THE PLANCHEREL FORMULA FOR COMPLEX SEMISIMPLE QUANTUM GROUPS

CHRISTIAN VOIGT AND ROBERT YUNCKEN

Abstract. We calculate the Plancherel formula for complex semisimple quantum groups, that is, Drinfeld doubles of \(q\)-deformations of compact semisimple Lie groups. As a consequence we obtain a concrete description of their associated reduced group \(C^*\)-algebras. The main ingredients in our proof are the Bernstein-Gelfand-Gelfand complex and the Hopf trace formula.

1. Introduction

Complex semisimple quantum groups are locally compact quantum groups which were constructed and first studied by Podleś and Woronowicz [15]. They are defined as Drinfeld doubles of \(q\)-deformations of compact semisimple Lie groups, and can be viewed as deformations of the corresponding complex Lie groups in a natural way. Motivated by physical considerations, Podleś and Woronowicz focussed mainly on the case of the quantum Lorentz group, that is, the Drinfeld double of \(SU_q(2)\). It became clear later that the theory of more general complex semisimple quantum groups is linked with a range of seemingly unrelated problems in noncommutative geometry, operator \(K\)-theory, and the theory of \(C^*\)-tensor categories and subfactors, see for instance [1], [14], [19].

In the present paper we study the reduced unitary dual of complex semisimple quantum groups, and our main result is an explicit computation of the Plancherel formula. This generalizes work of Buffenoir and Roche [4] on the quantum Lorentz group. The formula we obtain can be interpreted as a deformation of the Plancherel formula for the corresponding classical groups, but our method of proof is completely different.

We note that the abstract Plancherel theorem for locally compact quantum groups was established by Desmedt [6], in analogy to the classical theory. In the case of complex semisimple quantum groups the Plancherel theorem involves so-called Duflo-Moore operators because the dual Haar weights fail to be traces. This is analogous to the situation for non-unimodular locally compact groups treated by Duflo and Moore in [8]. A classical locally compact group is unimodular if and only if the Haar weight on its group \(C^*\)-algebra is tracial. In the quantum setting, traciality of the dual Haar weights implies unimodularity, but the converse does not hold in general. This is a well-known phenomenon which already shows up in the theory of compact quantum groups.

Given a locally compact group or quantum group, a key problem is to calculate the Plancherel formula, that is, to determine explicitly the Plancherel measure and Duflo-Moore operators in terms of a given parametrization of the unitary dual. Before describing our proof strategy in the case of complex quantum groups, let us

briefly recall the approach to compute the Plancherel formula for classical complex semisimple Lie groups due to Harish-Chandra [9], see also section 6.1 in [17]. Firstly, the characters of principal series representations are shown to be related to orbital integrals using Fourier transform. In a second step, orbital integrals on the group are transported to the Lie algebra. The final ingredient in the argument is the limit formula for orbital integrals on the Lie algebra, which in combination with the Weyl integration formula completes the proof.

Trying to adapt this strategy to the quantum case seems difficult for various reasons. In fact, it is not even clear how to define a suitable notion of orbital integrals in this setting, and there is no good analogue of the Lie algebra. We proceed by explicitly writing down candidates for the Plancherel measure and Duflo-Moore operators instead, generalizing the ones in [4]. In order to verify that our choices are correct, we determine the characters of principal series representations and define a certain linear functional on the algebra of functions on the quantum group, which we call Plancherel functional. According to the Plancherel inversion formula it then suffices to show that the Plancherel functional agrees with the counit. For this, in turn, we use the BGG complex for quantized universal enveloping algebras studied by Heckenberger and Kolb [10], or more precisely, the complex of Harish-Chandra modules obtained from it via the category equivalence between category and the category of Harish-Chandra modules, see [11], [18]. The key fact that allows us to compute the Plancherel functional is that its values can be identified with Lefschetz numbers of certain endomorphisms of the BGG-complex. Since the BGG-complex has almost trivial homology, an application of the Hopf trace formula completes the proof.

Our result shows in particular that the Plancherel measure of complex semisimple quantum groups is supported on the space of unitary principal series representations, in analogy with the classical situation. This allows us to identify the reduced group $C^*$-algebras of these quantum groups explicitly with certain continuous bundles of algebras of compact operators. As a consequence, one obtains a very transparent illustration of the deformation aspect in the operator algebraic approach to complex semisimple quantum groups, a feature which is not at all visible from the Drinfeld double construction.

Let us now explain how the paper is organized. In section 2 we collect some preliminaries on quantum groups and fix our notation. Section 3 covers more specific background on complex semisimple quantum groups and their representations. We introduce our candidate Duflo-Moore operators for these quantum groups and compute the corresponding twisted characters of unitary principal series representations. In section 4 we recall the abstract Plancherel Theorem for locally compact quantum groups due to Desmedt. Section 5 contains our main result, that is, the Plancherel formula for complex semisimple quantum groups. As already indicated above, the proof involves the BGG-complex, and we review the necessary background material along the way. In section 6 we make some further comments and discuss a slightly different, more direct proof of the Plancherel formula in the simplest special case of the quantum Lorentz group. This argument is considerably shorter than the original proof by Buffenoir and Roche. Finally, in section 7 we apply the Plancherel formula to obtain an explicit description of the reduced group $C^*$-algebras of arbitrary complex semisimple quantum groups.

Let us conclude with some remarks on notation. The algebra of adjointable operators on a Hilbert space or Hilbert module $E$ is denoted by $\mathbb{L}(E)$, and we write $K(E)$ for the algebra of compact operators. Depending on the context, the symbol $\otimes$ denotes the algebraic tensor product over the complex numbers, the tensor product of Hilbert spaces, or the minimal tensor product of $C^*$-algebras.
2. Preliminaries

In this section we review some background material on quantum groups and fix our notation. For more details we refer to [5], [12], [13], [18].

Throughout we assume that our definition parameter $q$ is a strictly positive real number and $q \neq 1$. We write

$$[z]_q = \frac{q^z - q^{-z}}{q - q^{-1}}$$

for the $q$-number associated with $z \in \mathbb{C}$ and use standard definitions and notation from $q$-calculus.

Let $G$ be a simply connected complex semisimple Lie group with Lie algebra $\mathfrak{g}$, and let $\mathfrak{t} \subset \mathfrak{g}$ be the Lie algebra of a maximal compact subgroup $K \subset G$. We fix a Cartan subalgebra $\mathfrak{h} \subset \mathfrak{g}$ and a maximal torus $T$ of $K$ with Lie algebra $\mathfrak{t}$ such that $\mathfrak{t} \subset \mathfrak{h}$. Let us denote by $\Sigma = \{\alpha_1, \ldots, \alpha_N\}$ a set of simple roots for $\mathfrak{g}$, and let $(\cdot, \cdot)$ be the bilinear form on $\mathfrak{h}^*$ obtained by rescaling the Killing form such that the shortest root $\alpha$ of $\mathfrak{g}$ satisfies $(\alpha, \alpha) = 2$. The simple coroots are given by $\alpha_i^\vee = d_i^{-1} \alpha_i$ where $d_i = (\alpha_i, \alpha_i)/2$, and the entries of the Cartan matrix of $\mathfrak{g}$ are $a_{ij} = (\alpha_i^\vee, \alpha_j)$. We write $\varepsilon_1, \ldots, \varepsilon_N$ for the fundamental weights, defined by stipulating $(\varepsilon_i, \alpha_j) = \delta_{ij}$. Moreover we denote by $\mathfrak{Q} \subset \mathfrak{P} \subset \mathfrak{h}^*$ the root and weight lattices of $\mathfrak{g}$, respectively. The set $\mathfrak{P}^+ \subset \mathfrak{P}$ of dominant integral weights consists of all non-negative integer combinations of the fundamental weights.

**Definition 2.1.** The quantized universal enveloping algebra $U_q(\mathfrak{g})$ is the complex algebra with generators $K_\lambda$ for $\lambda \in \mathfrak{P}$, and $E_i, F_i$ for $i = 1, \ldots, N$, and the defining relations

$$K_0 = 1$$
$$K_\lambda K_\mu = K_{\lambda + \mu}$$
$$K_\lambda E_j K_\lambda^{-1} = q^{(\lambda, \alpha_j)} E_j$$
$$K_\lambda F_j K_\lambda^{-1} = q^{-(\lambda, \alpha_j)} F_j$$
$$[E_i, F_j] = \delta_{ij} \frac{K_i - K_i^{-1}}{q_i - q_i^{-1}}$$

for all $\lambda, \mu \in \mathfrak{P}$ and all $i, j$, together with the quantum Serre relations

$$\sum_{k=0}^{1-a_{ij}} (-1)^k \left[ \frac{1 - a_{ij}}{k} \right]_{q_i} E_i^k E_j E_i^{1-a_{ij}-k} = 0$$
$$\sum_{k=0}^{1-a_{ij}} (-1)^k \left[ \frac{1 - a_{ij}}{k} \right]_{q_i} F_i^k F_j F_i^{1-a_{ij}-k} = 0.$$

In the above formulas we abbreviate $K_i = K_{\alpha_i}$ for all simple roots, and we use the notation $q_i = q^{a_{ij}}$.

We consider the Hopf algebra structure on $U_q(\mathfrak{g})$ determined by the comultiplication $\hat{\Delta} : U_q(\mathfrak{g}) \to U_q(\mathfrak{g}) \otimes U_q(\mathfrak{g})$ given by

$$\hat{\Delta}(K_\lambda) = K_\lambda \otimes K_\lambda$$
$$\hat{\Delta}(E_i) = E_i \otimes K_i + 1 \otimes E_i$$
$$\hat{\Delta}(F_i) = F_i \otimes 1 + K_i^{-1} \otimes F_i,$$

coaction $\hat{\epsilon} : U_q(\mathfrak{g}) \to \mathbb{C}$ given by

$$\hat{\epsilon}(K_\lambda) = 1, \quad \hat{\epsilon}(E_i) = 0, \quad \hat{\epsilon}(F_i) = 0.$$
and antipode \( \hat{S} : U_q(\mathfrak{g}) \to U_q(\mathfrak{g}) \) given by
\[
\hat{S}(K_\lambda) = K_{-\lambda}, \quad \hat{S}(E_i) = -E_i K_j^{-1}, \quad \hat{S}(F_j) = -K_j F_j
\]
on generators. We will use the Sweedler notation \( \hat{\Delta}(X) = X_{(1)} \otimes X_{(2)} \) for the comultiplication of \( U_q(\mathfrak{g}) \).

