Abstract

We investigate the $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions within a coupled-channels effective-Lagrangian method which is based on the $K$-matrix approach. The two-body final channels included are $\pi N$, $\eta N$, $\phi N$, $\rho N$, $\gamma N$, $K \Lambda$, and $K \Sigma$. Non-resonant meson-baryon interactions are included in the model via nucleon intermediate states in the $s$- and $u$-channels and meson exchanges in the $t$-channel amplitude and the $u$-channel resonances. The nucleon resonances $S_{11}(1535)$, $S_{11}(1650)$, $S_{31}(1620)$, $P_{11}(1440)$, $P_{11}(1710)$, $P_{13}(1720)$, $P_{33}(1232)$, $P_{33}(1600)$, $D_{13}(1520)$, $D_{13}(1700)$, and $D_{33}(1700)$ are included explicitly in the calculations. With a single parameter set which was derived earlier from our analysis of the $\eta$ meson photoproduction, the model describes well all the available cross section and polarization data of the SAPHIR collaboration for the two investigated channels. The description of the data of the CLAS collaboration, however, is not of the same quality. In contrast to some previous studies, we do not find any compelling need for including a $D_{13}$ state with mass of around 2.0 GeV in order to reproduce the data for the $p(\gamma, K^+)\Lambda$ reaction at photon energies corresponding to the invariant mass around 1.9 GeV.

I. INTRODUCTION

Recently, several laboratories have devoted considerable amount of effort to the investigation of the photoproduction of strangeness on the nucleon. Experiments performed at JLab-CLAS [1, 2], ELSA-SAPHIR [3, 4] and SPring8/LEPS [5, 6] have produced high quality data on the associate strangeness production reactions $p(\gamma, K^+\Lambda)$ and $p(\gamma, K^+\Sigma^0)$ covering the photon energy regime from threshold to upto 3.0 GeV. Furthermore, data on single and double polarization [7] observables have also become available. The motivation behind these studies has been the fact that a considerable part of the excitation spectrum of the nucleon can, in principle, participate in the production process of associated strangeness ($K^+\Lambda$ and $K^+\Sigma^0$) through these reactions because even at the threshold they involve invariant masses that exceed those of several baryonic resonances. It is hoped that these studies could help in investigating the so-called missing baryonic resonances that are predicted by the quark models (see, e.g., Ref. [8]) but not observed in non-strange meson photoproduction. Some of these resonances may couple strongly to the $K\Lambda$ and $K\Sigma$ channels.

The determination of the properties of the nucleon resonances (e.g., their masses, widths, and coupling constants to various decay channels) is an important issue in hadron physics. This will help in testing the predictions of lattice quantum chromodynamics (LQCD) which is the only theory that tries to calculate these properties from first principles. Even though, the requirement of computational power is enormous for their numerical realization, such calculations have started to provide results for the properties of nucleon ground as well as excited states [9–13]. Furthermore, reliable nucleon resonance data are important for testing the "quantum chromodynamics (QCD) based" quark models of the nucleon (see, e.g., [8, 14]) and also the dynamical coupled-channels models of baryonic resonances [15].

One of the major challenges of this field is the extraction of reliable information about nucleon resonance properties from the photoproduction data. In experiments, these resonances are excited as intermediate states before decaying into the final meson and baryon channels. A good description of intermediate-energy scattering is still not amenable to the LQCD calculations. Therefore, at this stage the effective methods are usually employed to describe the dynamics of the meson production reactions. Baryon resonance states are included explicitly in these approaches and their properties are obtained by comparing the predictions of the theory with the experimental data [16–21].
In order to determine resonance properties reliably from the experimental measurements one requires a model that can analyze the different reactions over the entire energy range using a single Lagrangian density that generates all non-resonance contributions from Born, $u$- and $t$-channel contributions without introducing new parameters. At the same time, the Lagrangian should also satisfy the symmetries of the fundamental theory (i.e. QCD) while retaining only mesons and baryons as effective degrees of freedom.

The coupled-channels method within the $K$-matrix approach \cite{22–28} provides a way to analyze simultaneously all reaction data for a multitude of observables in different reaction channels while respecting the constraints described above. This method is attractive because it is based on an effective-Lagrangian framework that is gauge invariant and is consistent with chiral symmetry. It also provides a convenient way of imposing the unitarity constraint. This results from the Bethe-Saltpeter equation in the approximation where particles forming the loop are taken on the mass shell i.e. only the discontinuity part of the loop integral is retained. The $S$ matrix in this approach is unitary provided the $K$-matrix is taken to be real and Hermitian.

Alternatively, the dynamical coupled channels models within the Hamiltonian formalism have also been used to describe the meson-production reactions \cite{29–35}. Isobaric models such as Kaon-Maid \cite{36} and Saclay-Lyon \cite{37} have been utilized in Ref. \cite{38, 39} to describe the $p(\gamma, K^+)\Lambda$ reaction. This reaction has also been studied within a variety of tree-level isobar models \cite{40–43} and in the quark models \cite{44–46}. In Ref. \cite{47} a gauge-invariant chiral unitary framework is used to describe the photoproduction data of both SAPHIR and CLAS collaborations.

The main objective of this paper is to study photoproduction reactions $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ for photon energies ranging from threshold to about 3 GeV in a coupled-channels formalism of Refs. \cite{25, 27, 28} which is based on the $K$-matrix approach. This is an effective Lagrangian model which is gauge invariant and obeys the low-energy theorem. We aim at describing simultaneously the data on total and differential cross sections as well as on polarization observables for both the reactions within the same framework with a single parameter set. The $\Lambda$ and $\Sigma^0$ hyperons have isospins of 0 and 1, respectively. Thus, the intermediate states of $K^+\Lambda$ have the isospin $\frac{1}{2}$ only ($N^*$) while those of $K^+\Sigma^0$ can have both $\frac{1}{2}$ and $\frac{3}{2}$ isospins ($N^*$ and $\Delta$). Therefore, a combined description of all the available data for both these channels is indeed quite interesting and is a challenge to any theoretical model.
We would like to add that a subset of SAPHIR and CLAS data for the $p(\gamma, K^+)\Lambda$ reaction has been investigated previously in Ref. [26] within the Giessen model which is also a coupled-channels effective-Lagrangian K-matrix approach. Despite some differences in details (see the discussions in Ref. [28]), our method is similar to that of the Giessen model. The calculations presented in Ref. [26] have reproduced the $p(\gamma, K^+)\Lambda$ data well with a slight preference to the SAPHIR data. In the present work we have attempted to describe the $p(\gamma, K^+)\Sigma^0$ reaction also along with the $p(\gamma, K^+)\Lambda$ one within the same framework using the same parameter set which already makes our analysis self-contained. Nevertheless, by comparing our results with those of the Giessen model we expect to gain further insight in the mechanism of the strangeness photoproduction off proton.

