^+ \cdot \sigma \subset F$. On the other hand $\text{ext } F \subset K^s \cdot \sigma$. Since $\sigma$ is $W$-invariant we can apply Lemma 3.6 (with $K = K^s$ and $p = p^s$) to get that $K^s \cdot \sigma$ is convex. Therefore we get $F = K^s \cdot \sigma = K^\sigma^+ \cdot \sigma$. It remains to prove that $\sigma$ is proper, when $F$ is proper. Assume first that the affine hull $\hat{O}$ is $p$. Then the affine hull of $P$ is $a$. If $F$ is proper, then $s \neq \{0\}$, so $a_1 \subseteq a$ and $\sigma \subseteq P$. In the general case, we have to apply Proposition 3.5 this time to $\hat{O}$ rather than $\text{ext } F$. $\hat{O}$ turns out to be a translate of an orbitope of a semisimple subgroup of $G$ by an element of the center of $g$. $a$ splits into the center of $g$ and a maximal subalgebra of the semisimple subgroup. With this we easily reduce to the case we have just considered.

Corollary 3.2. Let $F_1, F_2$ be proper faces of $\hat{O}$, and let $s_1, s_2 \subset p$ be subalgebras such that $F_i$ is a $(G^s)^0$-orbitope. Assume that $a \subset p$ is a maximal subalgebra containing both $s_1$ and $s_2$. If $F_1 \cap a = F_2 \cap a$, then $F_1 = F_2$.

Proof. If $\sigma := F_1 \cap a$, then $F_1 = K^\sigma^+ \cdot \sigma = F_2$.

Theorem 3.2. All proper faces of $\hat{O}$ are exposed.

Proof. Given a proper face $F \subset \hat{O}$ choose a subalgebra $s \subset p$ such that $F$ be a $(G^s)^0$-orbitope and choose a maximal subalgebra $a \subset p$ containing $s$. By Proposition 3.6 $\sigma := F \cap a$ is a proper face of $P$. Since all faces of a polytope are exposed [21, p. 95], there is a vector $\beta \in a$ such that $\sigma = F_\beta(P)$. Since $\beta \in a$ and $P = \pi(O)$, $h_P(\beta) = \max_{x \in O} \langle \beta, x \rangle = h_\partial(\beta)$. Set $F' := F_\beta(\hat{O})$. We wish to show that $F = F'$. The inclusion $F \subset F'$ is immediate: if $x \in F$, then $\pi(x) \in \sigma$, so $\langle x, \beta \rangle = h_P(\beta) = h_\partial(\beta)$. It is also immediate that $F' \cap a = \sigma$. So we have two faces $F$ and $F'$ with $F \cap a = F' \cap a = \sigma$. Set $s' := \mathbb{R} \beta \subset a$. By Corollary 3.1, $F'$ is an orbitope of $(G^s)^0$. Applying Corollary 3.2 we get $F = F' = F_\beta(\hat{O})$.

Corollary 3.3. If $O' \subset O$ is a smooth submanifold, then $\text{conv}(O')$ is a face of $\hat{O}$ if and only if there is a vector $\beta$ such that $O' = \text{Max}(\beta)$. 
Denote by $C$ set Proposition 3.7. For any face faces and parabolic subgroups. 3.3. Let $\lambda$ proper, then the group $I$ by $V$. Assume that Lemma 3.7. Let $\beta$ given any $\beta$. So we should have $\beta, \xi$ constant. We prove first that $C, H_F = K^\beta$. By Lemma 3.1 $F \subset p^\beta$. Then $F \subset p^\beta$ and $\lambda$ stable. We have Proposition 3.8. If $F \subset C$ is a proper face, and $\beta \in CF^F$, then $Q_F = G^\beta +$. Proof. We prove first that $G^\beta + \subset Q_F$, i.e. that $G^\beta +$ preserves $\lambda$. Since $\beta \in CF^F$, $H_F = K^\beta$. In general $G^\beta +$ will not be connected. Nevertheless
$K \cap G^{\beta+} = K^\beta$ meets all components of $G^{\beta+}$. By Proposition 3.7, $K^\beta = H_F \subset Q_F$. So it is enough to prove that $(G^{\beta+})^0 \subset Q_F$. This amounts to showing that for any $\xi \in g^{\beta+}$ the vector field $\xi_0$ is tangent to $x$. Fix an arbitrary $x \in ext F$. Since $F = F_\beta(\hat{O})$, ext $F =$ Max$(\beta)$, so $x$ is a maximum point of $\mu_\beta$, hence $V_+ = \{0\}$ in (6). By Proposition 2.1 $d\alpha_e(g^{\beta+}) = d\alpha_e(g^d) + d\alpha_e(t_+^\beta) \subset V_0 + V_+ = V_0$. Hence for any $\xi \in g^{\beta+}$, $\xi_0(x) = d\alpha_e(\xi) \in V_0 = T_x$ ext $F$. Thus we proved that $G^{\beta+} \subset Q_F$. We also know that $G^{\beta+} \cap K = K^\beta = H_F = Q_F \cap K$. Also, $Q_F \subset G$ is a closed subgroup, hence a Lie subgroup. Thus we can apply Lemma 3.7 to the Lie algebras of $G^{\beta+}$ and $Q_F$ respectively, and we obtain $g^{\beta+} = q_F$. Therefore $Q_F \subset N_G(q_F) = G^{\beta+}$. And thus the theorem is proved. □