We denote by \( U_q(\mathfrak{h}) \) the subalgebra of \( U_q(\mathfrak{g}) \) generated by the elements \( K_\lambda \) for \( \lambda \in \mathbf{P}_\ast \), and let \( \mathfrak{h}^\ast_q \) be the space of all algebra characters \( U_q(\mathfrak{h}) \to \mathbb{C} \). Every such character is of the form \( \chi_\lambda(K_\mu) = q^{\langle \lambda, \mu \rangle} \) for some \( \lambda \in \mathfrak{h}^\ast \), and if we write \( q = e^h \) and \( h = \frac{\hbar}{2\pi} \) we obtain an identification
\[
\mathfrak{h}^\ast_q = \mathfrak{h}^\ast / \hbar^{-1} \mathbf{Q}^\ast
\]
in this way, where \( \mathbf{Q}^\ast \) is the coroot lattice.

Let \( V \) be a left module over \( U_q(\mathfrak{g}) \). For \( \lambda \in \mathfrak{h}^\ast_q \) we define the weight space
\[
V_\lambda = \{ v \in V \mid K_\mu \cdot v = q^{\langle \mu, \lambda \rangle} v \text{ for all } \mu \in \mathbf{P} \}.
\]
We say that \( \lambda \) is a weight of \( V \) if \( V_\lambda \) is nonzero. A vector \( v \in V \) is said to have weight \( \lambda \) iff \( v \in V_\lambda \). A highest weight vector is a weight vector \( v \) such that \( E_i \cdot v = 0 \) for \( 1, \ldots, N \). A module \( V \) over \( U_q(\mathfrak{g}) \) is called a weight module if it is the direct sum of its weight spaces \( V_\lambda \) for \( \lambda \in \mathfrak{h}^\ast_q \).

The Verma module \( M(\lambda) \) is the universal weight module over \( U_q(\mathfrak{g}) \) generated by a highest weight vector \( v_\lambda \) of weight \( \lambda \in \mathfrak{h}^\ast_q \). As in the classical case it admits a unique irreducible quotient \( V(\lambda) \).

We say that a weight module \( V \) is integrable if the operators \( E_i, F_j \) are locally nilpotent on \( V \) for all \( 1 \leq i, j \leq N \) and the weights of \( V \) are all contained in \( \mathbf{P} \subset \mathfrak{h}_q^\ast \). Every finite dimensional weight module is completely reducible, and the irreducible integrable finite dimensional weight modules of \( U_q(\mathfrak{g}) \) are parametrized by their highest weights in \( \mathbf{P}_q^\ast \) as in the classical theory. If \( \mu \in \mathbf{P}_q^\ast \) we will write \( \pi_\mu : U_q(\mathfrak{g}) \to \text{End}(V(\mu)) \) for the corresponding representation. The direct sum of the maps \( \pi_\mu \) induces an embedding \( \pi : U_q(\mathfrak{g}) \to \prod_{\mu \in \mathbf{P}_q^\ast} \text{End}(V(\mu)) \).

The space of all matrix coefficients of finite dimensional integrable weight modules over \( U_q(\mathfrak{g}) \) is denoted by \( \mathcal{O}(G_q) \). It becomes a Hopf algebra with multiplication, comultiplication, counit and antipode in such a way that the canonical evaluation \( U_q(\mathfrak{g}) \times \mathcal{O}(G_q) \to \mathbb{C} \) is a skew-pairing, that is, we have
\[
(\pi_{\mu_1} \cdot \pi_{\mu_2}, f) = (\pi_{\mu_1}, f \cdot \pi_{\mu_2}), \quad (\pi_{\mu_1} \cdot \pi_{\mu_2}, f) = (\pi_{\mu_1}, f) (\pi_{\mu_2}, g)
\]
and
\[
(\hat{\Delta}(X), f) = (X, S^{-1}(f)), \quad (\hat{S}^{-1}(X), f) = (X, S(f))
\]
for \( X, Y \in U_q(\mathfrak{g}) \) and \( f, g \in \mathcal{O}(G_q) \). Here we use the Sweedler notation \( \Delta(f) = f_{(1)} \otimes f_{(2)} \) for the coproduct of \( f \in \mathcal{O}(G_q) \), and write \( S, \epsilon \) for the antipode and counit of \( \mathcal{O}(G_q) \).

Let us next discuss \(*\)-structures. The quantized universal enveloping algebra \( U_q(\mathfrak{g}) \) is a Hopf \(*\)-algebra with \(*\)-structure given by
\[
E_i^* = K_i F_i, \quad F_i^* = E_i K_i^{-1}, \quad K_\lambda^* = K_\lambda. \tag{1}
\]

With the above \(*\)-structure, \( U_q(\mathfrak{g}) \) should be viewed as the quantized universal enveloping algebra of the complexification of \( \mathfrak{t} \), and as such we shall write \( U_q^\mathbb{C}(\mathfrak{t}) \) for \( U_q(\mathfrak{g}) \) when we consider it as a Hopf \(*\)-algebra. The representations \( V(\mu) \) for \( \mu \in \mathbf{P} \) are \(*\)-representations with respect to a uniquely determined inner product on \( V(\mu) \) for which the highest weight vector \( v_\mu \) has norm 1.

Dually, we obtain a Hopf \(*\)-algebra structure on \( \mathcal{O}(G_q) \) by stipulating
\[
(X, f^*) = \overline{(S^{-1}(X))^*}, f)
\]
for \( f \in \mathcal{O}(G_q) \) and \( X \in U_q^R(\mathfrak{g}) \). We will write \( \mathcal{C}^\infty(K_q) \) for \( \mathcal{O}(G_q) \) when we consider it as a Hopf \( * \)-algebra in this way. The canonical bilinear pairing between \( U_q(\mathfrak{g}) \) and \( \mathcal{O}(G_q) \) then defines a skew-pairing of the Hopf \( * \)-algebras \( U_q^R(\mathfrak{g}) \) and \( \mathcal{C}^\infty(K_q) \). The algebra \( \mathcal{C}^\infty(K_q) \) can be viewed as a deformation of the Hopf \( * \)-algebra of representative functions on the compact group \( K \). We will also write \( U_q^R(\mathfrak{h}) \) for the Hopf \( * \)-subalgebra of \( U_q^R(\mathfrak{g}) \) with underlying algebra \( U_q(\mathfrak{h}) \).

For each \( \mu \in \mathbb{P}^+ \) we fix an orthonormal basis \( e_1^\mu, \ldots, e_n^\mu \) of \( V(\mu) \) consisting of weight vectors, where \( n = \dim(V(\mu)) \). Then the formulas

\[
(X, u^\mu_{ij}) = \langle e_i^\mu, \pi_\mu(X)(e_j^\mu) \rangle = \langle e_i^\mu, X \cdot e_j^\mu \rangle
\]
define the corresponding matrix coefficients \( u^\mu_{ij} \in \mathcal{C}^\infty(K_q) \), and we note that \( (u^\mu_{ij})^* = S(u^\mu_{ji}) \). If \( \rho \in \mathbb{P} \) denotes the half-sum of all positive roots then the quantum dimension of \( V(\mu) \) is defined by

\[
\dim_q(V(\mu)) = \text{tr}_V(\pi_\mu(K_{2\rho})) = \sum_{j=1}^n (K_{-2\rho}, u^\mu_{ij}),
\]
where \( \text{tr}_V(\mu) \in \mathcal{C}^\infty(K_q) \) denotes the natural trace on \( V(\mu) \). If we write \( \phi \) for the Haar state of \( \mathcal{C}^\infty(K_q) \), then the Schur orthogonality relations are

\[
\phi(u^\mu_{ij} S(u^\mu_{ik})) = \delta_{\beta, \beta} \frac{(K_{-2\rho}, u^\beta_{ij})}{\dim_q(V(\beta))}, \quad \phi(S(u^\mu_{ji}) u^\mu_{ik}) = \delta_{\beta, \beta} \frac{(K_{2\rho}, u^\beta_{ji})}{\dim_q(V(\beta))}
\]
compare for instance chapter 11 in [12]. These relations imply the modular property

\[
\phi(fg) = (K_{2\rho}, g(1)g(3))\phi(g(2)f)
\]
for all \( f, g \in \mathcal{C}^\infty(K_q) \).

The Hopf \( * \)-algebra \( \mathcal{C}^\infty(K_q) \) is an algebraic quantum group in the sense of Van Daele [16], that is, a multiplier Hopf \( * \)-algebra with nonzero positive left invariant Haar functional. We write \( \mathcal{D}(K_q) \) for the dual algebraic quantum group. Explicitly, the dual is given by the algebraic direct sum

\[
\mathcal{D}(K_q) = \operatorname{alg} \bigoplus_{\mu \in \mathbb{P}^+} \mathbb{K}(V(\mu))
\]
with the \( * \)-structure arising from the \( C^* \)-algebras \( \mathbb{K}(V(\mu)) = \operatorname{End}(V(\mu)) \). We denote by \( p_\eta \) the central projection in \( \mathcal{D}(K_q) \) corresponding to the matrix block \( \mathbb{K}(V(\eta)) \) for \( \eta \in \mathbb{P}^+ \).

There exists a unique bilinear pairing \( \mathcal{D}(K_q) \times \mathcal{C}^\infty(K_q) \to \mathbb{C} \) such that

\[
(xy, f) = (x, f_{(1)})(y, f_{(2)}), \quad (x, fg) = (x_{(2)}, f)(x_{(1)}, g)
\]
and

\[
(\hat{S}(x), f) = (x, S^{-1}(f)), \quad (\hat{S}^{-1}(x), f) = (x, S(f))
\]
for \( f, g \in \mathcal{C}^\infty(K_q) \) and \( x, y \in \mathcal{D}(K_q) \). The compatibility with the \( * \)-structures is given by

\[
(x, f^*) = (\hat{S}^{-1}(x)^*, f), \quad (x^*, f) = (x, S(f)^*).
\]
Positive left and right Haar functionals for \( \mathcal{D}(K_q) \) are given by

\[
\phi(x) = \sum_{\mu \in \mathbb{P}^+} \dim_q(V(\mu)) \text{tr}(K_{2\rho} p_\mu x), \quad \psi(x) = \sum_{\mu \in \mathbb{P}^+} \dim_q(V(\mu)) \text{tr}(K_{-2\rho} p_\mu x),
\]
respectively.

