Abstract—Cotton plant is one of the most widely cultivated crop across worldwide. The leaf is one of the important parts which help in the food production. There are different cotton leaf diseases like Alternaria spot, foliar, bacterial blight, etc. which affects the agricultural yield. In order to detect the diseases, leaf region extraction becomes a significant task and to achieve this we use image processing techniques. Henceforth in this paper, a novel method used to extract the leaf region from a complex background. The proposed method is used for leaf extraction from complex background. The algorithm used in this method is modified factorization based active contour (MFACM) which helps in getting better output images. The database images used for research are acquired from the field using a digital camera. The proposed work is compared with existing active contour algorithms like Gradient Vector Flow (GVF), Adaptive Diffusion Flow (ADF), and Vector Flow Convolution (VFC). From the experiment, it can be observed that the proposed method is better than the other active contour methods in terms of computation time and the number of iterations. In addition to that segmented result is analyzed using specificity, sensitivity, precision which showed that our proposed method is better than the other methods.

Keywords—Cotton leaf; active contour; Gradient Vector Flow (GVF); Adaptive Diffusion Flow (ADF); Vector Flow Convolution (VFC); Modified factorization based active contour (MFACM)

I. INTRODUCTION

Plants play an important source of food for human beings. If plants get affected than yield will also get affected. Therefore, many researchers are into this field of plant phenotyping [7] and there has been extensive research in this area. Plant phenotyping is a research area where the quantitative measurements of the structural and functional properties are performed. The experiment is carried out using some of the computer vision methods like analyzing the image through software. Because of this there has been research in this field for plant disease classification, leaf counting, observing the development and growth of the plant. In literature, there are many researchers who did lot of work for segmenting the leaf images [15,25,26,27] for example leaf segmentation without background and with complex background, automatic identification of plant species. In some cases, segmentation is performed using edge based and local based method also is used [16].

Kiruba raij [2], proposed a method for the herbal leaves segmentation from the complex background. In this chan-vase method is used for the segmentation of leaf or leaves from background when compared to other techniques like k means clustering, local adaptive mean color, without affecting the color, textures. J Praveen kumar [3], introduced the new edge enhancement technique and graph-based method to extract the leaf region. Later it involves counting the number of leaves using circular Hough transform. Manual Grand et al. [4], a review of comparative study of 13 different segmentation methods. The Guided active contour approach was one among them and it has good segmentation results. Jones De Kylder [6], proposed a new active contour framework for segmentation. In this, the author proposed that whenever at the edge of the object contour is placed at that moment it will maximize probability. The internal and external probability distribution functions are learned from a ground truth training set. So, using this segmentation is performed and it gave an outstanding result. Shivalka Sharma [7], presented the review of various methods available for leaf segmentation. Xiaodong Tang [10], introduced leaf extraction from a complicated background using marker-controlled watershed algorithm for image of the individual channel gradient image of Hue, Saturation and Intensity separately. The applying of the watershed algorithm leads to the segmentation of the leaf region and author used solidity measures, to know how the performance of the method is.

Though there are various techniques used for the leaf segmentation [11,12,17,28] but with complex background very less research is carried out. Taking this into consideration, we proposed a leaf segmentation from complex background using modified factorization based active contour for texture segmentation. The structure of the paper is as follows: Section II is Literature survey; discussed about previous work done; Section III is Methodology: explains regarding proposed method; Section IV is Results and discussion: the comparative study results; and Section V presents Conclusion.

II. LITERATURE SURVEY

In this, we will be focusing on the previous work done by researchers in active contours, or snakes. Active contour are curves which are generated by the computer. The curve will move towards the edges of an object based on the image energies. There are various applications of active contours like in the medical field like to outline tumor in the brain or it may be for the number recognition etc. But it has some disadvantages too like if the object boundary is too far than its difficult of the curve to evolve towards the object boundaries.
Active contours which there are two kinds, namely parametric
and geometric.

1) The parametric deformable model – curves which are moved
under the influence of internal and external forces
[19,22].

2) Geometric deformable model – level set function is
used to represent curves and surfaces implicitly in higher-
dimensional scalar function [18,20,21].

There are various applications of these models in wide
range of medical field [24]. But apart from that its
contribution is in leaf segmentation also. And in this paper,
both methods are taken into consideration for experiment.