**Proposition 3.9.** The set $\{ext F : F$ a nonempty face of $\hat{O}\}$ coincides with the set of all closed orbits of parabolic subgroups of $G$. Any parabolic subgroup $Q \subset G$ has a unique closed orbit, which equals the set of extreme points of a unique face of $F \subset \hat{O}$. If $Q = G^{\beta+}$, then $F = F_\beta(\hat{O})$.

**Proof.** Let $Q \subset G$ be parabolic. There is at least one closed orbit since the action is algebraic. Choose $\beta \in p$ such that $Q = G^{\beta+}$. Then $K^\beta = Q \cap K$. Let $O'$ be any closed orbit of $Q$ and let $x \in O'$ be a maximum point of $\mu_\beta$ over $O'$. Since the gradient of $\mu_\beta$ at $x$ is $\beta_0(x)$ and $\beta \in g^{\beta+}$, we get $\beta_0(x) = 0$. By Proposition 2.1 $d\alpha_e(g^{\beta+}) = V_0 \oplus V_+$, so $V_+ \subset T_x(G^{\beta+} \cdot x) = T_x O'$. Since $x$ is a maximum point of $\mu_\beta$ over $O'$, we conclude that $V_+ = \{0\}$. Thus $x$ is a local maximum point of $\mu_\beta$ and $R^{\beta+}$ acts trivially on $O'$. But $\mu_\beta$ has only global maxima, hence $x \in$ Max$(\beta)$ and $O' = G^{\beta} \cdot x = K^\beta \cdot x =$ Max$(\beta)$. Set $F = F_\beta(\hat{O})$. Then $O' = ext F$. This proves that the closed orbit is unique. □

**Corollary 3.4.** For any face $F$ we have $C^H_F = \{\beta \in p : G^{\beta+} = Q_F\}$.

**Proof.** By Proposition 3.3 the set on the left is included in the set on the right. Conversely, if $\beta$ is in the set on the right, then $\beta \in C_F$ with $F = F_\beta(\hat{O})$, by the previous Theorem. Since $H_F = Q_F \cap K = G^{\beta+} \cap K = K^\beta$, $\beta$ is also fixed by $H_F$. □

If $F$ is a proper face set

(8) \[ s_F := \text{span}(C^H_F) \quad G_F := Q_F \cap \theta(Q_F). \]

If $\beta \in C^H_F$, then $G_F := G^\beta$.

**Corollary 3.5.** $s_F$ is an abelian subalgebra of $p$ and $s_F = \mathfrak{z}(g_F) \cap p$.

**Proof.** $s_F$ is the span of $C^H_F$ and $g_F = q_F \cap \theta q_F$. Thus the result follows from Corollary 3.4 and Lemma 2.8 □
Corollary 3.6. \( H_F = K^g \) and \( G_F = G^g \).

Proof. It follows from the discussion in the proof of Lemma 2.8, that the vectors of \( C_F^{H_F} \) are regular in \( s_F = a_I \), i.e. if a root vanishes on \( \beta \in C_F^{H_F} \), then it vanishes on the whole of \( s_F \). Thus \( K^g = K^\beta \) and \( G^g = G^\beta \). \( \square \)

Corollary 3.7. The face \( F \) is an orbitope of \( G_F^0 \).