Let us write

\[
\mathcal{M}(\mathcal{D}(K_q)) = \operatorname{alg} \prod_{\mu \in \mathbb{P}^+} \mathbb{K}(V(\mu))
\]
for the algebraic multiplier algebra of \( \mathfrak{D}(K_q) \). The pairing between \( \mathfrak{D}(K_q) \) and \( \mathcal{C}^\infty(K_q) \) extends uniquely to a bilinear pairing between \( \mathcal{M}(\mathfrak{D}(K_q)) \) and \( \mathcal{C}^\infty(K_q) \). If we consider the canonical embedding \( U_q^\mathbb{R}(t) \subset \mathcal{M}(\mathfrak{D}(K_q)) \), then this is compatible with our original pairing between \( U_q^\mathbb{R}(t) \) and \( \mathcal{C}^\infty(K_q) \).

By Pontrjagin duality, we can also view \( \mathfrak{D}(K_q) \) as function algebra of the dual algebraic quantum group \( \hat{K}_q \), and \( \mathcal{C}^\infty(K_q) \) as its dual. However, when one flips the roles of the two algebras one has to be slightly careful. In particular, the natural pairing \( \mathcal{C}^\infty(K_q) \times \mathfrak{D}(K_q) \to \mathbb{C} \) is defined by

\[
(f, x) = (\hat{S}(x), f) = (x, S^{-1}(f))
\]

for \( f \in \mathcal{C}^\infty(K_q) \) and \( x \in \mathfrak{D}(K_q) \). The antipode is needed in order to obtain the skew-pairing property and the correct behaviour with respect to the \(*\)-structures on both sides. We emphasize that, with these conventions, we have \( (f, x) \neq (x, f) \) in general.

Given the basis of matrix coefficients \( u_{ij}^\mu \) in \( \mathcal{C}^\infty(K_q) \) as above we obtain a dual linear basis of matrix units \( \omega_{ij}^\nu \) of \( \mathfrak{D}(K_q) \) satisfying

\[
(\omega_{ij}^\nu, u_{kl}^\mu) = \delta_{\mu\nu}\delta_{ik}\delta_{jl}.
\]

The fundamental multiplicative unitary of the quantum group \( K_q \) is the algebraic multiplier of \( \mathcal{C}^\infty(K_q) \otimes \mathfrak{D}(K_q) \) given by

\[
W = \sum_{\mu \in \mathbb{P}^+} \sum_{i,j=1}^{\dim(V(\mu))} u_{ij}^\mu \otimes \omega_{ij}^\mu,
\]

and we have the formula

\[
W^{-1} = (S \otimes \text{id})(W) = (\text{id} \otimes \hat{S}^{-1})(W)
\]

for its inverse.

With these preparations in place, let us now discuss the main object of study in this paper, namely the Drinfeld double \( G_q = K_q \rtimes \hat{K}_q \). By definition, this is the algebraic quantum group given by the \(*\)-algebra

\[
\mathcal{C}_c(G_q) = \mathcal{C}^\infty(K_q) \otimes \mathfrak{D}(K_q),
\]

with comultiplication

\[
\Delta_{G_q} = (\text{id} \otimes \sigma \otimes \text{id})(\text{id} \otimes \text{ad}(W) \otimes \text{id})(\Delta \otimes \hat{\Delta}),
\]

comunit

\[
\epsilon_{G_q} = \epsilon \otimes \hat{\epsilon},
\]

and antipode

\[
S_{G_q}(f \otimes x) = W^{-1}(S(f) \otimes \hat{S}(x))W = (S \otimes \hat{S})(W(f \otimes x)W^{-1}).
\]

Here \( W \in \mathcal{M}(\mathcal{C}^\infty(K_q) \otimes \mathfrak{D}(K_q)) \) denotes the multiplicative unitary from above. A positive left and right invariant Haar functional for \( \mathcal{C}_c^\infty(G_q) \) is given by

\[
\phi_{G_q}(f \otimes x) = \phi(f)\hat{\psi}(x),
\]

compare [15].

Dually, we obtain the convolution algebra \( \mathfrak{D}(G_q) = \mathfrak{D}(K_q) \rtimes \mathcal{C}^\infty(K_q) \), which has \( \mathfrak{D}(K_q) \otimes \mathcal{C}^\infty(K_q) \) as its underlying vector space, equipped with the tensor product comultiplication and the multiplication

\[
(x \triangleright f)(y \triangleright g) = x(y_{(1)}, f_{(1)})y_{(2)} \triangleright f_{(2)}(\hat{S}(y_{(3)}), f_{(3)})g.
\]
The $*$-structure of $\mathcal{D}(G_q)$ is defined in such a way that the natural inclusion homomorphisms $\mathcal{D}(K_q) \to \mathcal{D}(G_q)$ and $\mathcal{C}^\infty(K_q) \to \mathcal{M}(\mathcal{D}(G_q))$ are $*$-homomorphisms. We shall work with the skew-pairing
\[(y \triangleright g, f \otimes x) = (y, f)(g, x)\]
between $\mathcal{D}(G_q)$ and $\mathcal{C}^\infty(G_q)$, and we remark that this is compatible with the $*$-structures.

Both $*$-algebras $\mathcal{C}^\infty(G_q)$ and $\mathcal{D}(G_q)$ admit universal $C^*$-completions, which will be denoted by $C_q(G_q)$ and $C^*_q(G_q)$, respectively. By definition, a unitary representation of $G_q$ on a Hilbert space $\mathcal{H}$ is a nondegenerate $*$-homomorphism $\pi : C^*_q(G_q) \to \mathcal{L}(\mathcal{H})$. A basic example is the left regular representation of $G_q$, which is obtained from the canonical $*$-homomorphism $C^*_q(G) \to \mathcal{L}(L^2(G_q))$. Here $L^2(G_q)$ is the GNS-construction of the left Haar functional of $G_q$. The image of $C^*_q(G)$ under the regular representation is the reduced group $C^*$-algebra $C^*_r(G_q) \subset \mathcal{L}(L^2(G_q))$.

Let us finally recall that the group algebra $\mathcal{D}(G_q)$ can be identified with the vector space $\mathcal{C}^\infty(G_q)$ equipped with the convolution product
\[f * g = \phi_{G_q}(S_{G_q}^{-1}(g_1)f)g(2) = \phi_{G_q}(S_{G_q}^{-1}(g)f_2)f(1)\]
by Fourier transform. More precisely, the linear map $\mathcal{F} : \mathcal{C}^\infty(G_q) \to \mathcal{D}(G_q)$ determined by
\[(\mathcal{F}(f), h) = \phi_{G_q}(hf)\]
is a linear isomorphism which identifies $\mathcal{C}^\infty(G_q)$, equipped with the convolution product, with $\mathcal{D}(G_q)$ as algebras. It becomes an isomorphism of $*$-algebras if we consider the $*$-structure defined by $f^* = \mathcal{F}^{-1}(\mathcal{F}(f)^*)$ for $f \in \mathcal{C}^\infty(G_q)$, not to be confused with the $*$-structure underlying $\mathcal{C}^\infty(G_q)$. We will mainly work with this description of the group algebra $\mathcal{D}(G_q)$ in our calculations below.

3. Representation theory of complex quantum groups

In this section we review some central facts regarding the representation theory of complex quantum groups. For the proofs of these results as well as further background we refer to [18]. Throughout we assume that $q = e^h$ is a strictly positive real number and $q \neq 1$.

Let $\mu \in \mathfrak{P}$. Then we define the space of sections $\Gamma(\mathcal{E}_\mu) \subset \mathcal{C}^\infty(K_q)$ of the induced vector bundle $\mathcal{E}_\mu$ corresponding to $\mu$ to be the subspace of $\mathcal{C}^\infty(K_q)$ of weight $\mu$ with respect to the $U^\mathbb{R}_q(\mathfrak{t})$-module structure
\[X \rightarrow \xi = \xi_{(1)}(X, \xi_{(2)}).\]
Equivalently, we have
\[\Gamma(\mathcal{E}_\mu) = \{\xi \in \mathcal{C}^\infty(K_q) \mid (\text{id} \otimes \pi_T)\Delta(\xi) = \xi \otimes e^h\},\]
where $\pi_T : \mathcal{C}^\infty(K_q) \to \mathcal{C}^\infty(T)$ is the canonical projection homomorphism and $e^h \in \mathcal{C}^\infty(T)$ is the generator corresponding to the weight $\mu$. We note that $\mathcal{C}^\infty(T)$ is the quotient of $\mathcal{C}^\infty(K_q)$ corresponding to the Hopf $*$-subalgebra $U^\mathbb{R}_q(\mathfrak{t}) \subset U^\mathbb{R}_q(\mathfrak{g})$.

For $\lambda \in \mathfrak{h}_q^*$ we define the twisted left adjoint action of $\mathcal{C}^\infty(K_q)$ on $\Gamma(\mathcal{E}_\mu)$ by
\[f \cdot \xi = f_{(1)}\xi S(f_{(3)})(K_{2\rho + \lambda}, f_{(2)}).\]
Together with the left coaction $\Gamma(\mathcal{E}_\mu) \to \mathcal{C}^\infty(K_q) \otimes \Gamma(\mathcal{E}_\mu)$ given by comultiplication this turns $\Gamma(\mathcal{E}_\mu)$ into a Yetter-Drinfeld module. We will frequently switch from the left coaction on $\Gamma(\mathcal{E}_\mu)$ to the left $\mathcal{D}(K_q)$-module structure given by
\[x \cdot \xi = (\hat{S}(x), \xi_{(1)}(x))\xi_{(2)}\]
for \(x \in \mathcal{D}(K)\). Combining this with the action of \(\mathcal{E}^{\infty}(K)\) from above makes \(\Gamma(\mathcal{E}_\mu)\) into a \(\mathcal{D}(G_q)\)-module, which we denote by \(\Gamma(\mathcal{E}_\mu,\lambda)\) and refer to as the principal series module with parameter \((\mu, \lambda) \in \mathbf{P} \times \mathfrak{h}^*_q\).

Let us write \(t_q^\nu = t^\nu / h^{-1}Q^\nu \subset \mathfrak{h}^*_q\), where, by slight abuse of notation, we view the dual space \(t^\nu = \text{Hom}_\mathbb{R}(t, \mathbb{R})\) as real vector subspace of \(\mathfrak{h}^* = \text{Hom}_\mathbb{C}(\mathfrak{h}, \mathbb{C}) \cong \text{Hom}_\mathbb{R}(t, \mathbb{C})\). It will also be convenient to consider \(t^\nu = i\mathfrak{a}^*\) and work with \(a_q^* = \mathfrak{a}^*/h^{-1}Q^\nu\), so that \(i a_q^* \subset \mathfrak{h}^*_q\) can be identified with \(t_q^\nu\).