A. Gradient Vector Flow

Xu and Prince [5], introduced a gradient vector flow
method to overcome the problems of traditional snake. The
traditional snake had a problem with the convergence towards
the concave region and also with the limited capture range. So,
in this author introduced a new external force which helps the
snake to move towards the concave regions.

The equation for the traditional snake is given by

\[ E_{\text{int}} = \int_0^1 E_{\text{snake}}(v(s)) \, ds \]

\[ = \int_0^1 E_{\text{int}}(v(s)) + E_{\text{ext}}(v(s)) \quad (1) \]

Where \( E_{\text{int}} \) and \( E_{\text{ext}} \) are the internal and external energies.
\( E_{\text{ext}} \) is calculated from the image. In this author proposed a new
external force which is given by.

\[ E_{\text{ext}}(v(s)) = -|\nabla [G_\sigma(x,y) * I(x,y)]|^2 \quad (2) \]

Where \( G_\sigma(x,y) \) is a two dimensional Gaussian function
with standard deviation \( \sigma \) and \( V \) is the gradient operator. This
energy helps in moving the snake towards the edges.

It will give better performance with respect to deep
concavities of an image.

B. Adaptive Diffusion Flow

Yuwei Wu [8], proposed a method of adaptive diffusion flow
which is the modified version of gradient vector flow. Gradient
vector flow has advantages with respect to reaching deep
concavities but it had a problem with the leakage of weak edges
and narrow concavity. So, to improve the author
replaced the smoothness energy term of GVF to harmonic
hyper surface minimal functional and to achieve the contour to
the deep and narrow concavities the infinite laplacian
functional is incorporated.

Following are the equations for the adaptive diffusion flow
which helps in overcoming the problems of GVF.

Case i): To preserve the weak edges following is the
harmonic hypersurface functional defined as.

\[ E(v) = \iint \frac{1}{|\nabla v|} \cdot \left( \sqrt{1 + |G_\sigma \nabla v|^2} \right)^{p(|\nabla v|)} \quad (3) \]

Where \( f \) is the edge of the image \( I \), \( p(\cdot) \) is a decreasing
monotonously function which ranges from 1 to 2. And
\( p(|\nabla f|) = 1 + \frac{1}{1 + |G_\sigma \nabla f|} \) such that when \( |G_\sigma \nabla f| \rightarrow 0 \), \( p(\cdot) \)
\rightarrow 2, this function behaves like isotropic diffusion within
homogeneous regions. When \( |G_\sigma \nabla f| \rightarrow \infty \), \( p(\cdot) \rightarrow 1 \) behaves
like total variation model. This basically helps in preserving
the weak edges of an image.

Case ii): The laplacian energy functional helps in contour
convergence of narrow and deep concavities of an image.

Following is the laplacian energy functional.

\[ E_{\text{lap}} = \iint |V_\sigma \nabla v| \, dx \, dy \quad (4) \]

So, using both the cases the adaptive diffusion method is
given by.

\[ E(u) = \iint \left[ g \cdot (|V_\sigma \nabla u|) + (1 - m) \cdot \frac{1}{p(|\nabla f|)} \cdot \left( \sqrt{1 + |G_\sigma \nabla u|^2} \right)^{p(|\nabla f|)} + h \cdot (|u - f|^2) \right] \, dx \, dy \quad (5) \]

Where \( g, h, m \) are the weighting functions.

C.Vector Flow Convolutions

Bing Li [9], introduced new external force called as vector
field convolution (VFC). Here the external force vector field
kernel \( k(x,y) \) in which all the vectors point to the kernel
origin.

\[ k(x,y) = m(x,y)n(x,y) \]

The convolution of kernel \( k(x,y) \) with edge map \( f(x,y) \)
which is generated from the image \( I(x,y) \) which is considered
as VFC external force.

\[ \text{vfc} = f(x,y) * k(x,y) \]

Here edges are more prominent compare to homogeneous
regions. The VFC will result in edge map which doesn’t
depend on the origin of the vector field kernel but it depends
on the magnitude of the vector field kernel \( m(x,y) \). Author
proposed a two magnitude functions given by.

\[ m_1(x,y) = (r + \varepsilon)^{-\gamma} \quad (6) \]

\[ m_2(x,y) = \exp\left(\frac{-r^2}{\varsigma}\right) \quad (7) \]

Where \( \gamma \) and \( \varsigma \) are positive parameters to control the
decrease of vector field, \( \varepsilon \) is a positive constant to prevent
division by zero at the origin. \( m_1(x,y) \) which influence the FOI
as increases as \( \gamma \) decreases. \( m_2(x,y) \) is a Gaussian shape
function and \( \varsigma \) represents the standard deviation.