Proof. If \( \beta \in C_F^{H_F} \), then \( F \) is a \((G^\beta)^0\)-orbitope by Corollary 3.1 \( \square \)

Corollary 3.8. Let \( F \) be a face and let \( a \subset p \) be a maximal subalgebra. Then \( C_F^{H_F} \cap a \neq \emptyset \) if and only if \( C_F^{H_F} \subset a \) if and only if \( a \subset g_F \).

Proof. If \( \beta \in C_F^{H_F} \cap a \), then \([\beta, a] = 0 \). Since \( \beta \) is regular in \( s_F \), we get \( s_F \subset a \). Conversely, if \( s_F \subset a \), then \( C_F^{H_F} \subset a \). Since \( g_F = g^s_F \) the condition \( s_F \subset a \) is equivalent to \( a \subset g_F \). \( \square \)

3.4. Proof of Theorem 1.1. Fix a maximal subalgebra \( a \subset p \). Denote by \( \mathcal{F}(\hat{O}) \) the set of proper faces of \( O \) and by \( \mathcal{F}(P) \) the set of proper faces of the polytope \( P \). If \( F \) is a face of \( O \) and \( a \subset K \), then \( a \cdot F \) is still a face, so \( K \) acts on \( \mathcal{F}(\hat{O}) \). Similarly \( W = W(\gamma, a) \) acts on \( \mathcal{F}(P) \). We wish to show that \( \mathcal{F}(\hat{O})/K \cong \mathcal{F}(P)/W \).

Lemma 3.8. For every face of \( \hat{O} \) there is a \( a \subset K \) such that \( s_{a, F} \subset a \). The face \( a \cdot F \) is unique up to \( N_K(a) \).

Proof. By Theorem 3.2 \( F = F_\gamma(\hat{O}) \) and \( H_F = K^\gamma \) for some \( \gamma \in p \). Choose \( a \subset K \) such that \( \text{Ad}(a) \gamma \subset a \). Then \( a \cdot F = F_{\text{Ad}(a) \gamma}(\hat{O}) \). Therefore \( \text{Ad}(a) \gamma \) belongs to \( C^{H_F}_{a,F} \) and also to \( a \). By Corollary 3.6 \( s_{a,F} \subset a \). To prove the second statement it is enough to show that \( F = F_\gamma(\hat{O}) \) with \( \gamma \in a \) and \( \text{Ad}(a) \gamma \subset a \), then there is \( g \in N_K(a) \) such that \( g \cdot F = a \cdot F \). Since \( \gamma \in a \cap \text{Ad}(a^{-1})a \), both \( a \) and \( \text{Ad}(a^{-1})a \) are maximal subalgebras in \( p^\gamma \). Hence there is \( g \in K^\gamma = H_F \) such that \( \text{Ad}(a^{-1})a = \text{Ad}(g)a \). Therefore \( w := ag \in N_K(a) \) and \( a \cdot F = ag \cdot F = w \cdot F \). \( \square \)

Define a map
\[ \varphi : \mathcal{F}(\hat{O})/K \to \mathcal{F}(P)/W \]
by the following rule: given a class in \( \mathcal{F}(\hat{O})/K \) choose a representative \( F \) such that \( s_F \subset a \) and set \( \varphi([F]) := [F \cap a] \). By Proposition 3.3 \( F \cap a \) is indeed a face of the polytope and by Lemma 3.8 a different choice of the representative will yield the same class in \( \mathcal{F}(P)/W \), so that the map \( \varphi \) is well-defined.

Now fix a face \( F \) with \( s_F \subset a \). \( F \) is an orbitope of \( G_F^0 \). Applying Proposition 3.5 we get a decomposition \( g_F = g_1 \oplus g_2 \oplus g_3 \) like \( (7) \). Here \( g_3 = \mathfrak{z}(g_F) \).
Let $F$ assume that both $s\phi$ is the identity. Thus $\phi := F\phi$. Theorem 1.1. Consequently $x = \phi(x)$ for $x \in \mathfrak{g}_{\mathfrak{p}}$. By Lemma 3.9 $\mathfrak{p}$ is equal to the $\mathfrak{h}$ Lemma 3.10. Accordingly $\mathfrak{u}$ is any vector $\mathfrak{v}$ fixes $\sigma$ pointwise and the statement follows.