Our paper is organized in the following way. An overview of our model is given in section II. This consists of a short discussion of the K-matrix formalism, the model space and the channels included, the Lagrangians, and the form factors. Our results and their discussions are presented in section III. Summary and conclusions of our work are presented in section IV. Finally form of Lagrangians at various vertices are given in appendix A.

II. DESCRIPTION OF THE MODEL

This work is based on an effective-Lagrangian model. The kernel in the K-matrix approach is built by using the effective Lagrangian as given in Appendix A. We have taken into account contributions from (i) the nucleon Born term, (ii) $t$-channel exchanges of mesons, (iii) nucleon and resonance terms in the $u$-channel, and (iv) baryonic resonance in the $s$-channel (see Fig. 1). The sum of amplitudes (i), (ii) and (iii) is termed as the background contribution. As is discussed below, this approach allows to account for coupled-channels effects while preserving many symmetries of a full field-theoretical method.

A. K-matrix model

The coupled-channels (or re-scattering) effects are included in our model via the K-matrix formalism. In this section we present a short overview of this approach; a more detailed description can be found in Refs. [23, 25, 48, 49].
FIG. 1: [color online] Feynman diagrams included in this work. First row: $s$- and $u$-channel diagrams with propagating final state baryons ($B = N, \Lambda, \Sigma$) or intermediate state resonances ($\Delta, N^*$). $M$ stands for mesons included in the model space. Second row: $t$-channel contributions with propagating asymptotic and intermediate mesons, and the contact term required by the gauge invariance.

In the K-matrix formalism the scattering matrix is written as

$$T = \frac{K}{1 - iK}. \quad (1)$$

It is easy to check that the resulting scattering amplitude $S = 1 + 2iT$ is unitary provided that $K$ is Hermitian. The construction in Eq. (1) can be regarded as the re-summation of an infinite series of loop diagrams by making a series expansion,

$$T = K + iKK + i^2KKK + \cdots. \quad (2)$$

The product of two $K$-matrices can be rewritten as a sum of different one-loop contributions (three- and four-point vertex and self-energy corrections) depending on Feynman diagrams that are included in the kernel $K$. However, not the entire spectrum of loop corrections present in a true field-theoretical approach, is generated in this way and the missing ones should be accounted for in the kernel. In constructing the kernel, care should be taken to avoid double counting. For this reason we include in the kernel tree-level diagrams only [Figs. 1(a)-1(c)], modified with form-factors and contact terms [Fig. 1(d)]. The contact

Terms (or four-point vertices) ensure gauge invariance of the model and express model-dependence in working with form factors (see Section II C). Inclusion of both s- and u-channel diagrams [Figs 1(a) and 1(b), respectively] in the kernel insures the compliance with crossing symmetry.

To be more specific, the loop corrections generated in the K-matrix procedure include only those diagrams which correspond to two on-mass-shell particles in the loop [50, 51]. This is the minimal set of diagrams one has to include to ensure two-particle unitarity. Thus, all diagrams that are not two particle reducible (e.g. $\gamma N \rightarrow 2\pi N$ channels), are not included. In addition, only the convergent pole contributions i.e. the imaginary parts of the loop correction, are generated. The omitted real parts are important to guarantee analyticity of the amplitude and may have complicated cusp-like structures at energies where other reaction channels open. In principle, these can be included as form factors as is done in the dressed K-matrix procedure [50, 52]. We have chosen to work with purely phenomenological form factors for the reason of simplicity. An alternative procedure to account for the real-loop corrections is offered in Refs. [53–55].

The strength of the K-matrix procedure is that in spite of its simplicity, several symmetries are obeyed by it [48]. As was already noted, the resulting amplitude is unitary provided that K is Hermitian, and it obeys gauge invariance provided the kernel is gauge-invariant.
In addition, the scattering amplitude complies with crossing symmetry when the kernel is crossing symmetric. This property is crucial for a proper behavior of the scattering amplitude in the low-energy limit [51, 56]. Coupled-channels effects are automatically accounted for by this approach for the channels explicitly included into the $K$-matrix as the final states.

As a result of this channel coupling, the resonances generate widths which are compatible with their decays to channels included in the model space. For some resonances, such as the $\Delta$ and the $S_{11}(1535)$, this corresponds to their total width. Other resonances, particularly the high lying ones, may have important decay branches to states that are not included in the model basis. To account for this in our calculations, we have added an explicit dissipative part to the corresponding propagators. The magnitudes of these widths are equivalent to decay widths of the resonances to states outside of our model space.

The resonances which are taken into account in building the kernel are summarized in Table I. In the current work we limit ourselves to the spin-$\frac{1}{2}$ and spin-$\frac{3}{2}$ resonances as in this energy regime higher spin resonances are known [26] to give only a minor contribution to the $K^+\Lambda$ channel. Spin-$\frac{3}{2}$ resonances are included with so-called gauge-invariant vertices which have the property that the coupling to spin-$\frac{1}{2}$ pieces in the Rarita-Schwinger propagator vanish [50, 57, 58]. We have chosen this prescription since it reduces the number of parameters as we do not have to deal with the off-shell couplings. The effects of these off-shell couplings can be absorbed in contact terms [58] which we prefer, certainly within the context of the present work.