D. Level Set Method

Stanley Osher [29], introduced the level set method
formulation for the evolution of the curve. The curve is
represented implicitly as a level set of a scalar function
referred as level set function which is defined as the set of
points that have same function value. Fig. 1 shows the curve
at zero level set of a function, \( \Phi(x) = 0 \).

E. Drawbacks

One of the drawbacks, reinitialization of the curve won’t
be possible whenever the level set function is far away from a
signed distance. Practically whenever the time step is not
selected small enough at that time evolving level set function
can depart greatly from its value as signed distance in a small number of iteration steps.

![Curve at Zero Level Set.](image1.png)

Fig. 1. Curve at Zero Level Set.

To maintain curve evolution stability and guaranteeing required results re-initialization has been broadly used as a numerical remedy. Later, various authors came with different methods which helped in overcoming the cost of re-initialization of curve during evolution.

Chumming Li [23], came with level set evolution without reinitialization cost which can be achieved by forcing the level set function to be close to signed distance function. The internal energy is used for deviation of the level set function from a signed distance function and external energy based on the desired feature like object boundary are used for the motion of zero level set curve.

III. METHODOLOGY

A. Leaf Database

There are nearly 500 images for database. The images are captured under suitable conditions using Nikon digital camera of size 6000×4000. The images are resized nearly to 256 x 256 so that processing of images is faster. Fig. 2 shows the sample leaf images.

There are two different types of deformable models parametric and geometric. ADF, VFC, GVF are the methods for leaf segmentation and modified factorization based active contour.

B. Proposed Method

The proposed method is based on factorization-based active contour for texture segmentation [11][14] with modification. In geometric deformable the distance regularized active contour is used for the implementation [13]. The method is modified version of a factorization based active contour model for texture segmentation [11]. So, the process of extracting the leaf region shown in Fig. 3.

C. Modified Factorization based Active Contour Method (MFACM)

The images which are captured will undergo into preprocessing stage of flattening the field correction and using Gaussian pyramid.

![Sample Leaf Images.](image2.png)

Fig. 2. Sample Leaf Images.

![Process of Extracting the Leaf Region.](image3.png)

Fig. 3. Process of Extracting the Leaf Region.

The Gaussian pyramid is a technique in image processing that breaks down an image into successively smaller groups of pixels, in repeated steps, for the purpose of blurring it. This is performed so that it is easier to detect the edges of an object.

The proposed method uses level set method introduced by chumming li [13], distance regularization is given by

\[ E_{\text{regularization}}(\phi) = \int_{\Omega} \frac{1}{2} (|\nabla \phi(x) - \mathbf{1}|^2) dx \]  

(7)

Where \( \nabla \phi \) denote the derivative of the level set method. The energy functional proposed by the author is defined as

\[ E(\phi, R) = \mu E_{\text{data}}(\phi, R) + \nu E_{\text{regularization}}(\phi) \]  

(8)

where \( \mu \) and \( \nu \) are two positive constant which helps in balancing the total energy with respect to the corresponding terms in the equation. The equation is based on gradient based method.

The evolution process is defined as follows

\[ \frac{\partial \phi}{\partial t} = - \frac{\delta E(\phi, R)}{\delta \phi} = -\delta_x(\phi)\mu (w_o - w_b) + \nu (\nabla^2 \phi - \text{div}(\frac{\nabla \phi}{|\nabla \phi|})) \]  

(9)

Where \( w_o \) and \( w_b \) are N dimension vectors.

Apart from level set method the proposed uses factorization-based texture segmentation introduced by Yaun et al. In this, spectral histograms are considered as texture features and a MxN matrix is calculated representing the feature matrix consisting of local window centered at each pixel. The matrix is denoted by \( Y \) which is given as.
Y = Rβ + ε

Where R is an MxL matrix gives you the columns which represent the features for the region to be segmented. β is the columns representing the weight vectors for every region and ε is the additive noise.