For \(\lambda \in t_q^\nu\), or equivalently \(\lambda = iv\) for \(v \in a_q^*\), the Yetter-Drinfeld module \(\Gamma(\mathcal{E}_{\mu,\lambda}) \subset \mathcal{E}^{\infty}(K)\) is unitary for the standard scalar product on \(\mathcal{E}^{\infty}(K)\). In particular, we obtain a corresponding nondegenerate \(\ast\)-representation \(\pi_{\mu,iv} : C^*_r(G_q) \to L(\mathcal{H}_{\mu,iv})\), where \(\mathcal{H}_{\mu,iv} \subset L^2(K)\) is the Hilbert space completion of \(\Gamma(\mathcal{E}_{\mu,iv})\).

**Definition 3.1.** The unitary representations of \(G_q\) on \(\mathcal{H}_{\mu,iv}\) for \((\mu, \nu) \in \mathbf{P} \times a_q^*\) as above are called unitary principal series representations.

For proofs of the following results we refer to chapter 5 of [13].

**Theorem 3.2.** For all \((\mu, \nu) \in \mathbf{P} \times a_q^*\) the unitary principal series representation \(\mathcal{H}_{\mu,iv}\) is an irreducible representation of \(G_q\).

The Weyl group \(W\) acts on the parameter space \(\mathbf{P} \times a_q^*\) by

\[ w(\mu, \nu) = (w\mu, w\nu). \]

The following result describes the isomorphisms between unitary principal series representations in the quantum case.

**Theorem 3.3.** Let \((\mu, \nu), (\mu', \nu') \in \mathbf{P} \times a_q^*\). Then \(\mathcal{H}_{\mu,iv}\) and \(\mathcal{H}_{\mu',iv'}\) are equivalent representations of \(G_q\) iff \((\mu, \nu), (\mu', \nu')\) are in the same Weyl group orbit, that is, iff \((\mu', \nu') = (w\mu, w\nu)\) for some \(w \in W\).

In the remainder of this section we shall study the characters of unitary principal series representations. Fix \((\mu, \nu) \in \mathbf{P} \times a_q^*\), and let \(f\) be an element of the convolution algebra \(\mathcal{E}^{\infty}(G)\). We will write \(\pi_{\mu,iv}(f)\) for the corresponding operator on \(\mathcal{H}_{\mu,iv}\), by identifying \(f\) with an element of \(\mathcal{D}(G_q) \subset C^*_r(G_q)\) as explained at the end of section 2. It follows from the structure of induced bundles that \(\pi_{\mu,iv}(f)\) is a finite rank operator. In particular, the operator \(\pi_{\mu,iv}(f)\) is trace-class, and we shall be interested in finding an explicit formula for certain twisted version of its operator trace.

Let us recall that the homogeneous vector bundle \(\mathcal{E}_\mu\) can be described both using sections of an associated vector bundle over \(K_q/T_q\) and as sections of an associated vector bundle over \(G_q/B_q\), where \(B_q\) denotes the quantum analogue of the minimal parabolic subgroup \(B \subset G\). The latter is defined as the relative Drinfeld double \(T \rtimes K_q\), so that \(\mathcal{E}^{\infty}(B_q) = \mathcal{E}^{\infty}(T) \otimes \mathcal{D}(K_q)\), with a suitable twisted comultiplication.

Our definition of \(\Gamma(\mathcal{E}_{\mu,iv}) = \Gamma(\mathcal{E}_\mu)\) above was phrased in the compact picture, namely

\[ \Gamma(\mathcal{E}_{\mu,iv}) = \{ \xi \in \mathcal{E}^{\infty}(K) \mid (\text{id} \otimes \pi_T)\Delta(\xi) = \xi \otimes e^\mu \}. \]

In the noncompact picture, we consider instead elements \(\sigma\) of the algebraic multiplier algebra \(\mathcal{E}^{\infty}(G_q)\) of \(\mathcal{E}^{\infty}(G_q)\) such that

\[ (\text{id} \otimes \pi_{B_q})\Delta_{G_q}(\sigma) = \sigma \otimes (e^\mu \otimes K_{2\rho+iv}). \]

Here \(K_{2\rho+iv}\) is viewed as multiplier of \(\mathcal{D}(K_q)\) inside \(\mathcal{E}^{\infty}(G_q) = \mathcal{M}(\mathcal{E}^{\infty}(G_q))\), and \(\pi_{B_q} : \mathcal{E}^{\infty}(G_q) \to \mathcal{E}^{\infty}(B_q)\) is the canonical projection. If \(\xi \in \Gamma(\mathcal{E}_{\mu,iv})\) then the
corresponding element \( \text{ext}(\xi) \) in the noncompact picture is given by

\[
\text{ext}(\xi) = \xi \otimes K_{2p+iv} \in \mathcal{C}^\infty(G_q).
\]

Conversely, if \( \sigma \in \mathcal{C}^\infty(G_q) \) satisfies the invariance condition in the noncompact picture then

\[
\text{res}(\sigma) = (\text{id} \otimes \hat{e})(\sigma)
\]

is contained in \( \Gamma(\mathcal{E}_{\mu,iv}) \), and the maps \( \text{ext} \) and \( \text{res} \) are inverse to each other \cite{18}.

Recall that we may identify the group algebra \( \mathcal{D}(G_q) \) with \( \mathcal{C}^\infty(G_q) \) using Fourier transform, where the latter is equipped with convolution. With this in mind, the action of \( f \in \mathcal{C}^\infty(G_q) \) on \( \xi \in \Gamma(\mathcal{E}_{\mu,iv}) \) is given by

\[
\pi_{\mu,iv}(f)(\xi) = \phi_{G_q}(S_{G_q}^{-1}(\text{ext}(\xi)))f(\xi)\text{res}(f(\xi)).
\]

In particular, if \( f = a \otimes t \) for \( a \in \mathcal{C}^\infty(K_q) \) and \( t \in \mathcal{D}(K_q) \), then using

\[
S_{G_q}^{-1}(\text{ext}(\xi)) = S_{G_q}^{-1}(\xi \otimes K_{2p+iv}) = W^{-1}(S^{-1}(\xi) \otimes K_{-2p-iv})W
\]

we obtain

\[
\pi_{\mu,iv}(f)(\xi) = \sum_{\nu,\eta \in \mathcal{P}^+ \cap n,r,s} \phi(S(u_{\nu,\eta}^\mu)S^{-1}(\xi)u_{\nu,\eta}^\mu a(2))\hat{\psi}(\omega_{\nu,\eta}^\mu K_{-2p-iv}\omega_{\nu,\eta}^\mu t)\hat{a}(1)
\]

taking into account that the operator \( K_{-2p-iv} \) is diagonal in our chosen basis of the representation \( V(\eta) \). For \( f = u_{\mu,\nu}^\eta \otimes \omega_{kl}^\gamma \), this formula reduces to

\[
\pi_{\mu,iv}(f)(\xi) = \sum_{r,s} \text{dim}_q(V(\gamma))\phi(S(u_{\nu,\eta}^\mu)S^{-1}(\xi)u_{\nu,\eta}^\mu \gamma_{k,mj}^\beta)q^{-(2p,\epsilon_r+\epsilon_s)}\epsilon_r \epsilon_s \omega_{\gamma,km}^\beta.
\]

Here we write \( \epsilon_m = \mu \) for the weight of the basis vector \( e_m^\mu \) in the definition of the matrix coefficient \( u_{\gamma,km}^\beta \), and note that for \( \xi \in \Gamma(\mathcal{E}_{\mu,iv}) \) only terms with \( \epsilon_m = \mu \) give nonzero contributions in the expression on the right hand side by weight considerations.

Let us now introduce certain operators which will turn out to be the Duflo-Moore operators for \( G_q \), compare Theorem \ref{3.4} below.

**Definition 3.4.** For \( (\mu,iv) \in \mathcal{P} \times a_q^* \) we let \( D_{\mu,iv} \) be the unbounded linear operator in \( \mathcal{H}_{\mu,iv} \) given by

\[
D_{\mu,iv}(\xi) = \pi_{\mu,iv}(K_{-2p} \otimes 1)(\xi) = (K_p, \xi(1))\xi(2)
\]

for \( \xi \in \Gamma(\mathcal{E}_{\mu,iv}) \).

Here \( K_{-2p} \otimes 1 \) is viewed as a multiplier of \( \mathcal{D}(G_q) \) in the obvious way, and we use that the representation \( \pi_{\mu,iv} \) extends naturally to a representation of \( \mathcal{M}(\mathcal{D}(G_q)) \) on \( \Gamma(\mathcal{E}_{\mu,iv}) \).

Using the Peter-Weyl decomposition of \( \mathcal{H}_{\mu,iv} \subset L^2(K_q) \), it is straightforward to check that the formula in Definition \ref{3.4} uniquely determines an unbounded strictly positive self-adjoint operator in \( \mathcal{H}_{\mu,iv} \), which will again be denoted by \( D_{\mu,iv} \). We observe that

\[
D_{\mu,iv}(\xi) = \pi_{\mu,iv}(K_{2p} \otimes 1)(\xi) = (K_{-2p}, \xi(1))\xi(2)
\]

for \( \xi \in \Gamma(\mathcal{E}_{\mu,iv}) \).

In the sequel we shall again tacitly identify the group algebra \( \mathcal{D}(G_q) \) with \( \mathcal{C}^\infty_c(G_q) \) equipped with convolution. With this notational convention in mind, we remark that it is straightforward to check that \( \pi_{\mu,iv}(f)D_{\mu,iv}^{-2} \) defines a finite rank operator
on $\mathcal{H}_{\mu,i\nu}$ for all $f \in \mathcal{C}_c^\infty(G_q)$. The operator trace $\text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})$ will be referred to as the twisted character of $\pi_{\mu,i\nu}(f)$.