The masses of the resonances given in Table I are bare masses and they thus may deviate from the values given by the Particle Data Group [59]. Higher-order effects in the $K$-matrix formalism do give rise to a (small) shift of the pole-position with respect to the bare masses. The masses of very broad resonances, in particular the $P_{11}$, are not well determined - values lying in a broad range (typically a spread of the order of a quarter of the width) give comparable results. The width quoted in Table I corresponds to the partial width for decay to states outside our model space. The parameters as quoted in Table I are mostly unchanged as compared to those presented in previous calculations within this model [25, 27, 28]. The $t$-channel contributions which are included in the kernel, are summarized in Table II.
TABLE II: Mass, spin, parity and isospin of the mesons which are included in the model. The rightmost column specifies in which reaction channels their $t$-channel contribution are taken into account.

| Meson | M [GeV] | $S^\pi$ | I | $t$-ch contributions |
|-------|---------|--------|---|----------------------|
| $\pi$ | 0.135   | 0$^-$  | 1 | $(\gamma N \rightarrow \phi N), (\pi N \rightarrow \rho N)$ |

| $\sigma$ | 0.760  | 0$^+$  | 0 | $(N\gamma \rightarrow K\Lambda), (N\gamma \rightarrow K\Sigma)$, $(K\Lambda \rightarrow N\eta), (K\Sigma \rightarrow N\eta), (N\pi \rightarrow K\Sigma)$ |

B. Model space, channels included

To keep the model manageable and relatively simple, we consider only stable particles or narrow resonances in two-body final states. The $\Lambda K$, $\Sigma K$, $N\phi$, $N\eta$ and $N\gamma$ are the final states of primary interest, and the $N\pi$ final state is included for its strong coupling to most of the resonances. Three-body final states, such as $2\pi N$, are not included explicitly as stated above. Their influence on widths of resonances is taken into account by assigning an additional (energy dependent) width to them [23]. To investigate the effects of coupling to more complicated states, we have also included the $N\rho$ final state. As was shown in Ref. [25], inclusion of the $\rho$ channel has a strong influence on the pion sector but only a relatively minor effect on $\Lambda$ and $\Sigma$ photoproduction.

The components of the kernel which couple the different non-electromagnetic channels are taken as the sum of tree-level diagrams, similar to what is used for the photon channels. For these other channels no additional parameters were introduced and they thus need no
further discussion.

C. Form-factors & gauge restoration

Without the introduction of form factors, calculations with Born terms strongly overestimates the cross section at higher energies. Although inclusion of coupled-channels effects reduces the cross section at high energies yet disagreement with the experimental data still persists. Therefore, the Born contribution will have to be quenched with form factors. There are two physical motivations for introducing form factors (or vertex functions). First of all, at high photon energies one may expect to become sensitive to the short-range quark structure of the nucleon. Because this physics is not included explicitly in our model, we can only account for it through the introduction of phenomenological vertex functions. The second reason has to do with the intermediate-range effects because of meson-loop corrections which are not generated through the K-matrix formalism. Examples of these are given in Refs. [50, 52].

In our approach as well as that of Ref. [24], the form-factors are not known a priori and thus they introduce certain arbitrariness in the model. In the current paper we limit ourselves to dipole form-factors in s-, u- and t-channels because of their simplicity,

\[ F_m(s) = \frac{\lambda^2}{\lambda^2 + (s - m^2)^2}, \]  

where \( m \) is the mass of the propagating particle and \( \lambda \) is the cut-off parameter. For ease of notation we introduce the subtracted form factors

\[ \tilde{f}_m(s) = \frac{1 - F_m(s)}{s - m^2}, \]  

where \( F_m(s) \) is normalized to unity on the mass-shell, \( F_m(m^2) = 1 \), and \( \tilde{f}_m(m^2) \) is finite.

However, only in the kaon sector we use a different functional form for the u-channel form-factors

\[ H_m(u) = \frac{u\lambda^2}{(\lambda^2 + (u - m^2)^2)m^2}. \]  

The argumentation for this different choice is presented in the discussion of the \( \Sigma \)-photoproduction results in Ref. [25]. Often a different functional form and cut-off values are introduced for the t-channel form factors. Although this can easily be motivated, it introduces additional model dependence and increases the number of free parameters. To
limit the overall number of parameters we have taken the same cut-off value $[\lambda = 1.2 \text{ GeV}^2$, see Eq. (3)] for all form-factors except for the Born contributions in kaon channels where we used $\lambda = 1.0 \text{ GeV}^2$.

Inclusion of form-factors will in general break electromagnetic gauge-invariance of the model. Therefore, a gauge-restoration procedure should be applied. In Ref. [25], the implications of various gauge-restoration procedures was studied for the $\gamma p \rightarrow K\Sigma$ amplitude. It was observed that the gauge-invariance restoration procedure is model dependent which may give rise to strongly different Born contributions to the amplitude. Therefore, the choice of a procedure to be adopted is guided by its ability to describe the experimental data. It was found that the gauge-restoration procedure of Davidson and Workman [60] provided the best description of the data on the $K\Sigma$ photoproduction. We have used this procedure in the present work also.

We note that fitting the pion-scattering and pion-photoproduction amplitudes fixes masses as well as pion- and photon-coupling constants for most of the resonances. This limits strongly the number of free parameters for the kaon-production channels.

### III. RESULTS AND DISCUSSIONS

Our aim in this paper is to use the data base on $p(\gamma, K^+)^A$ and $p(\gamma, K^+)^A\Sigma^0$ reactions of both SAPHIR and CLAS collaborations to check various ingredients of our unitary coupled-channels field theoretic model of meson production in photon induced reactions on nucleons. In particular we are interested in checking to what extent a simultaneous fit to data for a multitude of observables for both the reactions can be obtained with a single set of input parameters. This is expected to provide a strong constraint on the model parameters thus reducing the model dependence to a minimum. It is also likely to highlight the role of channel couplings in various regions of photon energies because several calculations of the associated kaon production reactions have neglected these effects.

We emphasize however, that even the large experimental data base may not allow to fix the extracted parameters uniquely within the unitary coupled-channels effective-Lagrangian model [24]. This is due to the fact that it is necessary to include empirical form factors in the model to regularize the amplitudes at higher energies. As mentioned before These form factors require a gauge-invariance restoration procedure which involves ambiguities.
Nevertheless, confronting the model with a large data base in several reaction channels is expected to provide a means to overcome this problem.

