In this paper we show that there is a universal prediction for the Newtonian potential for a specific class of infinite derivative, ghost-free, quadratic curvature gravity. We show that in order to make such a theory ghost-free at a perturbative level, the Newtonian potential always falls-off as $1/r$ in the infrared limit, while at short distances the potential becomes non-singular. We provide examples which can potentially test the scale of gravitational non-locality up to 0.004 eV.

INTRODUCTION

Einstein’s theory of General Relativity (GR) has passed successfully through innumerable tests from small scales to large scales [1]. One of its predictions, of the existence of gravitational waves, has recently been confirmed by the advanced Laser Interferometer Gravitational-Wave Observatory (LIGO), which has observed a transient gravitational-wave (GW) signal and tested the reliability of GR [2]. In all these examples, in the infrared (IR), the theory matches the Newtonian fall of $1/r$ potential. In spite of these great successes, the theory of GR is incomplete in the ultraviolet (UV), the classical solutions of GR exhibit black hole and cosmological type singularities, and at a quantum level the theory is not UV finite. GR definitely requires modifications in the UV; the question is what kind of corrections in the UV one would expect, which would make the theory well behaved in the classical and in quantum sense, and possibly resolve the short distance singularities.

For a massless graviton, in 4 dimensions, all the interactions in the UV can in principle be captured by incorporating higher derivatives allowed by the diffeomorphism invariance. For instance, it is well-known that higher derivatives can ameliorate the UV behaviour, i.e. 4th derivative gravity is renormalisable, but at a cost of introducing a ghost term in the spin-2 component of a graviton propagator [3]. Indeed, the presence of ghosts can lead to a destabilising of the classical vacuum, therefore rendering the theory unpredictable at both classical and at a quantum level.

Recently, the issue of ghosts has been addressed in the context of quadratic gravity - in order to make the theory generally covariant and ghost-free at the perturbative level, one would require infinite derivatives [4,5]. Indeed, these infinite derivatives would modify the graviton propagator. However, if we capture the roots of these infinite derivatives by the exponential of an entire function, then there will be no new degrees of freedom propagating in spacetime other than the massless transverse and traceless graviton, since such modification of the graviton propagator would not introduce any new pole.

It has been demonstrated that these infinite derivatives with a graviton propagator modified by the exponential of an entire function can indeed soften the quantum UV behaviour [6,11]. Furthermore, such a prescription also removes the cosmological Big Bang singularity [6,12], and black hole type singularity in a static limit [4], and in the dynamical context [13], in a linearised limit. One intuitive way to understand this is due to the fact that infinite derivatives render the gravitational interactions non-local [6,11]. This non-locality also introduces an inherent new scale in 4 dimensions, i.e. $M \lesssim M_p \sim 2.4 \times 10^{18}$ GeV. Furthermore, an intriguing connection can be established between the gravitational entropy [14], and the propagating degrees of freedom in the spacetime. The gravitational entropy for ghost-free, infinite gravity does not get a contribution from the UV, but only from the Einstein-Hilbert action [15], and follows strictly the area - law for entropy for a Schwarzschild’s black hole.

The aim of this paper is two-fold: first we show that for a wide class of infinite derivative theories of gravity which are ghost-free, it is possible to recover not only the $1/r$ fall of the Newtonian potential in a static limit in the IR, but also to ameliorate the short distance behaviour in the UV limit. Second, we wish to put a bound on the scale of non-locality, i.e. $M$, from the current table-top experiments from deviation of Newtonian gravity.

QUADRATIC CURVATURE GRAVITATIONAL ACTION

Let us first start by discussing the properties of GR in 4 dimensions. The linearised GR can be quantised around the Minkowski background, which is described by 2 massless degrees of freedom. The transverse and traceless components of the graviton propagator in 4 dimensions can be recast in terms of the spin projector operators, which involves the tensor $P^{(3)}$, and only one
of the scalar components, i.e. \( P_s(0) \):\(^1\)

\[
\Pi(k^2) \sim \frac{1}{k^2} \left( P^{(2)} - \frac{1}{2} P_s^{(0)} \right),
\]

(1)

where \( k^\mu \) is the 4-momentum vector, where we have suppressed the spacetime indices.