**Proposition 3.5.** Let $(\mu,i\nu) \in \mathcal{P} \times \mathcal{A}_q^*$ and $f = u_{ij}^\gamma \otimes \omega_{kl} \in \mathcal{C}_c^\infty(G)$. Then the twisted character of $\pi_{\mu,i\nu}(f)$ is given by

$$\text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2}) = q^{-2\rho(\mu)} \dim_q(V(\gamma)) \sum_{\epsilon_m = \mu} \sum_r \phi(u_{ir}^\gamma S^{-1}(u_{mj}^\beta) S^{-1}(u_{rk}^\alpha) u_{im}^\beta) q^{-(iv,\epsilon_r)}.$$  

**Proof.** Using the antipode relation $\hat{S}(X) = K_{2\rho} \hat{S}^{-1}(X) K_{-2\rho}$ we obtain

$$\begin{align*}
(X, S^{-1}(D_{\mu,i\nu}^{-2}(\xi))) &= (\hat{S}(X), (K_{-2\rho}, \xi(1)) \xi(2)) \\
 &= (K_{-2\rho} \hat{S}(X), \xi) \\
 &= (\hat{S}^{-1}(X) K_{-2\rho}, \xi) \\
 &= (q^{-2\rho(\mu)}(X, S(\xi))
\end{align*}$$

for $\xi \in \Gamma(\mathcal{E}_{\mu,i\nu})$ and $X \in U_q^{R}(t)$. Inserting this into the formula for $\pi_{\mu,i\nu}(f)(\xi)$ obtained above and applying the operator trace yields

$$\begin{align*}
\text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2}) &= q^{-2\rho(\mu)} \dim_q(V(\gamma)) \sum_{\epsilon_m = \mu} \sum_r q^{-2\rho(\epsilon_r) + \epsilon_r} \phi(S(u_{ir}^\gamma) S(u_{mj}^\beta) u_{rk}^\alpha u_{im}^\beta) q^{-(iv,\epsilon_r)} \\
 &= q^{-2\rho(\mu)} \dim_q(V(\gamma)) \sum_{\epsilon_m = \mu} \sum_r q^{-2\rho(\epsilon_r) + \epsilon_r} \phi(S^{-1}(u_{mj}^\beta) S^{-1}(u_{rk}^\alpha) u_{im}^\beta u_{ir}^\gamma) q^{-(iv,\epsilon_r)} \\
 &= q^{-2\rho(\mu)} \dim_q(V(\gamma)) \sum_{\epsilon_m = \mu} \sum_r \phi(u_{ir}^\gamma S^{-1}(u_{mj}^\beta) S^{-1}(u_{rk}^\alpha) u_{im}^\beta) q^{-(iv,\epsilon_r)},
\end{align*}$$

using invariance under the antipode and the modular property of the Haar functional.

\[\square\]

4. **The abstract Plancherel Theorem**

In this section we review the abstract Plancherel theorem for locally compact quantum groups due to Desmedt. We refer to [3] for further information.

Let us say that a locally compact quantum group $G$ is second countable if $L^2(G)$ is a separable Hilbert space. By definition, $G$ is type I if the group C*-algebra $C_q^*(G)$ is type I. We write $\text{Irr}(G)$ for the space of equivalence classes of irreducible unitary representations of $G$ with the Fell topology. If $G$ is type I then the space $\text{Irr}(G)$ is a standard Borel space with the Borel structure coming from the Fell topology, see section 4.6 in [7].

Given $\lambda \in \text{Irr}(G)$ let us write $\mathcal{H}_\lambda$ for the underlying Hilbert space of a representative of $\lambda$ and $\pi_\lambda : C_q^*(G) \to \mathcal{L}(\mathcal{H}_\lambda)$ for the corresponding nondegenerate *-homomorphism. We shall also write $HS(\mathcal{H}_\lambda) = \mathcal{H}_\lambda \otimes \mathcal{H}_{\lambda}$ for the space of Hilbert-Schmidt operators on $\mathcal{H}_\lambda$, which we consider as a representation of $G_q$ with the action on the first tensor factor.

The following statement is then a condensed version of Theorem 3.4.1 in [6].

**Theorem 4.1 (Plancherel Theorem).** Let $G$ be a second countable locally compact quantum group of type I. Then there exists a standard measure $m$ on $\text{Irr}(G)$, a measurable field of Hilbert spaces $(\mathcal{H}_\lambda)_{\lambda \in \text{Irr}(G)}$, a measurable field $(D_\lambda)_{\lambda \in \text{Irr}(G)}$ of self-adjoint strictly positive operators for $(\mathcal{H}_\lambda)_{\lambda \in \text{Irr}(G)}$, and an isometric $G$-equivariant isomorphism

$$Q : L^2(G) \to \int_{\text{Irr}(G)} H S(\mathcal{H}_\lambda) d\mu(\lambda),$$

where $\mu$ is the standard measure on $\text{Irr}(G)$.
given by

\[ Q(\hat{A}(x)) = \int_{\text{irr}(G)} \pi_\lambda(x) D_\lambda^{-1} dm(\lambda) \]

on a certain dense subspace of \( L^2(G) \cap L^1(G) \). The Plancherel measure is unique up to equivalence, more precisely, the family of Duflo-Moore operators \((D_\lambda)_{\lambda \in \text{irr}(G)} \) combined with \( m \) are unique up to mutual rescaling.

Here we write \( L^1(G) \) for the predual of the von Neumann algebra \( L^\infty(G) \) associated to \( G \), and \( \Lambda : \hat{\mathcal{N}}_\phi \to L^2(G) \) denotes the GNS-map for dual left Haar weight \( \phi \) of \( G \).

If \( G \) is an algebraic quantum group in the sense of van Daele [10] then the initial domain of definition of the map \( Q \) in Theorem 4.1 contains the space \( \mathcal{E}_c(G) \). For computational purposes the following version of the Plancherel inversion formula will be useful for us.

**Lemma 4.2.** Let \( G \) be a second countable algebraic quantum group of type I. Let \( m \) be a standard measure on \( \text{irr}(G) \) and \((D_\lambda)_{\lambda \in \text{irr}(G)} \) a measurable field of self-adjoint strictly positive operators on a measurable field of Hilbert spaces \((H_\lambda)_{\lambda \in \text{irr}(G)} \).

Then \( m \) is the Plancherel measure with Duflo-Moore operators \((D_\lambda)_{\lambda \in \text{irr}(G)} \) if and only if for all \( f \in \mathcal{E}_c(G) \) the operator \( \pi_\lambda(f) D_\lambda^{-2} \) is trace-class for almost all \( \lambda \in \text{irr}(G) \) and the Plancherel inversion formula

\[ \epsilon(f) = \int_{\text{irr}(G)} \text{tr}(\pi_\lambda(f) D_\lambda^{-2}) dm(\lambda) \]

holds. Here \( \text{tr} \) denotes the operator trace.

**Proof.** We note again that using Fourier transform we tacitly identify the group algebra \( \mathcal{D}(G) \) of \( G \) with \( \mathcal{E}_c(G) \), the latter being equipped with the convolution product \( g \ast h = \phi(S^{-1}(h_{(1)}))g h_{(2)} \) and the \( * \)-structure inherited from \( \mathcal{D}(G) \).

Assume first that \( m \) is the Plancherel measure with corresponding Duflo-Moore operators \((D_\lambda)_{\lambda \in \text{irr}(G)} \). If \( g, h \in \mathcal{E}_c(G) \) then by Theorem 4.1 we have

\[ \langle \Lambda(g), \Lambda(h) \rangle = \int_{\text{irr}(G)} \text{tr}(D_\lambda^{-1} \pi_\lambda(g) \ast \pi_\lambda(h) D_\lambda^{-1}) dm(\lambda) = \int_{\text{irr}(G)} \text{tr}(\pi_\lambda(g \ast h) D_\lambda^{-2}) dm(\lambda). \]

Moreover

\[ \epsilon(g \ast h) = \hat{\phi}(\mathcal{F}(g \ast h)) = \hat{\phi}(\mathcal{F}(g) \ast \mathcal{F}(h)) = \phi(g \ast h) = \langle \Lambda(g), \Lambda(h) \rangle. \]

by properties of the Fourier transform \( \mathcal{F} \), using that \( \hat{\phi}(\mathcal{F}(f)) = \epsilon(f) \) for any \( f \in \mathcal{E}_c(G) \), and keeping in mind the different \( * \)-structures associated with convolution and multiplication in \( \mathcal{E}_c(G) \). In other words, both sides of the Plancherel inversion formula agree on \( f = g \ast h \). Since elements of this form span \( \mathcal{E}_c(G) \) linearly we see that the Plancherel inversion formula holds for all \( f \in \mathcal{E}_c(G) \).

Conversely, if the Plancherel inversion formula holds for all \( f \in \mathcal{E}_c(G) \), then reversing the previous argument shows that the formula for the map \( Q \) in Theorem 4.1 defines an isometric linear map on the dense subspace \( \mathcal{E}_c(G) \subset L^2(G) \). From this it follows that the measure \( m \) and the operators \((D_\lambda)_{\lambda \in \text{irr}(G)} \) satisfy the properties listed in Theorem 4.1 and therefore are the Plancherel measure with corresponding Duflo-Moore operators.

Theorem 4.1 provides a complete description of the regular representation of the quantum group \( G \) at an abstract level. A key problem in harmonic analysis is to compute the Plancherel measure and corresponding Duflo-Moore operators concretely, given a parametrization of the space of irreducible representations.
5. The Plancherel formula for complex quantum groups

In this section we give an explicit description of the Plancherel formula for complex semisimple quantum groups. We remark that these quantum groups are indeed type I, see Chapter 5 in [13], so that Theorem 4.1 applies. As in the classical case, our result shows in particular that the support of the Plancherel measure for a complex semisimple quantum group is the space of unitary principal series representations.

**Theorem 5.1.** Let \( G_q \) be a complex semisimple quantum group. Moreover let \( H = (H_{\mu,i\nu})_{\mu,i\nu} \) be the Hilbert space bundle over \( P \times a_q^* \) of unitary principal series representations of \( G_q \). Then there is a \( G \)-equivariant unitary isomorphism

\[
Q : L^2(G_q) \to \bigoplus_{\mu \in P} \int_{\nu \in a_q^*} HS(H_{\mu,i\nu})dm_\mu(\nu)
\]

given by

\[
Q(\hat{\lambda}(x)) = \sum_{\mu \in P} \int_{\nu \in a_q^*} \pi_{\mu,i\nu}(x)D_{\mu,i\nu}^{-1}dm_\mu(\nu)
\]

for \( x \in D(G_q) \), where

\[
D_{\mu,i\nu} = \pi_{\mu,i\nu}(K_\mu \bowtie 1),
\]

and the measures \( dm_\mu \) on \( a_q^* \) are given by

\[
dm_\mu(\nu) = \frac{1}{|W|} \prod_{\alpha \in \Delta^+} \left| q^{\frac{1}{2}(\alpha,\rho+i\nu)} - q^{-\frac{1}{2}(\alpha,\rho+i\nu)} \right|^2 d\nu.
\]

Here \( d\nu \) denotes normalized Lebesgue measure on the torus \( a_q^* \).

For \( G_q = SL_q(2, \mathbb{C}) \) the formulas in Theorem 5.1 reduce to the result obtained by Buffenoir and Roche [3]. Buffenoir and Roche work with a different normalization of Lebesgue measure and a different parametrization of the irreducible representations, so that the formulas given in [3] look slightly different.