The parameters in the model have been adjusted [27] to reproduce the Virginia Tech partial wave amplitudes of Arndt et al. [61]. In Ref. [28] we have presented a comparison of our calculated \( S \)-, \( P \)-, and \( D \)-wave amplitudes for pion-nucleon scattering for isospins \( I = 1/2 \) and \( 3/2 \) channels with those of the FA08 single-energy partial wave amplitudes of Ref. [61]. The corresponding results for pion photoproduction and the Compton scattering are given in Ref. [27]. There we noted that both real and imaginary parts of the pion-nucleon scattering amplitudes are described well although some differences start to show up at the upper limit of the energy range considered.

The data for \( p(\gamma, K^+)^\Lambda \) and \( p(\gamma, K^+)\Sigma^0 \) reactions consist of total and differential cross sections and hyperon polarizations measured at CB-ELSA (SAPHIR collaboration [3]) and at JLab (CLAS collaboration [1, 2]) for photon energies ranging from respective thresholds to about 3 GeV. Moreover, beam asymmetry data are available for 9 photon energy beams between 1.5 GeV to 2.4 GeV from SPring8/LEPS [5, 6] group. These data, therefore, cover not only the entire resonance region but also the region where the background contributions are expected to be dominant.

In Fig. 2, we compare the results of our calculations for the total cross sections with the corresponding data of SAPHIR collaboration [3] for \( p(\gamma, K^+)^\Lambda \) and \( p(\gamma, K^+)\Sigma^0 \) reactions. Photon energies \( (E_\gamma) \) range from threshold to about 2.6 GeV. The experimental cross sections

FIG. 2: [color online] Comparison of the calculated total cross sections for the \( p(\gamma, K^+)^\Lambda \) and \( p(\gamma, K^+)\Sigma^0 \) reactions with the corresponding experimental data taken from Ref. [3].
for the $p(\gamma, K^+)\Lambda$ reaction show a steep rise as $E_\gamma$ increases from threshold to about 1.1 GeV. The latter corresponds to a $\gamma p$ channel total invariant mass ($W$) of $\approx 1.7$ GeV which coincides with the masses of $S_{11}(1650)$, $P_{11}(1710)$ and $P_{13}(1720)$ resonances. The decrease in the cross sections just before the threshold for the $K^+\Sigma^0$ channel indicates a cusp due to the opening of this channel which has already been indicated in Refs. [25, 62]. The data in this region are well reproduced by our calculations. There is also a second peak in the data at $E_\gamma \approx 1.5$ GeV ($W \approx 1.9$ GeV). Our calculations describe the data well also in this region.

In contrast to studies reported in Ref. [21, 38, 39, 63], we do not require an additional baryonic resonance $D_{13}(1895)$ in order to explain the data in the second peak region. Looking at the cross sections for the $p(\gamma, K^+)\Sigma^0$ reaction (right panel) one notices that the second maximum in the $p(\gamma, K^+)\Lambda$ data is centered around the same value of $W$ where the only peak is observed in the $K^+\Sigma^0$ channel. Hence, peaks in the $p(\gamma, K^+)\Lambda$ total cross section are more likely to be the consequences of unitarity and multi-channel dynamics. This is further supported by the coupled channel analysis of this reaction as reported in Ref. [26] where the second peak in the $K^+\Lambda$ total cross section data is explained as resulting from the interference between background and resonance contributions and not due to the presence of a $D_{13}(1895)$ resonant state. The same conclusion was arrived also in the previous coupled-channels studies [24].

On the other hand, the total cross sections of the $p(\gamma, K^+)\Sigma^0$ reaction rise smoothly from threshold to its peak at $E_\gamma \approx 1.45$ GeV ($W \approx 1.9$ GeV). The cross sections drop smoothly for $E_\gamma$ larger than this value. Our calculations are able to reproduce the data well in the entire region of photon energies with the exception of some far lower and some higher photon energies where the data are somewhat underestimated.

In Fig. 3, we show the contribution of various resonances and background terms to the total cross sections of $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions as a function of $E_\gamma$. It is clear from this figure that while the background contributions dominate the $p(\gamma, K^+)\Lambda$ cross sections in the entire range of photon energies, they do so only for $E_\gamma > 1.5$ GeV in case of the $p(\gamma, K^+)\Sigma^0$ reaction. It is interesting to note that contributions of $P_{13}(1720)$, $S_{11}(1535)$, $S_{11}(1650)$, $P_{13}(1720)$ and $D_{13}(1520)$ (depicted as P13, S11-1, S11-2, D13-1, respectively in the left panel of Fig. 3) resonances peak at about the same value of $E_\gamma \approx 1.1$ GeV in the $p(\gamma, K^+)\Lambda$ total cross section. In the region around this energy, the resonance contributions are comparable to those of the background terms and they combine together to constitute
FIG. 3: [color online] Partial wave decomposition of the calculated total cross sections for the same reactions as those shown in Fig. 2. Contributions of different resonances are shown by various curves as indicated in the figure. Also shown are the background contributions which consist of Born and $u$- and $t$-channel terms. Experimental data are taken from Ref. [3].

the structure of the first peak in the data. Furthermore, no one resonance individually dominates in this region which is in contrast to the results of Ref. [26]. The contributions of the $P_{11}(1710)$ resonance are very weak and are not included in our study. This is in agreement with the results Ref. [26]. We have also not included a third $S_{11}$ resonance with mass and width around 1.780 GeV and 0.28 GeV, respectively which was considered in descriptions of $p(\gamma, \eta)p$ and $p(\gamma, K^+)^\Lambda$ reactions in Refs. [33, 46].

The peak region in the $p(\gamma, K^+)^\Sigma^0$ total cross section, on the other hand, is dominated by the contributions from the spin-$\frac{3}{2}$, isospin-$\frac{3}{2}$ $P_{33}(1600)$ resonance. Apart from the background and to a lesser extent $D_{33}(1700)$ terms other resonances are almost unimportant in this region. Furthermore, magnitudes of $D_{13}(1700)$, $P_{11}(1440)$ and $P_{11}(1710)$ resonances (depicted as $D_{13}-2$, $P_{11}-1$ and $P_{11}-2$, respectively in the right panel of Fig. 3) are comparatively small in the entire range of photon energies. However, for $E_\gamma$ very close to threshold the $S_{31}(1620)$ resonance is most important.
For both the reactions shown in Fig. 3, we note that the total cross sections beyond 2 GeV are almost solely governed by the contributions of the background terms. In this region all resonance contributions are small and comparable to each other.

