Abstract

Background Domestic violence in pregnancy is a severe public health problem. Victimized pregnant women are confronted with the threats posed by domestic violence. Pregnancy and protection of the unborn child could affect maternal strategies for managing violence. The purpose of this study was to explore Iranian women's strategies for managing domestic violence in pregnancy.

Methods This was a qualitative descriptive study, which was conducted in October 2019 to June 2021 in Mashhad, Iran. Data were collected through individual semi-structured interviews with 13 women who experienced perinatal domestic violence, two relatives and 24 related specialists as well as two focus group discussion with attendance of 20 victimized mothers until the data saturation was achieved. Data were analyzed by the conventional content analysis approach of Graneheim & Lundman.

Results The main themes “adopting escape strategies” and “applying situation improvement strategies” were emerged as the result of data analysis. Adopting escape strategies was comprised of three categories including concealment, passive dysfunctional behaviors and neutral behaviors to control maternal emotional distress. Applying situation improvement strategies was comprised of three categories including active self-regulation, protecting family privacy and help seeking to control violence.

Conclusion Understanding the experience of managing domestic violence among pregnant women is essential to design evidence based violence prevention programs, which enable supportive healthcare and social systems to encourage victimized mothers to use more effective strategies and seeking help to overcome domestic violence.

Plain English Summary

Domestic violence during pregnancy threatens the health of mother and fetus. Mothers who experience domestic violence often use several strategies to decrease the violence. This study sought women's experiences in managing domestic violence during pregnancy.

13 women who experienced perinatal domestic violence, one daughter, one husband and 24 specialists as well as two focus group discussion with attendance of 20 abused mothers were interviewed in Mashhad in the north east of Iran.

The results showed abused mothers used adopting escape strategies and applying situation improvement strategies for managing domestic violence. Mostly abused mothers used emotion oriented strategies such as adopting escape strategies for managing violence. These strategies were included of concealment, passive dysfunctional behaviors and neutral passive behaviors. Some mothers with regard to individual decision-making and individual abilities tried to improve their situation by active self-regulation, protecting family privacy and help seeking. The results of these various strategies vary from reducing domestic violence to not changing the intensity of the violence or intensifying the perinatal domestic violence.

In conclusion; inappropriate strategies against domestic violence could be threatening for fetal and maternal life and should be considered in maternal education. Understanding the experience of domestic violence among these women is essential to design evidence based domestic violence prevention strategies and programs.

Introduction

Domestic violence is a public health concern and human rights violation affecting more than one third of all women in global (1). Domestic violence and intimate partner violence are frequently used interchangeably in the literature (2). It is estimated that one in three women disclose domestic violence during or after pregnancy, but prevalence differs depending on the location (3). The prevalence has been estimated from 3 to 30 percent (4) reaching 15% to 71% in low to middle-income countries (5). In relation to the literature the prevalence of domestic violence may increases during pregnancy, remains unchanged or decreases (6).

Despite the prominence of the dignity of the woman in the Islamic, there are different types of violence against women (7). The results of a review study conducted in Iran (2014) with an assessment of 38 articles showed that the prevalence of domestic violence in Iranian pregnant women varies from 19.3% to 94.5% (8).

Domestic violence during pregnancy threatens the health of mother and fetus and is a dangerous but preventable factor for many perinatal morbidity and mortality (9). These complications included isolation, reduce maternal social networks, inadequate pregnancy care, inadequate pregnancy related weight gain, vaginal bleeding, spontaneous abortion, preeclampsia, sexually transmitted infections, stress, reduced quality of life, dissatisfaction of pregnancy and drug and alcohol abuse. Other complications included stillbirth, prematurity, low birth weight, newborn complications, avoidance of breastfeeding, delayed mother infant bonding and maternal abusive behaviors toward their infants and children personality complications (10-16).

Women who experience domestic violence often use a variety of mental and behavioral strategies to inhibit or stop the violence (17, 18). Actually in the face of increasing violence, mothers often revealed increased activity in protecting themselves and their children.