In fact, in [4]\(^2\) it has been shown that around the Minkowski background, in 4 dimensions, the most general quadratic order torsion-free and parity invariant gravitational action which can be made ghost-free can be written in terms of the Ricci-scalar, \( R \), the symmetric traceless tensor, \( S_{\mu\nu} = R_{\mu\nu} - \frac{1}{2} R g_{\mu\nu} \), and \( C_{\mu\nu\alpha\beta} \) is the Weyl tensor. It is sufficient to study the quadratic order action - which captures \( O(h^2) \) terms around the Minkowski background, i.e. \( g_{\mu\nu} = \tilde{g}_{\mu\nu} + h_{\mu\nu} \), where \( \tilde{g}_{\mu\nu} \) is the Minkowski background, and \( h_{\mu\nu} \) are the excitations, in order to find the graviton propagator. The \( S \)-tensor vanishes on maximally symmetric backgrounds (Minkowski or (anti)-de Sitter)\(^3\) therefore the full action can be written as:

\[
S = \int d^4 x \sqrt{-g} \left[ \frac{M_P^2}{2} R + \frac{\lambda}{2} \left( R F_1(\Box) R \right. \right. \\
+ S_{\mu\nu} F_2(\Box) S^{\mu\nu} + C_{\mu\nu\lambda\sigma} F_3(\Box) C^{\mu\nu\lambda\sigma} \left. \left. \right) \right],
\]

(2)

where \( M_P^2 \) is the Planck mass, and \( \lambda \) is a dimensional coupling accounting for the higher curvature modification, and the \( F_i \) are Taylor expandable (i.e. analytic) functions of the covariant d’Alembertian [4], i.e. \( F_1(\Box) = \sum_{n=0} c_n \Box^n / M^{2n} \), where \( M \) is the scale of non-locality.

\[
\delta^2 S(\tilde{h}_{\mu\nu}) = \int d^4 x \sqrt{-g} \frac{1}{2} \tilde{h}_{\mu\nu} \Box a(\Box) \tilde{h}^{\mu\nu},
\]

\[
\delta^2 S(\phi) = - \int d^4 x \sqrt{-g} \frac{1}{2} \phi \Box c(\Box) \phi,
\]

for the tensor component (where the field was rescaled by \( M_P / 2 \) to become canonically normalised), and the scalar component (where the field was rescaled by \( M_P \sqrt{3/32} \) to be canonically normalised), respectively.

The full graviton propagator can then be written using a similar method to [10], barring the suppressed indices\(^4\).

\[\text{UNIVERSALITY OF THE NEWTONIAN POTENTIAL}\]

Physical excitations of this action, Eq. (2), around Minkowski background have been studied very well. This can be computed by the second variation of the action, using \( g_{\mu\nu} = \tilde{g}_{\mu\nu} + h_{\mu\nu} \). A quick computation can be made by employing the covariant mode decomposition of the metric [21]:

\[
h_{\mu\nu} = \tilde{h}_{\mu\nu} + \nabla_\mu A_\nu + \nabla_\nu A_\mu + (\nabla_\mu \nabla_\nu - \frac{1}{4} g_{\mu\nu} \Box) B + \frac{1}{4} g_{\mu\nu} h,
\]

(3)

where \( \tilde{h}_{\mu\nu} \) is the transverse and traceless spin-2 excitation, \( A_\mu \) is a transverse vector field, and \( B, h \) are two scalar degrees of freedom which mix. Upon linearization around maximally symmetric backgrounds, the vector mode and the double derivative scalar mode vanish identically, and we end up only with \( \tilde{h}_{\mu\nu} \) and \( \phi = h - \Box B \).