Differential cross sections (DCS) provide more valuable information about the reaction mechanism. They reflect the quantum number of the excited state (baryonic resonance) when the cross section is dominated by it. DCS include terms that weigh the interference terms of various components of the amplitude with the outgoing $K^+$ angles. Therefore, the structure of interference terms could highlight the contributions of different resonances in different angular regions. For $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions DCS data of ELSA-SAPHIR group exist for 36 and 35 photon energy bins, respectively in the range of respective thresholds to about 2.60 GeV covering a wide range of $K^+$ center of mass (c.m.) angles. In the left panels of Figs. 4-6 we show comparisons of our calculations for DCS with the corresponding SAPHIR data for the $p(\gamma, K^+)\Lambda$ reaction for energy bins in the range of
FIG. 5: [color online] Same as that shown in Fig. 4 but for photon energies $1.4 \text{ GeV} < E_\gamma < 2.0 \text{ GeV}$ and $1.55 \text{ GeV} < E_\gamma < 2.15 \text{ GeV}$, respectively. The energy bin is indicated in each graph in GeV. The experimental data are taken from Ref. [3].

It is seen that the differential cross sections are flat as a function of kaon angle near the respective thresholds which signifies the dominance of $S$-wave resonances near these energies. As $E_\gamma$ rises further the DCS develop a significant forward peaking which is consistent with the domination of the background terms or the interference between background and $s$-channel resonance contributions. At still higher energies, the data show a tendency of a slow rise at the extreme forward angles.

It is clear that our model describes general trends of the data well in the complete photon energy regime of the SAPHIR measurement. However, a few specific details of the data are missed for some energy bins. In the regions of $1.0–1.20 \text{ GeV}$ and $1.45–1.8 \text{ GeV}$, the angular distributions at the extreme forward angles are not properly reproduced for the $p(\gamma, K^+ )\Lambda$ reaction for photon energy bins in the range of $1.05 \text{ GeV} – 1.55 \text{ GeV}$, $1.55 \text{ GeV} – 2.15 \text{ GeV}$, and $2.15 \text{ GeV} – 2.55 \text{ GeV}$, respectively.
reaction. However, those of the $p(\gamma, K^+)\Lambda$ reaction are well reproduced in these regions.

At photon energies $> 2.0$ GeV, the $p(\gamma, K^+)\Lambda$ cross sections show a tendency of peaking at extreme forward angles while the $p(\gamma, K^+)\Sigma^0$ data do not seem to do so. Within statistical errors our calculations are consistent with this trend of the data, although for the $K^+\Lambda$ channel the agreement is of a lesser quality as compared to that for the $K^+\Sigma^0$ one. In view of the fact that our background terms include both $K$ and $K^*$ exchange diagrams with the same couplings for both the reactions, we have obtained a reasonably good agreement with the data.

There are some discrepancies between the data of ELSA-SAPHIR and CLAS collaborations. The CLAS group has reported consistently larger cross sections at most kaon angles for $E_\gamma > 1.19$ GeV. For certain forward angles and photon energy bins one notices a large difference in the SAPHIR and CLAS data for DCS. Therefore, a simultaneous description of the data of two collaborations has often been problematic for the theoretical models [34, 39]. Our model is no exception to this. We show in Figs. 7 and 8, comparisons between our cal-

FIG. 6: [color online] Same as that shown in Fig. 4 but for photon energies $2.0$ GeV $< E_\gamma < 2.6$ GeV and $2.15$ GeV $< E_\gamma < 2.55$ GeV, respectively. The energy bin is indicated in each graph in GeV. The experimental data are taken from Ref. [3].
FIG. 7: [color online] Comparison of the calculated and experimental differential cross sections from the CLAS collaboration [1] (shown by solid blue squares) for the $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions as a function of the cosine of the $K^+$ c.m. angle for selected bins of photon energy < 1.5. The data of the SAPHIR collaboration (taken from Ref. [3]) at nearby energies are also shown for comparison (by solid black circles).

Calculations and the CLAS data for differential cross sections for $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions for 12 chosen photon energy bins. In these figures the SAPHIR data points are also given for the comparison purpose. Since, the CLAS data are given in energy and angular bins different from those of the SAPHIR one, we have chosen those bins which are nearly equal in two cases.

We note that CLAS and SAPHIR data are identical for $E_\gamma < 1.1$ GeV for both reactions. However, at larger energies considerable difference are seen between the two data sets particularly at forward angles. The CLAS DCS data for the $K^+\Lambda$ channel are more forward peaked for $E_\gamma \approx 1.2 - 1.4$ GeV as compared to the SAPHIR data as well as our calculated cross sections. For the $K^+\Sigma^0$ case, the CLAS DCS are consistently larger than the SAPHIR ones for all angles except for the backward ones for $E_\gamma$ between 1.25 to 1.5 GeV. Our calculations are unable to reproduce this feature.

For $E_\gamma$ between 1.4 -1.7 the $K^+\Lambda$ channel CLAS data have the tendency of backward...
peaking as well along with the stronger forward peaking which is again in contrast to the SAPHIR data as well as our calculations. The backward peaking of the CLAS data disappears for photon energies between 2.0 - 2.6 GeV, however, stronger forward peaking still remains and our calculations are unable to reproduce it fully. For the $p(\gamma, K^+)^0$ reaction the CLAS data show some backward peaking at photon energies between 2.2 - 2.4 GeV. At other energies the differences between the data of the two groups are less noticeable for this channel. Our calculations are in better agreement with the CLAS data for these cases.

Resonance structure in the $s$-channel should appear more clearly in the $W$ dependence of the differential cross sections at various $K^+$ angles. In Fig. 9 (Fig. 10) we show the DCS for $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions as a function of $W$ for positive (negative) values of $\cos(\theta_{K^+})$. The experimental data are from the SAPHIR collaboration. From these figures we note that overall shapes of the $W$ distributions are reproduced well by our calculations for all the angles for both the reactions.

Nevertheless, we also notice that for the case of the $K^+\Lambda$ production our calculations underestimate the data somewhat for $W$ between 1.7-2.0 GeV at forward angles [for $\cos(\theta_{K^+}) = 0.75$, 0.85, and 0.95]. As bulk of the forward peaking is due to $t$-channel exchanges which
are well understood, this leads to the suggestion that a contribution to the background is still missing. It this context supplementing the high energy parts of the $t-$channel exchanges by Regge-trajectory exchange [64–68] may be an interesting option. Work is in progress to include the Regge-trajectory exchange in our model.