Abused pregnant women who confront significant difficulties in keeping themselves and the unborn baby safe (19). Pregnancy can create a common sense of isolation that may be exaggerated by experiences of domestic violence and reduce maternal social networks (13). Social support provides the chance to discuss stressful experiences, receive support and reduced risk of suffering from domestic violence during pregnancy (20-22).

Coping is an essential strategy for managing domestic violence that include efforts to manage a problem through the continuous change of intellectual and behavioral efforts (23-25). In domestic violence situations, coping relate to resilience strategies that victims accomplish to minimize harm and handle the
situation (26). The two main forms of coping strategies in domestic violence conditions are problem focused and emotion focused coping (25, 27). The process of coping with domestic violence can be understood in relation with the social and cultural background, capacity and access to supportive resources and the severity of the violence (24).

The capability to inhibit and cope with violence is different for pregnant women compared to non-pregnant population (28, 29) and coping strategies are affected by adolescence and pregnancy (30). Abused pregnant women may use resilience through problem focused coping, adjusting their motherhood, expand levels of their social support and seeking help. (31). In spite of the increased risks associated with domestic violence during pregnancy, many women use their experiences effectively such as resilience (32). As domestic violence in pregnancy and coping with it has a close association with the social, regional and cultural contextual, it is essential to collect the associated information in various social and geographical contexts (33), so conducting the research in a certain local context can be the most important factor in better clarification and move toward resolving the problem of domestic violence.

Iranian Islamic society is a patriarchal society that highlights men's authority over women in the family (34-36). Wife's obedience to the husband, tolerate husband's violence and keeping the family are women's duties and considered honorable (36). Islam has highlighted the issue of family integrity and deems divorce is a lawful but undesirable and discouraged act (35). Women are defined by their roles as mothers or wives which expect them to sacrifice and put their husband's and children's needs ahead of their own to keep their family from breaking up (34). In such circumstances, abused pregnant women more likely attempt to adopt various strategies to strengthen their marital relationship and prevent from family breakup. In order to achieve a deeper understanding about the strategies for managing domestic violence during pregnancy, it is necessary to develop a qualitative study that reflects maternal behaviors and needs. Different qualitative studies on pregnant women's experiences with domestic violence were conducted in the world (37-39,30,19), but no evidence exist to explain the experiences of Iranian pregnant women with domestic violence and their strategies for managing domestic violence in pregnancy. Understanding the experience of domestic violence among these women is essential to design evidence based domestic violence prevention strategies and programs. To the best of our knowledge, this study would be the first one to explore Iranian women's strategies for managing domestic violence in pregnancy.

Methods

Design

Qualitative description was used as the study design to get direct description of maternal experience of managing domestic violence in pregnancy (40). Qualitative description is a valuable qualitative approach and recovered for health sciences research (41).

Setting

The current study was carried out from October 2019 to June 2021 in Mashhad, the capital of Khorasan Razavi Province, one of the most populous city in the north east of Iran. At first obstetrics and gynecology departments of teaching hospitals were used to select the participants. The reason for this selection were high referral of pregnant women and effective management of these departments. Theoretical sampling led to the selection of Comprehensive Health Center, Prenatal Clinic, Midwifery Counseling Center, Provincial Welfare Center, Forensic Medicine Center, Social Emergency, Consultant Voice Center, and other related organization as study setting.

Participants

Purposive sampling with maximum variation such as age, occupational status, education, number of marriage, gestational age, wanted or unwanted pregnancy and domestic violence screening score was used to select the participants. Data were collected through Individual semi structured interviews with 13 women who experienced perinatal domestic violence, one husband and one daughter and 24 key informant comprising of health care professionals as well as the specialists in reproductive health, social working, forensic medicine, psychology, law, sociology and media. Two focus group discussion with attendance of 20 victimized mothers were conducted because of their resistance to be interviewed individually. The participants' profile is shown in table 1 and 2.