We will prove Theorem 5.1 by establishing the Plancherel formula

\[
\epsilon_{G_q}(f) = \sum_{\mu \in P} \int \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})dm_\mu(\nu)
\]

for elements of the form \( f = u_{ij}^\beta \otimes \omega_{kl}^\gamma \in C_c^\infty(G_q) \) with \( \beta, \gamma \in P^+ \). Since these elements span \( C_c^\infty(G_q) \) linearly this will yield the claim according to Lemma 1.2.

For notational convenience let us write

\[
\tau(f) = \sum_{\mu \in P} \int \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})dm_\mu(\nu)
\]

for the right hand side of the Plancherel formula. We will refer to the functional \( \tau : C_c^\infty(G_q) \to \mathbb{C} \) as the Plancherel functional.

**Lemma 5.2.** Let \( f = u_{ij}^\beta \otimes \omega_{kl}^\gamma \in C_c^\infty(G_q) \). Then

\[
\tau(f) = \dim_q(V(\gamma)) \sum_{w \in W} \sum_{r = u_i} \sum_{m}(\gamma)^{(w)} \phi(u_{im}^\beta S^{-1}(u_{mj}^\beta S^{-1}(u_{ik}^\beta u_{im}^\beta)q^{i.e.r,m}),
\]

where \( l(w) \) denotes the length of \( w \in W \).

**Proof.** From Theorem 3.2 and Theorem 3.3 we obtain

\[
\text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2}) = \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})
\]
for all $y \in W$, taking into account that the intertwiners between unitary principal series representations commute with the operators $D_{\mu,i\nu}^{-2}$. Using the Weyl denominator formula

$$
\prod_{\alpha \in \Delta^+} |q^{\frac{1}{2}(\alpha,\mu + i\nu)} - q^{-\frac{1}{2}(\alpha,\mu + i\nu)}|^2 = \sum_{x,y \in W} (-1)^{t(x)+t(y)} q^{(x+y,\mu)} q^{(x-y,\mu)}
$$

we therefore obtain

$$
\tau(f) = \frac{1}{|W|} \sum_{\mu \in P} \int_{t \in \mathfrak{t}} \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2}) \prod_{\alpha \in \Delta^+} |q^{\frac{1}{2}(\alpha,\mu + i\nu)} - q^{-\frac{1}{2}(\alpha,\mu + i\nu)}|^2 \, dv
$$

$$
= \frac{1}{|W|} \sum_{\mu \in P} \int_{t \in \mathfrak{t}} \int_{x,y \in W} \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})(-1)^{l(x)+l(y)} q^{(x+y,\mu)} q^{(x-y,\mu)} \, dv
$$

$$
= \frac{1}{|W|} \sum_{\mu \in P} \int_{t \in \mathfrak{t}} \int_{x,y \in W} \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})(-1)^{l(x)+l(y)} q^{(y^{-1}x+y,\mu)} q^{(y^{-1}x,\mu)} \, dv
$$

$$
= \sum_{\mu \in P} \int_{t \in \mathfrak{t}} \sum_{u \in W} \text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})(-1)^{l(w)} q^{(w,\mu)} q^{(w,\mu)} \, dv
$$

Inserting the formula

$$
\text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2}) = q^{(-2\mu,\mu)} \dim_q(V(\gamma)) \sum_{\epsilon_m = \mu} \sum_{r} \phi(u_{ir}^\gamma S^{-1}(u_{m_j}^\gamma) S^{-1}(u_{rk}^\gamma)) u_{im} \eta^{-(\nu,\epsilon_r)}
$$

for the twisted character $\text{tr}(\pi_{\mu,i\nu}(f)D_{\mu,i\nu}^{-2})$ from Proposition 3.5 we arrive at the claimed expression for the Plancherel functional.

Recall next the construction of the BGG complex for quantized universal enveloping algebras from [10]. For a dominant integral weight $\nu \in P^+$ and $k \geq 0$ set

$$
C_k = \bigoplus_{\nu \in W} M(w,\nu),
$$

where $M(\eta)$ denotes the Verma module of $U_q(\mathfrak{g})$ with highest weight $\eta \in P$ and $w,\nu = w(\nu + \rho) - \rho$

is the shifted Weyl group action.

Using inclusions of Verma modules, one constructs boundary operators $d : C_k \to C_{k-1}$ such that $d^2 = 0$ in the same way as for the original BGG complex. Let us also denote by $\epsilon_\nu : C_0 = M(\nu) \to V(\nu)$ the canonical projection, where $V(\nu)$ is the unique irreducible quotient of $M(\nu)$.

The following theorem is a special case of the results obtained by Heckenberger and Kolb in [11].

**Theorem 5.3.** The chain complex

$$
0 \to C_n \xrightarrow{d} C_{n-1} \xrightarrow{d} \cdots \xrightarrow{d} C_0 \xrightarrow{\epsilon_\nu} V(\nu) \to 0
$$

is exact.
We shall use the category equivalence between category and Harish-Chandra modules [11, 18] to transport the BGG-complex from Theorem 5.3 for $\nu = 0$ into a complex of principal series modules.

Following the notation and terminology in [18], let us fix $l = 0$ and denote by $\mathcal{I}$ the full subcategory of category consisting of modules whose weights all belong to $\mathcal{P} \subset \mathfrak{h}_q^*$. Also, let $HC_l$ be the full subcategory of Harish-Chandra bimodules for which the annihilator of the right action of $ZU_q(\mathfrak{g})$ contains the kernel of the central character associated with $l$. Since the weight $l = 0$ is dominant and regular the functor $\mathcal{F}_l : \mathcal{I} \to HC_l$ defined by

$$\mathcal{F}_l(M) = F \text{Hom}(M(l), M)$$

is an equivalence of categories, see section 5.5 in [18]. Using duality in category, we conclude that setting $D^k = \mathcal{F}_l (C^k_G)$ and $\partial = \mathcal{F}_l (d^k)$ yields an exact complex of Harish-Chandra modules.

More explicitly, setting

$$\mu = l - r, \quad \lambda + 2\rho = -l - r$$

where $l = 0$ and $r = w.0 = wp - \rho$ we get an isomorphism $F \text{Hom}(M(l), M(r)^\vee) \cong \Gamma(\mathcal{E}_{\mu, \lambda})$ of $\mathcal{D}(G_q)$-modules, so that

$$\mathcal{F}_l(M(w.0)^\vee) \cong \Gamma(\mathcal{E}_{-w.0,-w.0-2\rho})$$

Remark that $\mathcal{F}_l(M(0)^\vee) = \Gamma(\mathcal{E}_{0,-2\rho})$ contains the trivial $\mathcal{D}(G_q)$-module $\mathbb{C} \cong \mathcal{F}_l(V(0)^\vee)$ as a submodule. We thus arrive at the exact chain complex

$$0 \longrightarrow \mathbb{C} \overset{i}{\longrightarrow} D^0 \overset{\partial}{\longrightarrow} D^1 \overset{\partial}{\longrightarrow} \cdots \overset{\partial}{\longrightarrow} D^n \longrightarrow 0$$

of $\mathcal{D}(G_q)$-modules, where

$$D^j = \bigoplus_{w \in W} \Gamma(\mathcal{E}_{-w.0,-w.0-2\rho}).$$

We will refer to $D^\bullet$ as the geometric BGG complex. Let us point out that $D^\bullet$ is naturally a cochain complex, so that we are using cohomological indexing.

Now assume that $p = p \gg 1 \in \mathcal{D}(K_q) \gg \mathbb{C}^\infty(K_q) = \mathcal{D}(G_q)$ is a finite central projection, by which we mean that $p$ is supported on finitely many matrix blocks $K(V(\mu))$ inside $\mathcal{D}(K_q)$. Then the action of $p$ on the spaces $D^j$ determines direct summands $p \cdot D^j \subset D^j$ which assemble into a subcomplex $(p \cdot D^\bullet)^\bullet$ of the geometrical BGG-complex. Observe that $(p \cdot D^\bullet)^\bullet$ is in fact a finite dimensional exact complex of $p \mathcal{D}(G_q)p$-modules since all isotypical components of principal series modules are finite dimensional.

Recall the following basic fact from homological algebra. Assume that $C^\bullet$ is a finite dimensional complex of vector spaces, so that all the spaces $C^n$ are finite dimensional and $C^\bullet$ is supported in finitely many degrees. Moreover let $f : C^\bullet \to C^\bullet$ be a chain map, with induced maps $H^k(f) : H^k(C) \to H^k(C)$ on cohomology. Since the cohomology groups of $C^\bullet$ are finite dimensional as well we can form $\text{tr}(H^k(f))$, and we have the Hopf trace formula

$$\sum_{k \in \mathbb{Z}} (-1)^k \text{tr}_{H^k(C)}(H^k(f)) = \sum_{k \in \mathbb{Z}} (-1)^k \text{tr}_{C^k}(f^k),$$

where $\text{tr}_V$ denotes the natural trace on a vector space $V$.

Combining the above considerations we arrive at the following key lemma.

**Lemma 5.4.** Let $x \in \mathcal{D}(G_q)$. Then

$$\sum_{w \in W} (-1)^{l(w)} \text{tr}(\pi_{-w.0,-w.0-2\rho}(x)) = \hat{\epsilon}_{G_q}(x),$$
where \( \iota_{G_q} \) is the counit of \( \mathcal{D}(G_q) \).

**Proof.** Let us first point out that the operators \( \pi_{-w.0,-w.0-2p}(x) \) are finite rank, so that the left hand side of the above formula is well-defined.

Since the boundary operators in the geometric BGG complex are \( \mathcal{D}(G_q) \)-linear the endomorphism of \( D^* \) induced by \( x \) is a chain map. Note in addition that we can find a finite central projection \( p = p \propto 1 \in \mathcal{D}(G_q) = \mathcal{D}(K_q) \cong \mathcal{C}^\infty(K_q) \) such that \( x = pxp \). Hence the operator trace of \( \pi_{-w.0,-w.0-2p}(x) \) equals the trace of \( \pi_{-w.0,-w.0-2p}(pxp) \) viewed as endomorphism of the finite dimensional vector space \( p: \Gamma(\mathcal{E}.w.0,-w.0-2p) \). Now the Hopf trace formula applied to the complex \( (p \cdot D)^* \) yields the claim, using that the action of \( x \) on the trivial \( \mathcal{D}(G_q) \)-module \( C \subset D^0 \) is given by the counit \( \iota_{G} \).