For the backward angles (see Fig. 9), the data on the $p(\gamma, K^+)\Lambda$ reaction show two peaks at $W$ around 1.7 GeV and 1.9 GeV. Our calculations are able to reproduce the structure of both the peaks for all the angles except for the most backward one [COS($\theta_{K^+}$) = 0.85] where the peak at $W \approx 1.9$ GeV is underestimated. We would like to stress that unlike Ref. [34], we find no need of including an additional $D_{13}$ resonance (with mass $\approx 1.9$ GeV and width 0.316 GeV) to reproduce the data around $90^0$. The underestimation of the peak for $W$ around 1.9 GeV for COS($\theta_{K^+}$) = 0.85 might be seen as an indication of the need to include such a resonance. However, with the inclusion of this resonance the cross section increases for other backward angles also around this value of $W$ [38] and the signs of the beam asymmetries come out to be opposite to what has been observed experimentally for

FIG. 9: [color online] Comparison of the calculated and experimental differential cross sections for the $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions as a function of the $\gamma p$ invariant mass ($W$) for various positive cosines of the $K^+$ c.m. angle. The experimental data are taken from Ref. [3].
On the other hand, for the $K^+\Sigma^0$ channel, the $W$ dependence of the DCR (see Figs. 9 and 10) is reproduced very well by our calculations for all the angles [corresponding to both negative and positive values of $\cos(\theta_{K^+})$] with the exception of one very forward $\theta_{K^+}$.

Polarization observables provide more sensitive tests of reaction models. The reason for this lies in the fact that these observables are generally very sensitive to the imaginary parts of the amplitudes which are governed by coupling to other channels via the optical theorem. Data on hyperon recoil polarization ($P_Y$, with $Y$ being $\Lambda$ or $\Sigma^0$) have been reported by both SAPHIR and CLAS collaborations [2, 3]. $P_Y$ is related to interferences of the imaginary parts of the resonant amplitudes with real parts of other amplitudes including those of the background terms. In Fig. 11 we compare the results of our calculations $P_Y$ with the corresponding data of the SAPHIR collaboration for $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions. One notices that experimental $P_{\Lambda}$ tend to be positive at backward angles, nearly zero at angles around zero and negative at forward angles. In contrast, $P_{\Sigma^0}$ data show nearly opposite trend. The CLAS $P_Y$ data are used in the analyses of Refs. [34, 38].

Our calculations reproduce approximately the trends seen in the data. The opposite
FIG. 11: [color online] Comparison of our calculations with the experimental data (taken from Ref. [3]) for hyperon polarization for $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions as a function of the cosine of $K^+$ c.m. angle for the photon energy bins (in GeV) as indicated in the figures.

The signs of the observed $P_Y$ of two channels are nearly reproduced. The agreement with data is relatively better for $E_\gamma$ below 1.6 GeV. The large positive back angle polarizations seen in the $P_\Lambda$ data are reproduced for all the photon energy bins. Similarly the large negative experimental $P_{\Sigma^0}$ at these angles are also nearly reproduced. At forward angles our model is relatively less successful in reproducing the $P_\Lambda$ data at $E_\gamma$ above 1.6 GeV. This again indicates perhaps some inadequacy of the background terms within our model.

Beam asymmetry ($\Sigma_B$) is the measure of the azimuthal anisotropy of a reaction yield relative to the linear polarization of the incoming photon. In Fig. 12 we compare the results of our calculations for this observable for both $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions with the corresponding data taken from Ref. [5, 6] which are available for nine energy bins for photon energies between 1.5 GeV to 2.3 GeV. Available experimental $\Sigma_B$ are positive for both the reactions. Our calculations reproduce the data with varying degrees of success. For the $p(\gamma, K^+)\Lambda$ reaction the agreement with the data is relatively better for $E_\gamma < 2.0$ GeV. For larger $E_\gamma$ the data are underestimated by our model. On the other hand, for the $p(\gamma, K^+)\Sigma^0$ case the data are described better for $E_\gamma > 1.9$ GeV while at lower photon energies they are overestimate. In calculations reported in Ref. [26] comparison with the data is shown for
FIG. 12: [color online] Beam asymmetry for the $p(\gamma, K^+)^\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions as a function of the cosine of $K^+$ c.m. angle for 15 photon energies. The experimental data are taken from Ref. [5].

the $K^+\Lambda$ channel for one photon energy ($E_\gamma = 1.946$ GeV) only. In the coupled-channels analysis of Ref. [34], the agreement with the $\Sigma_B$ data for the $p(\gamma, K^+)\Lambda$ reactions is of the same quality as that achieved by us – there too the data are better reproduced for $E_\gamma < 2.0$ GeV while they are underpredicted at energies larger than this. However, we emphasize that such data for both $K^+\Lambda$ and $K^+\Sigma^0$ channels have not been simultaneously analyzed with one parameter set in any other coupled-channels model.

IV. SUMMARY AND CONCLUSIONS

In this paper we investigated the photoproduction reactions $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ within a coupled-channels effective-Lagrangian approach which is based on the $K$-matrix method. Unitarity effects are correctly taken into account, since all important final channels (consisting of two-body systems $\pi N$, $\eta N$, $\phi N$, $\rho N$, $\gamma N$, $K\Lambda$, and $K\Sigma$) are included in the $K$-matrix kernel. We build this kernel by using effective Lagrangians for the Born, $u$-channel, $t$-channel, and spin-$\frac{1}{2}$ and spin-$\frac{3}{2}$ resonance contributions. Thus, the background contributions
are generated consistently and crossing symmetry is obeyed. The advantage of a full coupled-channel calculation is that it allows for the simultaneous calculation of observables for a large multitude of reactions with considerably fewer parameters than would be necessary if each reaction channel is fitted separately. More significantly, the implementation of unitarity ensures that the imaginary parts of the amplitudes are compatible with the cross sections for other channels.