Inclusion criteria were maternal agreement for participation in the study, their ability to communicate with the researcher, endorsing perinatal domestic violence and ability to share their related experiences. Exclusion criterion was maternal physical and mental disease that prevent their participation in the study.

Data collection

Semi structured and face to face interviews were used for the data collection by the first author with good experience of qualitative research and 20 years working experience in the field of reproductive health and midwifery. The interviews were accomplished at a time and place that was appropriate to participants and were audio recorded. The interviews continued until the data saturation. Data saturation was obtained following 37 interviews. However, to confirm data saturation, two further interviews were carried out which revealed no new data. An interview guide with open ended questions was used to explore participants' experiences as follows "Please describe your experience of violence during pregnancy or postpartum?" Other questions followed the main question were "How do you react when you are abused?", "How does pregnancy influence the managing skills you used?", "What are some of the ways you keep yourself and unborn baby safe?", and "what is your advice for other pregnant abused women and service providers?"

The interviews lasted between 30 and 120 minutes (mean: 65 min) and each focus group took approximately 90 minutes.

Data analysis
The study showed that abused mothers initially react to their husbands' violence by crying, getting angry, and even laughing. This quote reflects it:

1.2. a. Emotional release

...support. Usually they used passive dysfunctional behaviors for relief psychological complication as emotion focused strategies.

According to present study abused mothers knew they were being harmed by violence but remained in a relationship due to maternal commitment and lack of system and the legal community and in this manner they manage perinatal violence in their ways. One participant stated:

"In my opinion, all pregnant mothers are abused in some way, but they do not disclose it, they don't tell this situation to anyone. They hide violence."

Abused mothers were constantly confronted with the harms and threats posed by violence and had to deal with these harms in different ways. At first, they tried to reduce the psychological stress of violence in various ways such as concealment, passive dysfunctional behaviors and neutral behaviors without directly paying attention to reduce husband's violence.

1. Adopting escape strategies

Abused mothers were initially at a crossroads in choosing to disclose domestic violence or conceal violence. Mostly abused Iranian mothers concealed perinatal domestic violence despite the routine screening for domestic violence during prenatal care. They hid violence from family, friends, the health care system and the legal community and in this manner they manage perinatal violence in their ways. One participant stated:

"In my opinion, all pregnant mothers are abused in some way, but they do not disclose it, they don't tell this situation to anyone. They hide violence."

( Participant 10 – 36 years old- 1 year postpartum)

1.2. Passive dysfunctional behaviors

According to present study abused mothers knew they were being harmed by violence but remained in a relationship due to maternal commitment and lack of support. Usually they used passive dysfunctional behaviors for relief psychological complication as emotion focused strategies.

1.2. a. Emotional release

The study showed that abused mothers initially react to their husbands' violence by crying, getting angry, and even laughing. This quote reflects it:
"When he beats me I shout but he beats more. I cry so much. I can do nothing. What should I do?" (Participant 1 – 37 years old- 36 weeks of gestation)

1.2. b. Retaliatory behaviors

Some abused pregnant mothers utilized retaliation and defiance as emotion-focused coping strategies for dealing with domestic violence. Not submitting to the demands of husband, not talking, self-defense, immorality, fighting back were different ways to deal with violence, which had no effect on reducing violence and sometimes intensified husband's violence. The following quote reflects this:

"When my husband abuses me, I retaliate. I would answer everything he says. He wanted to kick me in the stomach. I stood in front of him, you know, my nail went into his hand and his hand was bleeding so my heart was cooled." (Participant 7 – 36 years old- 17 weeks of gestation)

1.2. c. Abuse to husband and child

In some participants trying to get rid of psychological distress could lead women to sexual disobedience, sexual ignorance and even in a few participants extramarital relationships and thoughts of killing their husbands. One participant stated:

"I got very upset when my husband bothered me. I made my bed and slept in another room. I did not allow him to have sex." (Participant 7 – 36 years old- 17 weeks of gestation)

Under the psychologic stress of perinatal domestic violence a few mothers hit the fetus, harassed their children, beat children and even leaved their children to decrease their distress. One participant declared:

"When I was angry, I would hit the baby in my stomach and empty myself in such a way. I beat the baby because there was no one else at home that I hit him/her to empty myself in that way." (Participant 5 – 25 years old- 10 hours postpartum)

1.2. d. Helplessness and confusion

Pregnancy and postpartum create a sense of isolation for mother that magnified by experiences of domestic violence. Inefficient self-talk, leave spirituality, inattention to herself, self-worthlessness, self-forgetfulness and wish for death were maternal strategy for dealing with emotional effect of perinatal domestic violence. One participant explained:

"I have not prayed for a long time. Previously, nothing could stop me from praying. But I stopped praying for a while now. I'm very sad. Every time I did not pray, I felt as if I lost something. I lost my way." (Participant 2 – 22 years old- 39 weeks of gestation)

1.2. e. Recourse to divorce

A few abused mothers achieved separation belief and decided to divorce as the final solution to get rid of their abusive husband when they could not find another way to reduce the violence. One mother said:

"If my husband's behavior had not changed and he continued to be violent, I would have separated from him, even with a child, because my child would be under more pressure in this stressful life." (Participant 11 – 36 years old- 1 year postpartum)

1.3. Neutral behaviors

The result of present study indicated that neutral passive behavior as placating strategies and diverting attention were of the common strategies used by abused mothers to minimize the recurrence and intensifying of violence in their marital relationships.

1.3. a. Placating strategies

Placating and acceptance of violence were recommended by most of participants as one of the best ways of minimizing the recurrence of perinatal domestic violence. Placating such as silence, tolerance, burning and building, patience, submission, obedience, indifference, waiver and violence normalization were of the best ways of keeping peace in the house. The following quote reflects it:

"A woman may face the worst insults and behaviors in her husband's house, but she must be silent. The man does whatever he wants, insults, disrespects ... but the woman should be quiet and calm at the house." (Focus group discussion- 35 years old- 1 year postpartum)

1.3. b. Diverting attention

Diverting attention from the issue of violence and forgetting and justification mechanism were another emotion focused maternal strategies for dealing with domestic violence. The following statement confirm this:

"Despite violent behaviors of my husband, I tried to calm down, I was involved with my baby in my womb. This made me not to think about violence." (Participant 2 – 22 years old- 39 weeks of gestation)

2. Applying situation improvement strategies

Some mothers, while believing in the necessity of covering up violence with regard to individual decision-making and individual abilities, and in the shadow of high self-esteem and self-confidence or by disclosure violence and seeking support tried to improve their situation by active self-regulation, protecting family
privacy and help seeking.

### 2.1. Active self-regulation

The result of present study indicated that maternal urge to protect the unborn baby and protect marital life were of the most important impetus for try to reduce violence by focus on it.

#### 2.1. a. Self-actualization

Some abused mothers used the maternal active strategies for dealing with domestic violence in order to be able to protect the privacy of the marital life without causing psychological harm. These strategies included create a good mood, self-relaxation, return attention through enjoyable activities, positive mental imagery and maintain authority, skills and empowerment. These quote reflects it:

“Every time my husband was beating me, the baby in my womb was in a bad mood, her movements were slowing down, but I was making fun of myself at home. I was entertaining myself. Sometimes I watched TV programs because of my fetus to see colorful pictures in my stomach and have a positive effect on her mood in this way. Every day, as soon as my husband left the house, I would do the housework and go for a walk with my children to calm down so that we would feel better.” (Participant 6 – 41 years old- 1 month postpartum)

#### 2.1. b. Comprehensive self-care skills

The mother acquired Comprehensive self-care skills through physical self-care, emotional psychological self-care, social self-care and spiritual self-care. The following statement approve this:

“I was prioritizing for myself. I made time for myself. I even went to the park so that the baby in my womb could hear the sound of the babies in the park. I was talking to her and I was saying that there is a park here, there is a slide, it is swinging, look how beautiful it is, the children are swinging, see what they are screaming and shouting. I controlled myself, I calmed myself down.” (Participant 6 – 41 years old- 1 month postpartum)