Performing necessary computations (which are indeed straightforward around Minkowski as all derivatives commute), one gets [17]:

\[
a(\Box) = 1 + \frac{\lambda}{M_P^2} \Box \left( F_2(\Box) + 2 F_3(\Box) \right)
\]

\[
c(\Box) = 1 - \frac{\lambda}{M_P^2} \Box \left( 6 F_1(\Box) + \frac{1}{2} F_2(\Box) \right)
\]

(4)

\[\text{dices [17] [19] [22]}:
\]

\[
\Pi(k^2) = \frac{P^{(2)}}{k^2 a(-k^2)} + \frac{P^{(0)}}{k^2 (a(-k^2) - 3 c(-k^2))},
\]

(5)

where \( P^{(2)}, (0) \) are the spin projection operators [10]. Note that the graviton propagator has two unknown functions \( a(k^2) \) and \( c(k^2) \), where all the information about the infinite derivatives is hiding, see [10] [19] [22].

\[\text{In [10], the authors imposed 6 projection operators to decompose spin 2 and spin 0 component of the propagator, here we have employed a slightly different technique to decompose the 10 metric degrees of freedom.}\]
for an alternative way of deriving the graviton propagator, Eq. [5], and related discussion on form factors. It is possible that \(a(\mathcal{O})\) and \(c(\mathcal{O})\) are not uniquely defined under field redefinitions \([7, 9]\), but this is beyond the scope of this paper.

In order to reduce the graviton propagator to that of GR, one method is to assume that \(a(\mathcal{O}) = c(\mathcal{O})\). In the IR limit then both \(a(k^2 \to 0) = 1\), \(c(k^2 \to 0) = 1\), such that Eq. [5] reduces to Eq. [3]. In this limit the theory would match exactly GR’s predictions in the IR, but would lead to modification in the UV. The entire modification can be summarised by one unknown function \(a(\mathcal{O})\), which constrains the functions such that, see for instance \([19]\):

\[
12\mathcal{F}_1(\mathcal{O}) + 6\mathcal{F}_2(\mathcal{O}) + 4\mathcal{F}_3(\mathcal{O}) = 0.
\]

In order that the propagator have no poles except the massless graviton at \(k = 0\), we require that \(a(\mathcal{O})\) and \((a(\mathcal{O}) - 3c(\mathcal{O}))\) must not contain any zeros. This way the propagator, Eq. [5], will not contain any extra degrees of freedom propagating in the space-time other than the massless graviton with 2 helicity states. One possible choice is to assume \(a(\mathcal{O})\) is the exponential of an entire function \(\tau\), i.e. \(\tau\), where \(\tau\) is the mass of a massless graviton with 2 helicity states. One possible example will be \([4, 5, 7]\):

\[
a(\mathcal{O}) = c(\mathcal{O}) = e^{-\mathcal{O}/M^2}.
\]

This choice guarantees that in the UV the theory is softened, as for \(k \to \infty\), \(a(-k^2) = c(-k^2) = e^{k^2/M^2}\) suppresses the propagator in the UV, i.e. \(\Pi(k^2) \to 0\) in Eq. [5], while \(k \to 0\) yields the pure 4D GR propagator.

Our aim in this paper will be to generalise this to any entire function \(\tau(-k^2)\), such that in the momentum space we have:

\[
a(-k^2) = c(-k^2) = e^{-\tau(-k^2/M^2)}.
\]

The computation of the Newtonian potential, i.e. \(\Phi(r)\), for the simplest choice, when \(\tau(-k^2/M^2) = -k^2/M^2\) as in Eq. [6], was done already in \([5]\), and the result is

\[
\Phi(r) \sim -\frac{\mu}{4\pi^2 M^2 r} \sqrt{\frac{\pi}{2}} \text{erf}(Mr/2),
\]

where \(\mu\) is the mass of a \(\delta\)-source. This potential is finite near \(r \approx 0\) and decays as \(1/r\) at distances above the non-locality scale, i.e. \(r \gg M^{-1}\). The tests of \(1/r\) fall of Newtonian gravity has been tested in the laboratory up to \(5.6 \times 10^{-5}\) m \([23]\), which implies that for the scale of non-locality should be bigger than \(M > 0.004\) eV. Indeed, we know very little about the gravitational interaction above this limit! The cornerstone of this computation is the sine Fourier transform

\[
f(r) = \int_{-\infty}^{+\infty} \frac{dk}{k} e^{i(kr)} \sin(kr),
\]

where

\[
\Phi(r) = -\frac{\mu}{4\pi^2 M^2} \frac{1}{r} \int_{-\infty}^{+\infty} \frac{dk}{k} e^{i(kr)} \sin(kr).
\]

When we consider the simplest choice, \(\tau = -k^2/M^2\), the function \(f(r)\) indeed gives an erf-function.