Our model provides reasonable description of the experimental data of the SAPHIR group on total and differential cross sections as well as on hyperon polarizations for photon energies ranging from threshold to up to $\approx 3$ GeV for both $p(\gamma, K^+)\Lambda$ and $p(\gamma, K^+)\Sigma^0$ reactions. The beam asymmetry data of the SPring8/LEPS group for the two reactions are also reasonably reproduced.

An important point about our study is that the same parameter set was used in calculating observables for both the reactions.

We made a detailed investigation of the contribution of various partial waves and showed that peaks seen in the total $p(\gamma, K^+)\Lambda$ cross sections for photon energies around 1.5 GeV (invariant mass of 1.9 GeV) are largely due to coupled-channels effects rather than the contribution of a $D$-wave resonance with mass around 1.9 GeV. A major part of cross sections of this reaction is generated via the background terms and resonances give prominent contributions only in the first peak region (for $E_\gamma$ around 1.1 GeV). On the other hand, the total $p(\gamma, K^+)\Sigma^0$ cross sections are dominated by the $P_{33}$ (1600) resonance in its peak region ($E_\gamma$ around 1.5 GeV).

The agreement between our calculations and the differential cross section data of the CLAS collaboration is not of the same quality as that seen in case of the SAPHIR data, particularly at extreme forward angles. At some backward angles the CLAS data show pronounced peaks for some photon energies but no peak is seen in the corresponding SAPHIR data or in our theoretical cross sections. Whether or not these peaks are an indication for an additional $P$ or $D$ wave resonance is a matter of debate and additional investigations. In this context, it is quite desirable to settle the issue of mutual inconsistency between the CLAS and SAPHIR data sets.

Our work shows that it is indeed possible to fit meson photoproduction data of many channels simultaneously with a single parameter set within a coupled-channels model. Further improvement of our model is however, necessary for a better description of the data at
extreme forward angles in case of higher photon energies.

Appendix A: Effective Lagrangians

We list here the effective Lagrangians for various vertices. $p$, $k$, $p'$ and $-q$ represent four momenta of the initial nucleon, final meson, final nucleon and photon, respectively. We assume that meson momenta are directed into the vertex, so that energy momentum conservation reads as $p + k = p' - q$.

For the nucleon vertices the following couplings were used

\begin{equation}
\begin{split}
L_{NN\pi} &= ig_{NN\pi} \bar{\Psi}_N \left( \chi \varphi_\pi + \frac{i \not\! D \varphi_\pi / 2m_N}{\chi + 1} \right) \gamma_5 \Psi_N \\
L_{NN\eta} &= ig_{NN\eta} \bar{\Psi}_N \left( \chi \varphi_\eta + \frac{i \not\! D \varphi_\eta / 2m_N}{\chi + 1} \right) \gamma_5 \Psi_N \\
L_{NN\sigma} &= -g_{NN\sigma} \bar{\Psi}_N \varphi_{\sigma} \Psi_N \\
L_{NN\rho} &= -g_{NN\rho} \bar{\Psi}_N \left( \gamma_\mu \varphi_{\rho}^\mu + \frac{\kappa_\rho}{2m_N} \sigma_{\mu\nu} \partial^\nu \varphi_{\rho}^\mu \right) \cdot \tau \Psi_N \\
L_{NN\omega} &= -g_{NN\omega} \bar{\Psi}_N \left( \gamma_\mu \varphi_{\omega}^\mu + \frac{\kappa_\omega}{2m_N} \sigma_{\mu\nu} \partial^\nu \varphi_{\omega}^\mu \right) \Psi_N \\
L_{NN\phi} &= -g_{NN\phi} \bar{\Psi}_N \left( \gamma_\mu \varphi_{\phi}^\mu + \frac{\kappa_\phi}{2m_N} \sigma_{\mu\nu} \partial^\nu \varphi_{\phi}^\mu \right) \Psi_N \\
L_{NN\gamma} &= -e \bar{\Psi}_N \left( \frac{1 + \tau_0}{2} \gamma_\mu A^\mu + \frac{\kappa_\tau}{2m_N} \sigma_{\mu\nu} \partial^\nu A^\mu \right) \Psi_N \\
L_{NN\gamma\varphi} &= -e \frac{g_{NN\gamma\varphi}}{2m_N} \bar{\Psi}_N \gamma_5 \gamma_\mu \left[ \tau \times \varphi \right] A^\mu .
\end{split}
\end{equation}

The parameter $\chi$ controls the admixture of pseudoscalar and pseudovector components in the corresponding Lagrangian. Its value is taken to be 0.5. This value was obtained in our previous study of photoproduction of associated strangeness [25] and has been held fixed in the study of all other reactions within our model. Nucleon spinors are depicted by $\Psi$ and meson fields by $\varphi$. The magnetic moments are represented by $\kappa$. $L_{NN\gamma\varphi}$ generates the seagull or the contact term diagrams. We have followed the notations of Ref. [69].
The Lagrangians for the meson vertices are

\[
\mathcal{L}_{\rho\pi\pi} = -g_{\rho\pi\pi}\varphi_{\rho\mu} \cdot \left(\varphi_\pi \times \partial^\mu \varphi_\pi\right)/2
\]

\[
\mathcal{L}_{\gamma\pi\pi} = e\varepsilon_{3ij}A_\mu(\varphi_\pi, \partial^\mu \varphi_\pi)
\]

\[
\mathcal{L}_{\mu\gamma\pi} = \frac{g_{\mu\gamma\pi}}{m_\pi}(\varepsilon_{\mu\nu\rho\sigma}(\partial^\rho A^\mu)(\partial^\sigma \varphi_\nu))
\]

\[
\mathcal{L}_{\omega\gamma\pi} = \frac{g_{\omega\gamma\pi}}{m_\pi}(\varepsilon_{\mu\nu\rho\sigma}(\partial^\rho A^\mu)(\partial^\sigma \omega_\nu))
\]

\[
\mathcal{L}_{\phi\gamma\pi} = \frac{g_{\phi\gamma\pi}}{m_\pi}(\varepsilon_{\mu\nu\rho\sigma}(\partial^\rho A^\mu)(\partial^\sigma \phi_\nu))
\]

\[
\mathcal{L}_{\phi\gamma\eta} = \frac{g_{\phi\gamma\eta}}{m_\pi}(\varepsilon_{\mu\nu\rho\sigma}(\partial^\rho A^\mu)(\partial^\sigma \phi_\nu))
\]