#### 2.1. c. Promoting positive self-concepts

Maintaining and promoting self-confidence, self-esteem and self-control are the strategies that the mother uses to promote positive self-concepts. The following statement confirm this:

“I see in my friends have lost their self-confidence during pregnancy. They think that their husband is no longer interested in them, because their appearance has become ugly and they have become fat so their situation is getting worse day by day. I never spoke in front of my husband that I was ugly during my pregnancy and after that. I always said I am very good in every way and I have no problems.” (Participant 11 – 36 years old- 1 year postpartum)

#### 2.1. d. Resilience

Despite the increased risks associated with domestic violence during pregnancy, many women effectively navigate their experiences and come to display adaptive outcomes, such as resilience. Resilience included promote individual growth, being purposeful, source of internal control, flexibility, independence, realistic look and thinking positive. One participant stated:

“I think a part of the husband's violence is because of economic issues. Some mothers understand the pressure on their husband in life. They think it is fair to tolerate verbal violence occasionally but no other types of physical, sexual and emotional violence, especially during pregnancy so that the fetus stays healthy and is not harmed.” (Focus group discussion- 38 years old- 6 months postpartum)

#### 2.1. e. Strengthening spirituality

Abused mothers endorsed strengthen spirituality as a form of adaptive coping strategy they adopted in dealing with perinatal domestic violence. Relying on God, appealing to the Imams and submitting to the divine destinies were strategies that formed based on the mother's religious beliefs and resulted in maintaining her peace and reducing her vulnerability and ultimately increasing the mother's ability to protect the privacy of the marital life. This quote reflects it:

“No one can help me. Only God can help. Only God can create an opening in our lives and improve our situation. Only Imam Reza can help.” (Participant 3 – 29 years old- 40 weeks of gestation)

### 2.2. Protecting family privacy

The result of present study showed that protecting family privacy by purposeful effort to correct spouse behavior, supportive efforts and maintain maternal commitment were the active maternal problem solving strategy for dealing with domestic violence.

#### 2.2. a. Constructive purposeful efforts

In the initial exposure to violence, some of the mothers tried to control violence by using purposeful effort to correct husband's behavior such as turn disputes into positive negotiation, building trust, create intimacy, promote husband information, maintain the authority of the husband, meet the sexual needs of the husband, encourage her husbands for psychological counseling and trying to change the destructive behavior of the husband. The following statements indicate it:
"I tried to maintain my husband's authority and I did not do anything without his information. When the fetal movement was reduced, I endured a lot of anxiety from morning to night, but because I had to coordinate with my husband and then left home, I didn't want to go to the hospital without my husband's information to control the fetal heart rate." (Participant 11 – 36 years old- 1 year postpartum)

2.2. b. Supportive efforts

Some mothers supported their husbands in economic and emotional status. Although supportive efforts did not reduce the husband's violence, it could improve the mother's psychological states and it affected the mother's sense of satisfaction with her ability and empowerment.

One educated mother stated: "I was teaching at university before I got pregnant, I had projects, I had some savings. I paid for my prenatal care and screening tests because I felt my husband was resisting paying for them, and I was so happy to be able to pay for perinatal care." (Participant 10 – 36 years old- 1 year postpartum)

2.2. c. Maintaining maternal commitment

The result of present study revealed that maternal commitment such as efforts to maintain fetal health, trying to keep the children calm and priority the comfort of the fetus and children to maternal liberation from violence made mother to stay in abusive relationship and didn't think about separation. In fact mothers sacrificed themselves and put their children's needs ahead of their own to keep their family from breaking up. One mother explained:

"When you become a mother, the feeling of motherhood makes you look at life differently, you are responsible for maintaining the health of your child, and the most important thing is to be patient and tolerant. Patience and endurance in the face of all the violence of the husband, for the sake of keeping the fetus healthy because of the duty of motherhood." (Participant 1 – 37 years old- 36 weeks of gestation)