If $\sigma$ is a face of $P$ set $G_\sigma := \{g \in W : g(\sigma) = \sigma\}$. Lemma 3.10. If $\sigma \in \mathcal{F}(P)$ there is a vector $\beta \in \mathfrak{a}$ that is fixed by $G_\sigma$ and such that $\sigma = F_\beta(P)$. If $\beta$ is any such vector and $F := F_\beta(\hat{O})$, then $F \cap \mathfrak{a} = \sigma, G_\sigma = W_1 \times W_2, \mathfrak{s}_F = \mathfrak{a}^{G_\sigma}$ and $F$ depends only on $\sigma$, not on the choice of $\beta$.

Proof. The existence of a $G_\sigma$-invariant $\beta$ such that $F_\beta(P) = \sigma$ follows directly from Lemma 3.9. If $F := F_\beta(\hat{O})$ it follows immediately that $F \cap \mathfrak{a} = \sigma$.

By Lemma 3.9 $W_1 \times W_2 \subset G_\sigma$, so $\beta \in \mathfrak{a}^{G_\sigma} \subset \mathfrak{a}^{W_1 \times W_2} = \mathfrak{s}_F$. It follows that $H_F = K^{\beta}$. The subgroup of $W$ that fixes $\beta$ is the Weyl group of $(\mathfrak{g}_{\mathfrak{p}}, \mathfrak{a})$ i.e. $W_1 \times W_2$. Hence $W_1 \times W_2 = G_\sigma$ and $\mathfrak{s}_F = \mathfrak{a}^{G_\sigma}$. So $\mathfrak{s}_F$ depends only on $\sigma$, not on the choice of $\beta$. The same holds for $H_F = K^{\mathfrak{s}_F}$ and for ext $F$, which is equal to the $H_F$-orbit through a point in ext $\sigma$.

Define a map $\psi : \mathcal{F}(P)/W \to \mathcal{F}(\hat{O})/K$ by the following rule: given $\sigma$, fix $\beta \in \mathfrak{a}^{G_\sigma}$ such that $\sigma = F_\beta(P)$ and set $\psi([\sigma]) := [F_\beta(\hat{O})]$. By the previous lemma $F_\beta(\hat{O})$ depends only on $\sigma$, not on $\beta$. It is clear that $\psi$ is well-defined on equivalence classes.

Theorem 1.1. The maps $\psi$ and $\varphi$ are inverse to each other. Therefore $\mathcal{F}(P)/W$ and $\mathcal{F}(\hat{O})/K$ are in bijective correspondence.

Proof. Let $\sigma$ be a face of $P$. Choose $\beta \in \mathfrak{a}^{G_\sigma}$ such that $\sigma = F_\beta(P)$. If $F := F_\beta(\hat{O})$, then $\mathfrak{s}_F \subset \mathfrak{a}$. So $\varphi \circ \psi([\sigma]) = \varphi([F]) = [F \cap \mathfrak{a}] = [\sigma]$ and $\varphi \circ \psi$ is the identity. Thus $\varphi$ is surjective. It is enough to show that $\varphi$ is injective. Let $F_1, F_2 \subset \hat{O}$ be faces such that $\varphi([F_1]) = \varphi([F_2])$. Acting with $K$ we can assume that both $\mathfrak{s}_{F_1}$ and $\mathfrak{s}_{F_2}$ are contained in $\mathfrak{a}$. Acting with $W$ we can also assume that $F_1 \cap \mathfrak{a} = F_2 \cap \mathfrak{a}$. By Corollary 3.2 we get $F_1 = F_2$. By
Proposition 3.6 the map between $\mathcal{F}(P)/W$ and $\mathcal{F}(\hat{O})/K$ is the one stated in the introduction. □