\[
\mathcal{L}_{\rho\rho\gamma} = 2e\left(A^\mu(\partial_\mu \varphi_\rho)\tau_0 \varphi_\rho \cdot \partial^\nu \varphi_\rho + (\partial^\nu A^\mu)\varphi_\rho_0 \tau_0 \varphi_\rho_\mu\right)
\]

\[
\mathcal{L}_{\phi\kk} = -ig_{\phi\kk}(\varphi_\kk, \partial^\mu \varphi_\kk)\phi_\mu
\]

\[
\mathcal{L}_{\eta\kk^*} = -ig_{\eta\kk^*}(\varphi_\kk^*, \partial^\mu \varphi_\kk)\phi_\mu
\]

\[
\mathcal{L}_{\pi\kk^*} = -ig_{\pi\kk^*}(\varphi_\kk^*, \partial^\mu \varphi_\kk)\varphi_\mu
\]

\[
\mathcal{L}_{\rho\gamma\pi} = 2e\left(A^\mu(\partial_\mu \varphi_\rho)\tau_0 \varphi_\rho \cdot \partial^\nu \varphi_\rho + (\partial^\nu A^\mu)\varphi_\rho_0 \tau_0 \varphi_\rho_\mu\right)
\]

\[
\mathcal{L}_{\kk^*\kk} = g_{\kk^*\kk}(\varphi_\kk^*, \partial^\mu \varphi_\kk)\varphi_\mu
\]

\[
\mathcal{L}_{\kk^*\kk^0} = \frac{g_{\kk^*\kk^0}}{m_\pi}(\varepsilon_{\mu\nu\rho\sigma}(\partial^\rho A^\mu)(\partial^\sigma \varphi_\kk^0))
\]

\[
\mathcal{L}_{\kk^*\kk^±} = \frac{g_{\kk^*\kk^±}}{m_\pi}(\varepsilon_{\mu\nu\rho\sigma}(\partial^\rho A^\mu)(\partial^\sigma \varphi_\kk^±))
\]

The coupling constants entering into Eqs. (A.1) and (A.2) together with baryon magnetic moments are listed in Table III. We have taken positive values for all primary coupling constants involving the nucleon. In particular, the sign of \(g_{NK\Lambda}\) differs from its customary negative value \[70\] However, we would like to stress that in a calculation like ours and also in many of those cited in Ref. \[70\] this sign is undetermined. Changing the sign of all the coupling constants involving a single \(\Lambda\)-field leaves the calculated observables invariant since it corresponds to a sign redefinition of this field. The magnitudes of the couplings are within the broad range specified in \[70\].

For the \(S_{11}, S_{31}, P_{11}\) and \(P_{3,1}\) resonances the hadronic couplings are written as

\[
\mathcal{L}_{\varphi NR_{1/2}} = -g_{\varphi NR}\bar{\Psi}_R\left[\chi_i \Gamma_\varphi + (1 - \chi) \frac{1}{M} \Gamma_{\mu}(\partial^\mu \varphi)\right]\Psi_N + \text{H.c.}, \quad (A3)
\]
| Parameter | Value | Parameter | Value |

where $M = (m_R\pm m_N)$, with upper sign for even parity and lower sign for odd parity resonance. The operator $\Gamma$ is $\gamma_5$ and unity for even and odd parity resonances, respectively. For isovector mesons, $\varphi$ in Eq. (A.3) needs to be replaced by $\tau \cdot \varphi$ for isospin-1/2 resonances and by $\mathbf{T} \cdot \varphi$ otherwise.

The corresponding electromagnetic couplings are

$$\mathcal{L}_{\gamma NR_{1/2}} = -eg_1\bar{\Psi}_R \frac{\Gamma}{4m_N} \sigma_{\mu\nu} \Psi_N F^{\mu\nu} + H.c.,$$

where $\Psi_R$ is the resonance spinor and $F^{\mu\nu} = \partial^\mu A^\nu - \partial^\nu A^\mu$. The operator $\Gamma$ is 1 for the positive parity resonance and $-i\gamma_5$ for the negative parity one.

For spin-3/2 resonances, we have used the gauge-invariant effective Lagrangians as discussed in Refs. [50, 57, 58, 71, 72]. We write here the vertex functions used by us in computation...
involving these vertices. The resonance-nucleon-pion vertex function (e.g.) is given by

\[ \Gamma_{R_{3/2} \rightarrow N\pi}^\alpha = \frac{g_1}{m_\pi} \left[ \gamma^\alpha (q \cdot p) - \hat{q}q^\alpha \right] \left[ (1 - \chi) + \chi \hat{p}/M_p \right], \]  

(A5)

and the corresponding electromagnetic vertices are

\[ \Gamma_{R_{3/2} \rightarrow N\gamma}^{\alpha\mu} = \left\{ \left[ (g_2 + 2g_1) \left[ q^\alpha p^\mu - g^{\alpha\mu} p \cdot q \right] + \right. \right. \]
\[ \left. \left. g_1 \left[ g^{\alpha\mu} \hat{q}q^\mu - q^{\alpha\mu} \hat{p} \gamma^\mu + \gamma^\alpha (\gamma^\mu p \cdot q - \hat{p}^\mu \hat{q}) \right] + \right. \right. \]
\[ \left. \left. g_3 \left[ \left( -q^2 g^{\alpha\mu} + q^\mu q^\alpha \right) \hat{p} + \left( q^2 p^\mu - q^\mu p \cdot q \right) \gamma^\alpha \right] \right\} \times \gamma_5 \left[ (1 - \chi) + \chi \hat{p}/M_p \right]. \]  

(A6)

Here \( p \) is the four-momentum of the resonance and \( q \) is that of the meson. Index \( \alpha \) belongs to the spin-\( \frac{3}{2} \) spinor and \( \mu \) to photon. Interesting property of these vertices is that the product, \( p \cdot \Gamma = 0 \), where \( \Gamma \) defines the vertices on the left hand side of Eqs. (A.5) and (A.6). As a consequence, the spin-\( \frac{1}{2} \) part of the corresponding propagator becomes redundant as its every term is proportional to either \( p_\mu \) or \( p_\nu \). Thus only spin-\( \frac{3}{2} \) part of this propagator gives rise to non-vanishing matrix elements.