2.2. d. Preserving marriage

Some abused mothers tried to save their marital life despite their husbands' violence because of their interest in cohabitation and their husband's satisfactory commitment. One participant stated:

"Although my husband sometimes abuses me, but my marital life is good. I love my life very much. I think my life is better than my sister's and my mom's. I love my husband. My husband is a man who has been standing on his own feet since he was 15 years old. I am very satisfied with my life, I do not want to lose my life." (Participant 5 – 25 years old- 10 hours postpartum)

2.2. e. Avoiding social judgments

Avoiding social isolation and preventing the stigma of divorce, the stigma of remarriage, preventing the lack of financial support after divorce and the lack of a supportive family prompted the abused mother to try to protect the privacy of the marital life. One participant described:

'I was born and raised in a small town. If a woman divorces, society and her family look at her with pity and her life will destroyed. These are the things that make a mother stay under any circumstances and try to save her common life.' (Focus group discussion- 28 years old- 35 weeks of gestation)

2.3. Help seeking

The result of study revealed that some abused mothers finally tried to generate solutions by disclosure violence and gain formal and informal support.

2.3. a. Disclosure of violence

Some abused mothers finally disclosed domestic violence following the failure of previous strategies used and the intensification of violence. Maternal empowerment and familiarity with individual rights, the ability of the health care system to identify violence, the presence of supportive families and supportive systems and the intensification of violence have been factors that facilitated the disclosure of violence. The following statements confirm this:

"Men should know that they have no right to violence against pregnant women. They have no right to harass a pregnant woman. Pregnancy is sacred, now I came to forensics, I want to make it clear to my husband that he no longer has the right to hit a pregnant woman"(participant 9 – 28 years old- 8 weeks of gestation)

2.3. b. Looking for network support

Domestic violence reduced maternal social network and the result of present study demonstrated the importance of formal and informal support and seek help from these support system in facilitating dealing with domestic violence. Formal support were included health system, psychological counseling, use of welfare services, forensic medical center, social worker, relief committee, the police and Justice. Informal support were included friends and family. Abused mothers formed friendly alliance and asked help from formal and informal support system. The following statements confirm this:

"Abused mothers should be informed about which systems support them. What services can they receive from health centers? Where can they go for psychological counseling? How can they complain about their husbands?" (Participant 27- 37 years old- key informant).

Discussion
This is the first qualitative study in Iran which identified maternal strategies for managing perinatal domestic violence. According to the results, maternal strategies used for managing perinatal domestic violence included adopting escape strategies and applying situation improvement strategies. In the shadow of maternal commitment to preserve marriage and child health, mostly abused mothers in the early stage of confronting with violence used emotion oriented strategies such as adopting escape strategies for managing violence, gradually the recurrence and intensifying of violence caused applying situation improvement strategies. These results are consistent with Lazarus and Folkman conceptualization in which adopting escape strategies can be considered as emotion focused coping and applying situation improvement strategies can be considered as problem focus coping (46).

Despite the routine screening for domestic violence during prenatal care, the majority of abused Iranian mothers concealed perinatal domestic violence. They hided violence from family, friends, the health care system and the legal system. Several factors were important in concealing violence such as inadequate information on violence, maintaining social reputation, protecting the unborn child, facing with multiple fears, social judgments, lack of family support and poor performance of health care and judicial systems. These result was consistent with Damra JK et al. study (47).

Similar to a study by Kaye et al., (2007), findings from this study showed abused young mothers adopted retaliation and fighting back as an emotion oriented strategy which usually had no effect on reducing violence but sometimes intensfied husband's violence (30). Similarly few abused mothers harmed themselves to cope with the psychological stress and presented additional health concerns which is align with previous study conducted by Bhandari et al. (2011)(19). Similar to a research by Zakar et al. (2012), findings from this study revealed that some abused mothers did not submit demands of their husband, ignored them and used husband abuse behavior such as sexual disobedience to get rid of their psychological distress (48). These strategies also had no effect on reducing violence and sometimes cause more violent behavior of husbands. Domestic violence usually cause maternal social and physical withdrawal to decrease their emotional distress. This result was align with the previous study (30).