Let us now go back to the problem of computing the Plancherel functional \( \tau(f) \) for an element of the form \( f = u_{ij}^\beta \otimes \omega_{kl}^\gamma \in \mathcal{C}^\infty(G_q) \). The following discussion completes the proof of Theorem 5.1.

**Theorem 5.5.** Let \( f = u_{ij}^\beta \otimes \omega_{kl}^\gamma \in \mathcal{C}^\infty(G_q) \). Then \( \tau(f) = \iota_{G_q}(f) \).

**Proof.** According to Lemma 5.2 we can write
\[
\tau(f) = \sum_{w \in W} (-1)^{(w)} \tau_w(f)
\]
where
\[
\tau_w(f) = \dim_q(V(\gamma)) \sum_{c_r = w.0} \phi(u_{i_r}^\beta, S^{-1}(u_{m_j}^\delta)S^{-1}(u_{rk}^\gamma)u_{km}^\beta)\eta_{c_r,c_m}
\]
\[
= \dim_q(V(\gamma)) \sum_{c_r = w.0, m,n} \phi(u_{i_r}^\beta, S^{-1}(u_{m_j}^\delta)S^{-1}(u_{rk}^\gamma)S(S^{-1}(u_{im}^\beta))(K_{-w.0}, S^{-1}(u_{mn}^\beta)))
\]
\[
= \dim_q(V(\gamma)) \sum_{c_r = w.0} \phi(u_{i_r}^\beta, \pi_{-w.0,-w.0-2p}(1 \otimes S^{-1}(u_{ij}^\beta))(S^{-1}(u_{rk}^\gamma))),
\]
using the definition of the Yetter-Drinfeld action of \( \mathcal{C}^\infty(K_q) \subset \mathcal{M}(\mathcal{D}(G_q)) \) on the principal series module \( \Gamma(\mathcal{E}.w.0,-w.0-2p) \) in the last step.

Note that the vectors \( e_{\nu}^{ab} = S^{-1}(u_{ma}^\nu) \) with \( \nu \in \mathcal{P}^+ \), \( e_{w.0} = u_{.0} \) and \( a \) arbitrary form a basis of \( \Gamma(\mathcal{E}.w.0,-w.0-2p) \). If we consider the linear functionals \( e_{\nu}^{ab} \) on \( \Gamma(\mathcal{E}.w.0,-w.0-2p) \) defined by
\[
e_{\nu}^{ab}(\xi) = q^{(2p,c_+)} \dim_q(V(\nu)) \phi(u_{ab}^\nu \xi),
\]
then we obtain
\[
e_{\eta}^{cd}(e_{ab}^{\nu}) = q^{(2p,c_+)} \dim_q(V(\nu)) \phi(u_{cd}^\eta S^{-1}(u_{ba}^\nu ))
\]
\[
= q^{(2p,c_+)} \dim_q(V(\nu)) \phi(u_{cd}^\eta S(u_{ba}^\nu ))
\]
\[
= \delta_{\eta d} \delta_{c_+} \delta_{ab}
\]
for any \( \eta, \nu \in \mathcal{P}^+ \) and \( a, b, c, d \) according to the Schur orthogonality relations. It follows that the vectors \( e_{\eta}^{ab} \) are the dual basis vectors to the vectors \( e_{\nu}^{ab} \).

Observe next that the action of \( S^{-2}(\omega_{kl}^\gamma) \otimes 1 \in \mathcal{D}(G_q) \) on \( \Gamma(\mathcal{E}.w.0,-w.0-2p) \) is given by
\[
\pi_{-w.0,-w.0-2p}(S^{-2}(\omega_{kl}^\gamma) \otimes 1)(e_{ab}^{\nu}) = \pi_{-w.0,-w.0-2p}(S^{-2}(\omega_{kl}^\gamma) \otimes 1)(S^{-1}(u_{rs}^\eta ))
\]
\[
= \sum_{i} (S^{-1}(\omega_{kl}^\gamma), S^{-1}(u_{rs}^\eta ))S^{-1}(u_{rk}^\eta )
\]
\[
= \delta_{\gamma r} \delta_{sl} S^{-1}(u_{rk}^\eta ) = \delta_{\gamma r} \delta_{sl} e_{kr}^\eta .
\]
We shall now assemble these considerations. More precisely, let us consider the element \( x \in \mathcal{D}(G_q) \) defined by
\[
x = q^{(-2p,\epsilon_1)} S^{-2}(\omega^2_{kl}) \propto S^{-1}(u^\beta_{ij}) = q^{(-2p,\epsilon_1)} (S^{-2}(\omega^2_{kl}) \propto 1) (1 \propto S^{-1}(u^\beta_{ij})).
\]
Then by combining the above formulas we compute
\[
\text{tr}(\pi_{-w,0,-w,0-2\rho}(x)) = \sum_{\eta \in \mathbf{P}^+} \sum_{\epsilon_r = w, 0} \sum_{s} \epsilon_{fr}^s (\pi_{-w,0,-w,0-2\rho}(x)(e_{fr}^s))
\]
\[
= q^{(-2p,\epsilon_1)} \sum_{\epsilon_r = w, 0} \epsilon_{fr}^r (\pi_{-w,0,-w,0-2\rho}(1 \propto S^{-1}(u^\beta_{ij}))(e_{fr}^r))
\]
\[
= \dim_q(V(\gamma)) \sum_{\epsilon_r = w, 0} \phi(u^\gamma_{fr}, \pi_{-w,0,-w,0-2\rho}(1 \propto S^{-1}(u^\beta_{ij}))(S^{-1}(u^\gamma_{fr})))
\]
\[
= \tau_w(f).
\]
Applying the Hopf trace formula from Lemma 5.4, we conclude that \( \tau(f) \) is equal to \( \hat{\epsilon}_{G_q}(x) \). In other words, we obtain
\[
\tau(f) = \hat{\epsilon}_{G_q}(x) = \delta_{ij} \delta_{\gamma 0} = \epsilon_{G_q}(f)
\]
as desired. \( \square \)

Let us remark that the Plancherel measure for \( G_q \) resembles its counterpart for the classical group \( G \). More precisely, up to a normalization the classical measure is given by
\[
\prod_{\alpha \in \Delta^+} |(\alpha, \mu + i\nu)|^2 d\nu = \prod_{\alpha \in \Delta^+} (\alpha, \mu + i\mu)(\alpha, \mu - i\mu) d\nu
\]
in the component of the parameter space \( \mathbf{P} \times \mathbf{a}^* \) corresponding to \( \mu \in \mathbf{P} \), compare section 5 in [9]. By comparison, the measure in Theorem 5.1 reads
\[
dm_\mu(\nu) = \frac{1}{|W|} \prod_{\alpha \in \Delta^+} |q^{\frac{1}{2}(\alpha, \mu + i\nu)} - q^{-\frac{1}{2}(\alpha, \mu + i\nu)}|^2 d\nu
\]
\[
= \frac{1}{|W|} \prod_{\alpha \in \Delta^+} (q - q^{-1})^2 |\frac{1}{2}(\alpha, \mu + i\mu)| |\frac{1}{2}(\alpha, \mu - i\mu)| d\nu.
\]
Expanding \( q = e^h \) in powers of \( h \) this can be rewritten as
\[
dm_\mu(\nu) = \frac{1}{|W|} \prod_{\alpha \in \Delta^+} (q^{(\mu, \alpha)} + q^{-\mu, \alpha}) - q^{(i\nu, \alpha)} - q^{-(i\nu, \alpha)} d\nu
\]
\[
= \frac{1}{|W|} \prod_{\alpha \in \Delta^+} h^2 (\alpha, \mu + i\nu)(\alpha, \mu - i\nu) d\nu + \text{ higher order terms.}
\]
That is, up to a scalar, the first nonzero coefficient in the expansion agrees with the formula for the classical measure.

6. Further remarks on the main result

In this section we include a few supplementary remarks on computational aspects of the formulas obtained in Theorem 5.5.

Let \( \nu \in \mathbf{P}^+ \) and let \( e^s_{1}, \ldots, e^s_{\nu_0} \) be an orthonormal weight basis of \( V(\nu) \). Moreover denote by \( e^{\mu}_{1}, \ldots, e^{\mu}_{\nu_0} \) the dual basis of the contragredient representation \( V(\nu)^* = \text{Hom}(V(\nu), \mathbb{C}) \). Inspecting Lemma 5.2 and the definition of the Haar functional, the computation of the Plancherel functional \( \tau(f) \) for all \( f \) of the form \( f = u^\gamma_{ij} \otimes \omega^\gamma_{kl} \) with fixed \( \beta, \gamma \in \mathbf{P}^+ \) can be rephrased in terms of the tensor
\[
\tau_{\gamma \beta} = \sum_{w \in W} \sum_{\epsilon_r = w, \rho - \mu} \sum_m (-1)^{(w)} q^{(\epsilon_r, \epsilon_m - 2\rho)} P(e^\gamma_{ij} \otimes e^\beta_{ij} \otimes e^\epsilon_r \otimes e^\epsilon_m),
\]
where $P$ denotes the orthogonal projection onto the trivial isotypical component of the tensor product $V(\gamma) \otimes V(\beta) \otimes V(\gamma^*) \otimes V(\beta^*)$. More precisely, the nontrivial part of Theorem 5.5, namely the vanishing of all $\tau(f)$ for all $f = u_0^\gamma \otimes \omega_1^\delta$ with $\gamma \neq 0$, is equivalent to the following assertion.

**Theorem 6.1.** For all $\beta, \gamma \in P^+$ with $\gamma \neq 0$ we have $\tau_{\beta\gamma} = 0$.

Except in a few special cases, it seems a forbidding task to compute any of the summands appearing in the tensor $\tau_{\beta\gamma}$ explicitly.

However, let us restrict attention to the case of the quantum Lorentz group $G_q = SL_q(2, \mathbb{C})$ and explain how to verify Theorem 6.1 by elementary calculations in this case nonetheless. This yields a shorter proof of the Plancherel formula than the original one by Buffenoir and Roche [4], and does not invoke any homological algebra arguments.