The data energy can be represented as

\[ E_{data}(ϕ, R) = -\int_{Ω} (H_{ε}(ϕ)w_b(x, R) + (1 - H_{ε}(ϕ))w_0(x, R))dx \]  

(9)

From the above equation 9 it can be observed that when the curve reaches the object boundary it data term will have minimum value at that point.

In this proposed method, we have included Gaussian pyramid along with factorization based active contour method.

Algorithm

Step 1: Read the original image.
Step 2: RGB to Gray scale image.
Step 3: Histogram of RGB is matched with its gray scale image.
Step 4: Flat field correction with sigma =1.
Step 5: Gaussian low pass filter with hzise = [5 5] and sigma = 10.
Step 6: Subtracting ‘q’ image from blurred image.
Step 7: Reducing the flat filed corrected image using Gaussian pyramid.
Step 8: Expanding the reduced image IR.
Step 9: Fuse expanded image ‘IR’ and flat flied correction image ‘O’.
Step 10: Fuse Q and subtracted image q.
Step 11: Flat field correction is applied to Q.
Step 12: Image intensity values are adjusted with gamma = 0.01.
Step 13: Flat field correction is applied with sigma = 5.
Step 14: Required region should be selected from the original image.
Step 15: Segmentation is performed using modified factorization active contour method.
Step 16: Segmentation output.

IV. RESULTS AND QUANTITATIVE COMPARISONS

The images with complex background are captured from a various agriculture field of cotton plant leaf images. The images are captured from a digital camera of size 6000x4000.

The images were preprocessed using flat field correction and used Gaussian pyramid for the better visibility of the edges of the images. Later the processed image will be used for factorization based active contour. The results obtained using modified factorization based active contour will give better results when compare to other results.

The proposed method and parametric deformable model methods Gradient Vector Flow (GVF), Adaptive Diffusion Flow (ADF), Vector Field Convolution (VFC) are experimented with dataset created by Nikon digital camera of image resolution 6000x4000. In this paper, Modified Factorization based Active Contour Method (MFACM) is compared with the existing parametric deformable models.

Fig. 4 and 5 shows the results obtained after applying the modified F ACM, GVF, ADF and V FC methods along with ground truth image. The performance of the methods are analyzed using time computation and segmentation measures like precision, accuracy, sensitivity, specificity. Table I gives the details regarding the time computation obtained from the various methods and we can observe that our proposed method takes less time when compare to other.

Fig. 6 shows the graph of time taken versus the number of iterations. Table II displays the output of different segmentation performance measures using ground truth images. From the table it can be seen that accuracy, precision, sensitivity, etc. are more compare to methods of parametric deformable models and it’s been represented in the graph shown in Fig. 7.
TABLE I. TIME SPENT FOR GVF, VFC, ADF AND MFACM

| Time spent | GVF | VFC | ADF | MFACM |
|------------|-----|-----|-----|-------|
| Iterations | 60  | 60  | 60  | 60    |
| Leaf       | 24.68 | 29.14 | 29.41 | 12.8  |
| leaf1      | 23.73 | 40.67 | 32.54 | 11.06 |
| leaf2      | 22.43 | 41.71 | 27.1  | 9.26  |
| leaf3      | 23.63 | 37.01 | 30.91 | 11.59 |
| leaf4      | 17.96 | 36.23 | 17.35 | 12.74 |
| leaf5      | 21.68 | 29.32 | 22.92 | 11.54 |

Fig. 5. (a) Input Image (b) Modified FACM Output (c) GVF Output (d) ADF Output (e) VFC Output (f) Ground Truth Image.

Fig. 6. Graph for Time Taken Versus Number of Iteration.

Fig. 7. Graph for Precision, Accuracy, Sensitivity, Specificity with Respect to MAFCM, ADF, VFC, GVF.

V. CONCLUSION

Leaf segmentation from complex background is performed using modified factorization based active contour for cotton leaf images. The segmented results are better than when compared to the parametric active contour methods. In this, active contour methods like GVF, VFC and ADF and level set method modified factorization based active contour method. From the results, we can observe that modified factorization based active contour method is good when compared to other methods in terms of time taken to perform segmentation. The precision, recall, sensitivity, etc. are calculated and the values are good when related to other methods. So, from this we can conclude that modified FACM is better than the other geometric and parametric active contour method.