Some abused mothers tried to deal with their husband violence using neutral behavior, including the use of placating strategies and diverting attention. Consistent with a study conducted by Bhandari et al. (2013), findings from the present study indicated that abused mothers used placating strategies for minimizing the recurrence of perinatal domestic violence and keeping peace in their house (49).

Some mothers, while believing in the needs to cover up violence with regard to individual decision-making and individual abilities, and in the shadow of high self-esteem and self-confidence and the belief in protecting marital life privacy, use active self-regulation such as self-actualization, comprehensive self-care skills, resilience, and strengthening spirituality. Abused mothers could control their distress by these effective strategies. These results indicate the importance of educating mothers about the cycle of domestic violence, the warning signs to look for in marriage and how to develop safety after termination of a violent marital life (50). Self-care is recognized as mindful activities and taken by women, families and societies to promote health status (51).

Some abused mothers displayed resilience through problem oriented coping and actively responding to their harassment such as promote individual growth, being purposeful, source of internal control, flexibility, help seeking, independence, realistic look and thinking positive were the maternal strategies for dealing with domestic violence. Resilience cause maternal wellbeing after violence. The result were similar to the study conducted by Levesque et al.(2016) that victimized pregnant women may display resilience through adjusting to motherhood by generating a bond with their child and creating their maternal identity, connecting with their community to expand levels of social support and making a future of hope (31).

Consistent with the study conducted by Zakar et al. (2012) (48) participants in the current study used strengthening spirituality such as participating in religious ceremonies, relying on God, appealing to the Imams and submitting to the divine destinies as a form of emotion oriented coping strategy. These strategies made abused mother calm in confrontation with domestic violence.

Some mothers used family protection strategies such as purposeful efforts to correct the husband's behavior, supportive efforts, and maintain maternal commitment, in the shadow of satisfaction with cohabitation and concern for social isolation. maintain maternal commitment and the urge to protect the fetus were the important motivaton for dealing with perinatal violence and stay in marital abusive relationship which were inconsistent with Bhandari et al. (2013) (49). Abused mothers in the face of intensifying violence increased activity in protecting themselves and their children which is similar to the result of previous study conducted by Gillum et al. (2006) (18).

A few abused mothers disclosed perinatal domestic violence. Maternal empowerment and familiarity with individual rights, the ability of the health care system to identify violence, the presence of supportive families and supportive systems and intensity of violence have been factors that facilitated the disclosure of violence.

Pregnant and postpartum women used safety planning, resisting, placating, and formal and informal support networks to deal with abuse in their lives. These result were align with Bhandari et al. (2013) study (49).

Results of the present study demonstrated that social support was associated with reduced risk of perinatal domestic violence since this kind of formal support could provide the opportunity for abused mothers to discuss about their vulnerable experiences and receive support in the context of perinatal domestic violence. These result were consistent with the previous studies (20-22).

Findings of the present study indicated that family support could help abused mothers to reduce violence and promoting maternal and fetal health. Similarly family support could help mothers decide to leave the the abused marital relationship which is consistent with previous studies (25, 52).

Women who received psychosocial counselling showed a reduction in the frequency and severity of domestic violence, and this included both physical and emotional abuse. Psychology counseling could be an effective approach to reduce the recurrence of violence in pregnant women exposed to domestic violence. The basics of counseling was empowerment and increasing self-condense. Through this way abused mothers found that they are able to find appropriate solutions to solve domestic violence through their empowerment and positive negotiations with their husbands. The result was similar to the
previous study by Din Mohammad (53, 54). The result of the present study recommended that life skills training classes should be held for abused pregnant women in health centers to reduce the prevalence of prenatal domestic violence which was similar to the study conducted by Taghizadeh et al (55).

In line with the study conducted by Zakar et al. (2012) (48), Bhandari et al. (2013) (49) and Kaye et al. (2007) (30) some abused mothers used problem solving strategies such as gaining formal and informal network support and asked help from these support system which could facilitate dealing with violence.