Remark 3.1. Let $K_1 \to O(V)$ be a polar representation. By Dadok’s theorem there is a semisimple Lie group $G$ with Cartan decomposition $g = \mathfrak{k} \oplus \mathfrak{p}$ such that $V = \mathfrak{p}$ and the orbits of $K_1$ coincide with the orbit of $\text{Ad} K$. A maximal subalgebra $\mathfrak{a} \subset \mathfrak{p}$ is a section for both actions. Denote by $W$ the Weyl group of $(g, \mathfrak{a})$ and by $W_1$ the Weyl group of the polar representation of $K_1$. If $x \in \mathfrak{a}$, then $W \cdot x = K \cdot x \cap \mathfrak{a} = K_1 \cdot x \cap \mathfrak{a} = W_1 \cdot x$. We claim that $F(\hat{O})/K_1 = F(\hat{O})/K$ and $F(P)/W_1 = F(P)/W$. Indeed let $F \in F(\hat{O})$ and $k \in K$. Fix a point $x \in \text{relint } F$. There is some $k_1 \in K_1$ such that $k_1 x = k x$. Then $k x$ belongs both to $\text{relint } kF$ and to $\text{relint } k_1 F$. Hence $kF = k_1 F$ by Theorem 2.1. This shows that the $K$-orbit through $F$ is contained in the $K_1$-orbit through $F$. Interchanging $K$ and $K_1$ we get the opposite inclusion. Thus $F(\hat{O})/K_1 = F(\hat{O})/K$. In the same way one proves that $F(P)/W_1 = F(P)/W$. From this it follows that Theorem 1.1 holds for any polar representation.

4. Final remarks

It follows from the results in the previous section that there are a finite number of $K$-orbits on the set $F(\hat{O})$. Given such an orbit, we denote by $S$ the union of the faces in the orbit. Therefore $S$ equals $K \cdot F$ for some face $F \in F(\hat{O})$. We call $S$ the stratum corresponding to the face $F$. Arguing as in the case of coadjoint orbitopes [2, §5] one proves the following.

Theorem 4.1. The strata give a partition of $\partial \hat{O}$. They are smooth embedded submanifolds of $\mathfrak{p}$ and are locally closed in $\partial \hat{O}$. For any stratum $S$ the boundary $\overline{S} - S$ is the disjoint union of strata of lower dimension.

The computation of the dimension of the strata is trickier in this case. Nevertheless the bound in the statement follows easily from the following argument. If $E$ is an $n$-dimensional convex body, then $\partial E$ has Hausdorff dimension $n - 1$. If $F$ is an $n$-dimensional face, the boundary of the stratum $S := K \cdot F$ is a fiber bundle over a compact base with fibres isometric to $\partial F$. Therefore its Hausdorff dimension is strictly smaller than the dimension of $S$.

Also the description of the faces of $\hat{O}$ and of the momentum polytope in terms of root data is just as in the case of coadjoint orbitopes (see §6 in [2]). We briefly state the result.

Fix a maximal subalgebra $\mathfrak{a}$ of $\mathfrak{p}$ and a system of simple roots $\Pi \subset \Delta = \Delta(\mathfrak{g}, \mathfrak{a})$. A subset $E \subset \mathfrak{a}$ is connected if there is no pair of disjoint subsets $D, C \subset E$ such that $D \sqcup C = E$, and $\langle x, y \rangle = 0$ for any $x \in D$ and for any
$y \in C$. (A thorough discussion of connected subsets can be found in [23], [20, §5].) Connected components are defined as usual. If $x$ is a nonzero vector of $a$, a subset $I \subset \Pi$ is called $x$-connected if $I \cup \{x\}$ is connected. Equivalently $I \subset \Pi$ is $x$-connected if and only if every connected component of $I$ contains at least one root $\alpha$ such that $\alpha(x) \neq 0$. If $I \subset \Pi$ is $x$-connected, denote by $I'$ the collection of all simple roots orthogonal to $\{x\} \cup I$. The set $J := I \cup I'$ is called the $x$-saturation of $I$. The largest $x$-connected subset contained in $J$ is $I$. So $J$ is determined by $I$ and $I$ is determined by $J$. Given a subset $I \subset \Pi$ we will denote by $Q_I$ the parabolic subgroup with Lie algebra $q_I$ as defined in [2].

**Theorem 4.2.** Let $O \subset p$ be a $K$-orbit and let $x$ be the unique point in $O \cap C$.

a) If $I \subset \Pi$ is $x$-connected and $J$ is its $x$-saturation, then $Q_I \cdot x = Q_J \cdot x$ and $F := \text{conv}(Q_J \cdot x)$ is a face of $\hat{O}$. If $\beta \in a_J$ and $\lambda(\beta) > 0$ for any $\lambda \in \Pi - J$, then $F = F_\beta(\hat{O})$. Moreover $Q_F = Q_J$.

b) Any face of $\hat{O}$ is conjugate to one of the faces constructed in (a).