We now set out to prove that the leading behaviour of the potential at small distances, \(r\), away from the source is always given by: \(\Phi = \Phi_0 + O(r)\), where \(\Phi_0\) is constant irrespectively of the form of an entire function \(\tau(k^2)\), as long as it does not introduce any extra pole other than the massless graviton.

**GENERALISATIONS OF THE ENTIRE FUNCTION**

Note that for an entire function, we can always treat \(f(r)\) as a polynomial function. As a warm-up exercise we note that the sine Fourier transformation for

\[
\tau = -\frac{k^{2n}}{M^{2n}},
\]

gives

\[
f(r) = \frac{M_r}{n} \sum_{p=0}^{\infty} (-1)^p \frac{\Gamma\left(\frac{p}{2} + \frac{1}{2}\right)}{(2p + 1)!} (Mr)^{2p},
\]

using the Gamma function \(\Gamma(x) \equiv (x-1)!\). The above result is a generalisation of \([24]\), where the authors have analysed special cases for \(n = 1, 2, 4\). From Fig. 1 we see that the Newtonian potential never blows up at \(r = 0\).

An important observation here is that by increasing the value of \(n\) yields larger modulation for large \(r\), giving us a clear deviation from predictions of GR at larger distances, and providing us with a glimpse of testing the non-locality scale \(M\). We can see that by having higher modes we now switch on a new mechanism that can be falsifiable in a near-future experiment.

Tests of the inverse square-law assume that departure from the Newtonian potential follows a Yukawa potential,

\[
V(r) = -V_0 \left[1 + \alpha \exp(-r/\lambda)\right],
\]

In \([23]\), Adelberger et al. found in 2007 that this potential was ruled out for \(\alpha = 1\) down to a length scale of \(5.6 \times 10^{-5}\) m, which means that we can now constrain \(M\) for each \(\tau(-k^2)\).

For each specific value of \(n\) in Eq. [12], we can check for what value of \(M\) that our potential would be detectable by \([23]\). The experiment ruled out a Yukawa potential \(V(r) = V_0/r[1+\exp(-r/5.6 \times 10^{-5})]\) down to length scales of \(5.6 \times 10^{-2}\) m. Since this Yukawa potential is already ruled out, if a particular value of the scale of non-locality

\[\text{footnote}{Although further tests have been carried out, such as in \([25]\), none of these give a stronger constraint on } r \text{ for } \alpha = 1.\]
or using Hermitian polynomials $H_n(x)$ as
\[ f(r) = -2\sqrt{\pi} e^{-\frac{r^2}{4}} \sum_{m=1}^{\infty} \rho_m (-1)^m \frac{1}{4^m} H_{2m-1} \left( \frac{Mr}{2} \right). \]
Note that Eq. (16) converges to a constant if $\rho_m$ decreases at least as fast as $\frac{(-1)^m}{m!}$, i.e. $\rho = -k^2/M^2$.

In order to satisfy the low energy requirements of the underlying physics, we require that the function $e^{\tau(-k^2)}$ falls at least as fast as $e^{-k^2/M^2}$ \[^4\]. Any $e^{\tau(-k^2)}$ which does this will also fulfill the convergence condition for Eq. (16), meaning that any physically realistic $a(\square)$ will give a Newtonian potential which returns to the GR $1/r$ potential in the IR limit.

Next, in order to graphically show the behaviour of Eq. (16) in Fig. 2, we take the next simplest case, where $\tau$ is the binomial
\[ \tau = -\frac{k^2}{M^2} - \frac{a_N k^{2N}}{M^{2N}}, \]
and the choice of $a_N$ is motivated by the purpose of illustration of the oscillations that occur for $r \approx M^{-1}$. In this case,
\[ \rho_m = \frac{(-a_N)^{m/N}}{(m/N)!} \text{ for } \frac{m}{N} \in \mathbb{N} \text{ and zero otherwise.} \]
orders of magnitude, i.e. $0.004 \text{ eV} \leq M \leq 10^{18} \text{ GeV}$, but this window also provides an opportunity for testing gravity at short distances.