The results of this study increase understanding of Iranian pregnant women's strategies for managing perinatal domestic violence which could enable supportive system to encourage abused mothers to use more effective strategies and seeking help to reduce domestic violence. These include strengthening formal and informal support systems and facilitating access for abused pregnant and postpartum women to formal and informal services, particularly the effective health care system.

According to the different cultural values of Iranian society further research is needed to explore facilitators and barriers of disclosing domestic violence in pregnancy. Similarly further research is also needed to design interventions for women who report domestic violence during and after pregnancy.

**Strength and Limitation**

This is the first study performed in Iran to explore Iranian women's strategies for managing domestic violence in pregnancy. Similarly, Data collection through interviewing with specialists from various disciplines, diversity of participants and multiple perspectives of domestic violence in pregnancy and postpartum were the strengths of this study. Patriarchal cultural context of Iran and the difficulty to obtain responses from the abused mothers considering the taboo of violence were important limitations of this study. Information regarding domestic violence in pregnancy is considered an individual family issue and should not be discussed with strangers even though they are health care providers that may, in turn, lead to under reporting of domestic violence in pregnancy by the participants.

**Practical implications**

Despite the methodological limitations of the study, our findings will be useful to health care providers, program managers, and policy makers in addition to women and human rights activists. They can be used in the development of specialized training and materials for building providers capacities to deal more effectively with cases of domestic violence in pregnancy and postpartum period and it is also fundamental to collaborate with other professionals in order to develop shared health-care pathways.

**Conclusion**

The high prevalence and the negative consequences of domestic violence against pregnant women provide a golden opportunity for performing interventions. Pregnancy and protection of unborn child could affect maternal strategies for dealing with domestic violence. The results of the various strategies that the mother used to reduce perinatal domestic violence vary from reducing domestic violence to not changing the intensity of the violence or intensifying the perinatal domestic violence. It is noteworthy that adopting inappropriate coping strategies against domestic violence could be threatening for fetal and maternal life and should be considered and emphasized in maternal education. Understanding the experience of domestic violence among these women is essential to design evidence based domestic violence prevention strategies and programs.

**Declarations**

**Ethics approval and consent to participate**

The research was approved by the Local Research Ethics Committee of Mashhad University of Medical Sciences (Code of Ethics: 1398.026) and was performed according to the Helsinki Declaration (44, 45). The participants were fully informed about the purpose and nature of the study as well as their voluntary participation. They were reassured that their right to withdraw from the study without any prejudice, also the privacy and the confidentiality of all their data would be maintained. Written informed consent was obtained from all the participants. If any of the questions caused distress for the participants, the interview was stopped and after a while, and by the participant's permission, it was continued. After the completion of interview the researcher was assured that the participants are not psychologically distressed due to the interview and that there is no need of immediate emotional support. At the end of the interviews, necessary information about the existing services for abused women was given to the participants and they were referred to receive services, if necessary.

**Consent for publication**

Not applicable.

**Availability of data and materials**

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable requests.

**Competing interests**

The authors declare that no potential conflict of interest with respect to the research, authorship, and publication of this article exists.

**Funding**
This study funded by the Vice chancellor for Research, Mashhad University of Medical Sciences (Grant No. 980282), Mashhad, Iran.

**Authors' contributions**

MAB, RB, KHMN, RLR and MMB designed the study. MAB was involved in data collection. MAB and RB finalized verbatim for the results. MAB, RB, KHMN and RLR contributed in data analysis and interpretation. MAB wrote the draft of manuscript while RB, KHMN, RLR did an extensive review of the manuscript. All authors reviewed and approved the final version of the manuscript.

**Acknowledgment**

This study is part of the first author’s (MAB) PhD thesis in Reproductive Health and has been approved and funded by the Research Vice Chancellor of Mashhad University of Medical Sciences, Mashhad, Iran. The authors express their gratitude and appreciation to the participants who cordially shared their experiences with us.