We identify the set of weights $\mathbf{P}$ of $K_q = SU_q(2)$ with $\frac{1}{2}\mathbb{Z}$. Moreover we shall work with the orthonormal basis $e_j^\nu$ for $j \in \{-\nu, -\nu + 1, \ldots, \nu\}$ of the irreducible representation $V(\nu)$ of highest weight $\nu \in \frac{1}{2}\mathbb{N}_0$ as in [15]. Explicitly, we have

$$E \cdot e_j^\nu = q^j[\nu - j + 1]\frac{1}{q}\beta^{\nu+1}_j,$$

$$F \cdot e_j^\nu = q^{-(\nu+1)}[\nu + j + 1]\frac{1}{q}\beta^{-\nu-1}_j,$$

where we interpret $e_j^\nu = 0$ if $|j| > \nu$, and we abbreviate $E = E_1, F = F_1$. For the dual basis vectors $e_j^\nu \in V(\nu^*)$ in the contragredient representation we obtain

$$E \cdot e_j^\nu = -q^{-j+1}[\nu - j + 1]\frac{1}{q}\beta^{\nu-1}_j,$$

$$F \cdot e_j^\nu = -q^{j}[\nu + j + 1]\frac{1}{q}\beta^{j+1}_j.$$

Using these formulas we shall verify the following relation, where we write again $P$ for the projection onto the trivial isotypical component.

**Lemma 6.2.** Let $\beta, \gamma \in \frac{1}{2}\mathbb{N}_0$. If $\gamma > 0$ then

$$\sum_m q^{-2m(r+1)+2} P(e_{r-1}^\gamma \otimes e_m^\beta \otimes e_{-1}^\gamma \otimes e_\beta^m) = \sum_m q^{-2mr} P(e_m^\beta \otimes e_m^\gamma \otimes e_\gamma^m \otimes e_\beta^m)$$

for all $r \in \{-\gamma + 1, -\gamma + 2, \ldots, \gamma\}$.

**Proof.** Let us consider the relation

$$0 = \sum_{m \in \mathbf{P}} q^{-2(m-1)r} P(E \cdot (e_{r-1}^\gamma \otimes e_m^\beta \otimes e_\gamma^m \otimes e_\beta^m)),$$

obtained from the fact that $E$ acts by zero on the trivial representation. We calculate

$$q^{-2(m-1)r} (E \cdot e_{r-1}^\gamma \otimes (K^2 \cdot e_m^\beta) \otimes (K^2 \cdot e_\gamma^m) \otimes (K^2 \cdot e_\beta^m)) = q^{-2m}q^{-2r}q^{-1}\gamma - r + 1\frac{1}{q}\beta^{\gamma-1}_r e_r^\gamma \otimes e_m^\beta \otimes e_\gamma^m \otimes e_\beta^m$$

$$= q^{-2mr} q^{-1}\gamma - r + 1\frac{1}{q}\beta^{\gamma-1}_r e_r^\gamma \otimes e_m^\beta \otimes e_\gamma^m \otimes e_\beta^m,$$

using the notation $K^2 = K_1$. Similarly,

$$q^{-2(m-1)r} (1 \otimes (e_m^\beta) \otimes (K^2 \cdot e_\gamma^m) \otimes (K^2 \cdot e_\beta^m))$$

$$= -q^{-2m}q^{-r+1}\gamma - r + 1\frac{1}{q}\beta^{\gamma-1}_r e_r^\gamma \otimes e_m^\beta \otimes e_\gamma^m \otimes e_\beta^m$$

$$= -q^{-2m}q^{r+1}\gamma - r + 1\frac{1}{q}\beta^{\gamma-1}_r e_r^\gamma \otimes e_m^\beta \otimes e_\gamma^m \otimes e_\beta^m.$$
Moreover we have
\[
\sum_m q^{-2(m-1)r} (1 \cdot e^\gamma_{r-1}) \otimes (E \cdot e^\beta_m) \otimes (K^2 \cdot e^\gamma_r) \otimes (K^2 \cdot e^m)
\]
\[
+ q^{-2(m-1)r} (1 \cdot e^\gamma_{r-1}) \otimes (1 \cdot e^\beta_m) \otimes (E \cdot e^m)
\]
\[
= \sum_m q^{-2(m-1)r} q^{-2r} q^{-2m} [\beta - m + 1] \frac{1}{2} e^\gamma_{r-1} \otimes e^\beta_m \otimes e^\gamma_r \otimes e^m
\]
\[
- q^{-2(m-1)r} q^{-m+1} [\beta - m + 1] \frac{1}{2} e^\gamma_{r-1} \otimes e^\beta_m \otimes e^\gamma_r \otimes e^{m-1}
\]
\[
= \sum_m q^{-2(m-1)r} q^{-2r} q^{-m} [\beta - m + 1] \frac{1}{2} e^\gamma_{r-1} \otimes e^\beta_m \otimes e^\gamma_r \otimes e^m
\]
\[
- q^{-2m} q^{-m} [\beta - m + 1] \frac{1}{2} e^\gamma_{r-1} \otimes e^\beta_m \otimes e^\gamma_r \otimes e^m
\]
\[
= 0.
\]
Combining these relations yields the claim. \[\square\]

We may now compute \(\tau_{\beta\gamma}\) for all \(\beta, \gamma \in \frac{1}{2}\mathbb{N}_0\) with \(\gamma > 0\). More precisely, according to Lemma 5.2 we obtain
\[
\tau_{\beta\gamma} = \sum_m P(e^\gamma_m \otimes e^\beta_m \otimes e^\gamma_0 \otimes e^m_0) - \sum_m q^{-2m+2} P(e^\gamma_1 \otimes e^\beta_m \otimes e^\gamma_0 \otimes e^m_0) = 0.
\]
This proves Theorem 6.1 in rank 1, and therefore also the Plancherel formula for the quantum group \(G_q = SL_q(2, \mathbb{C})\).

7. The reduced \(C^*\)-algebras of complex quantum groups

In this section we use the Plancherel Theorem 5.1 to describe the structure of the reduced group \(C^*\)-algebras of complex quantum groups, in analogy with the classical case.

Let \(G_q\) be a complex semisimple quantum group. Moreover let \(\mathcal{H} = (\mathcal{H}_{\mu,\lambda})_{\mu,\lambda}\) be the locally constant Hilbert space bundle of unitary principal series representations of \(G_q\) over \(P \times t_q\). By slight abuse of notation we will also write \(\mathcal{H}\) for the corresponding Hilbert \(C_0(P \times t_q)\)-module. Inspecting the explicit formulas for the action of \(\mathcal{D}(G_q)\) on unitary principal series representations we obtain a nondegenerate \(*\)-homomorphism \(\pi : \mathcal{D}(G_q) \to C_0(P \times t_q, K(\mathcal{H}))\) by setting \(\pi(x)_{(\mu, \lambda)} = \pi_{\mu,\lambda}(x)\). Here \(C_0(P \times t_q, K(\mathcal{H}))\) denotes the \(C_0(P \times t_q)\)-algebra of compact operators on the Hilbert \(C_0(P \times t_q)\)-module \(\mathcal{H}\). By the definition of the maximal group \(C^*\)-algebra \(C^*_r(G_q)\), the map \(\pi\) extends uniquely to a nondegenerate \(*\)-homomorphism \(C^*_r(G_q) \to C_0(P \times t_q, K(\mathcal{H}))\), which will again be denoted by \(\pi\), and which we will refer to as the canonical \(*\)-homomorphism below.

We obtain an action of \(W\) on \(C_0(P \times t_q, K(\mathcal{H}))\) by
\[
(w \cdot f)(\mu, \lambda) = U(w)_{\mu,\lambda} f(w^{-1} \mu, w^{-1} \lambda) U(w)_{\mu,\lambda}^*.
\]
where \(U(w)_{\mu,\lambda} : \mathcal{H}_{w^{-1} \mu, w^{-1} \lambda} \to \mathcal{H}_{\mu,\lambda}\) is a unitary intertwiner as in Theorem 3.3. Using the explicit construction of intertwiners associated to simple reflections in chapter 5 of [18] one checks that this is indeed a well-defined action, noting that conjugation by \(U(w)_{\mu,\lambda}\) eliminates the scalar ambiguity in the definition of the intertwiners.

With this notation and terminology in place the structure of \(C^*_r(G_q)\) can be described as follows.

**Theorem 7.1.** Let \(G_q\) be a complex semisimple quantum group, and let \(\mathcal{H} = (\mathcal{H}_{\mu,\lambda})_{\mu,\lambda}\) be the Hilbert space bundle of unitary principal series representations of \(G_q\) over \(P \times t_q\). Then one obtains an isomorphism
\[
C^*_r(G_q) \cong C_0(P \times t_q, K(\mathcal{H}))^W
\]
induced by the canonical $*$-homomorphism $\pi : C^{*}_t(G_q) \to C_0(\mathbb{P} \times t^*_q, \mathbb{K}(\mathcal{H}))$.

Proof. According to the Plancherel Theorem 5.1, all unitary principal series representations of $\pi$ factorize over the reduced group $C^*$-algebra, and the resulting $*$-homomorphism $\pi : C^{*}_t(G_q) \to C_0(\mathbb{P} \times t^*_q, \mathbb{K}(\mathcal{H}))$ is injective. The image $\text{im}(\pi)$ of the map $\pi$ is contained in $C_0(\mathbb{P} \times t^*_q, \mathbb{K}(\mathcal{H}))^W$ by construction.

It remains to show that $\text{im}(\pi)$ is in fact equal to $C_0(\mathbb{P} \times t^*_q, \mathbb{K}(\mathcal{H}))^W$. Note that the irreducible representations of $A = C_0(\mathbb{P} \times t^*_q, \mathbb{K}(\mathcal{H}))^W$ are given by point evaluations on $\mathbb{P} \times t^*_q$, and these remain irreducible when restricted to the image of $\pi$. Moreover, two irreducible representations of $A$ are inequivalent if they correspond to parameters in different orbits of the Weyl group action on $\mathbb{P} \times t^*_q$. According to Theorem 5.3, the same condition distinguishes unitary principal series representations. Hence Dixmier’s version of the Stone-Weierstrass Theorem, see section 11.1 in [7], yields the claim. \hfill \Box

Theorem 7.4 shows in particular that the trivial representation of $G_q$ does not factorize through $C^{*}_t(G_q)$. In other words, the full and reduced group $C^*$-algebras of $G_q$ are not isomorphic, which means that $G_q$ is not amenable [3]. More interestingly, Arano has shown [2, 10] that higher rank complex quantum groups do in fact have property (T).

Finally, let us point out that Theorem 7.4 illustrates nicely the deformation aspect of the theory of complex semisimple quantum groups, a feature which is not apparent from the Drinfeld double construction. Indeed, by setting formally $h = 0$ and $t^*_q = t^*$ in Theorem 7.4, we reobtain the well-known description of the reduced group $C^*$-algebra of the classical complex semisimple Lie group $G$. Thus the limit $q \to 1$ corresponds to the opening of the torus $t^*_q = t^*/i\hbar^{-1}\mathbb{Q}$ to $t^*$ as $h \to 0$.
