A NOTE ON SIGN CONVENTIONS IN LINK FLOER HOMOLOGY

SUCHARIT SARKAR

Abstract. For knots in $S^3$, the bi-graded hat version of knot Floer homology is defined over $\mathbb{Z}$; however, for an $l$-component link $L$ in $S^3$ with $l > 1$, there are $2^{l-1}$ bi-graded hat versions of link Floer homology defined over $\mathbb{Z}$; the multi-graded hat version of link Floer homology, defined from holomorphic considerations, is only defined over $\mathbb{F}_2$, and there is a multi-graded version of link Floer homology defined over $\mathbb{Z}$ using grid diagrams. In this short note, we try to address this issue, by extending the $\mathbb{F}_2$-valued multi-graded link Floer homology theory to $2^{l-1}$ $\mathbb{Z}$-valued theories. A grid diagram representing a link gives rise to a chain complex over $\mathbb{F}_2$, whose homology is related to the multi-graded hat version of link Floer homology of that link over $\mathbb{F}_2$. A sign refinement of the chain complex exists, and for knots, we establish that the sign refinement does indeed correspond to the sign assignment for the hat version of the knot Floer homology. For links, we create $2^{l-1}$ sign assignments on the grid diagrams, and show that they are related to the $2^{l-1}$ multi-graded hat versions of link Floer homology over $\mathbb{Z}$, and one of them corresponds to the existing sign refinement of the grid chain complex.

1. Introduction

Knot Floer homology, primarily as an invariant for knots and links inside $S^3$, was discovered by Peter Ozsváth and Zoltán Szabó [8], and independently by Jacob Rasmussen [15]. Later, a related invariant for links, called link Floer homology, was constructed by Peter Ozsváth and Zoltán Szabó [12]. However, due to certain orientation issues, the link invariant was only constructed over $\mathbb{F}_2$, instead of $\mathbb{Z}$. This short note is the author’s effort to understand the orientation issues that are known, and to resolve some of the issues that are unknown.

Let us describe the algebraic structure of knot Floer homology in the simplest case, as described in [8]. Let $K$ be a null-homologous knot in $\#^{l-1}(S^1 \times S^2)$. Then there are $2^{l-1}$ bi-graded chain complexes over $\mathbb{Z}$, such that they all give rise to the same complex when tensored with $\mathbb{F}_2$. The two gradings are called the Maslov grading $M$ and the Alexander grading $A$. The boundary maps preserve the Alexander grading, but lower the Maslov grading by one. Therefore, the Maslov grading acts as the homological grading while the Alexander grading acts as an extra filtration. The homology of the chain complexes is called the hat version of the knot Floer homology. Therefore, we get an $\mathbb{F}_2$-valued bi-graded hat version of knot Floer homology and $2^{l-1}$ $\mathbb{Z}$-valued bi-graded hat versions of knot Floer homology.

are link invariants, and on condensing the
\( HFK \) definition from [12] the link Floer homology, and denoted it by
\( \widehat{CFK} \). We plan to address more subtle. In particular, we will encounter boundary degenerat ions, and we will however, the holomorphic considerations and the orientation issue s are significantly
A similar story (except possibly the last bit of coincidence) holds for t he other
\( HFL \) definition of link Floer homology is given. Given a link \( L \subset S^3 \), with \( l \) components, and after making certain auxiliary choices, we get \( 2^{l-1} \) bi-graded chain complexes over \( \mathbb{Z} \), henceforth denoted by \( \widehat{CFK} (L, \mathbb{Z}, o) \), where \( o \), called an orientation system, takes values in an indexing set of \( 2^{l-1} \) elements, and records which of the \( 2^{l-1} \) chain complexes is the one under consideration. All of the \( 2^{l-1} \) chain complexes give rise the same bi-graded chain complex over \( \mathbb{F}_2 \), \( \widehat{CFK} (L, \mathbb{F}_2) = \widehat{CFK} (L, \mathbb{Z}, o) \otimes \mathbb{F}_2 \). The reader should be warned that these bi-graded chain complexes, \( \widehat{CFK} (L, \mathbb{Z}, o) \) and \( \widehat{CFK} (L, \mathbb{Z}) \), are not link-invariants (they might depend on the auxiliary choices that we did not specify, but simply alluded to), but their homologies are link invariants. Therefore, we get one \( \mathbb{F}_2 \)-valued bi-graded hat version of knot Floer homology \( \widehat{HFK} (L, \mathbb{F}_2) = H_* (\widehat{CFK} (L, \mathbb{F}_2)) \), and \( 2^{l-1} \mathbb{Z} \)-valued bi-graded hat versions of knot Floer homology \( \widehat{HFK} (L, \mathbb{Z}, o) = H_* (\widehat{CFK} (L, \mathbb{Z}, o)) \). We often let \( \widehat{HFK} (L, \mathbb{Z}) \) denote any one of the \( 2^{l-1} \) versions, or a canonical one, namely the one coming from the canonical choice of orientation systems in [9]. However, to decide which of the \( 2^{l-1} \) groups \( \widehat{HFK} (L, \mathbb{Z}, o) \) is the canonical one, one needs to understand some of the other versions of link Floer homology, most notably the infinity version. This seems to be a harder problem, for reasons that we will discuss shortly.

In [12], the story for links is treated in a slightly different light, and a new definition of link Floer homology is given. Given a link \( L \) with \( l \) components in \( S^3 \), modulo certain choices, a chain complex \( CFL (L, \mathbb{F}_2) \) over \( \mathbb{F}_2 \) is constructed. The chain complex carries \( (l+1) \) gradings: a singleMaslov grading \( M \), which is lowered by one by the boundary map, and \( l \) Alexander gradings \( A_1 , A_2 , \ldots , A_l \), one for each link component, each of which is preserved by the boundary map. The homology of the chain complex \( HF\mathbf{L} (L, \mathbb{F}_2) = H_* (CFL (L, \mathbb{F}_2)) \) is an \( \mathbb{F}_2 \)-valued \( (l+1) \)-graded homology theory; called the link Floer homology, and it is a link invariant. These two definitions, \textit{a priori}, are different. Therefore, we have been careful throughout; we have called the definition from [8] the knot Floer homology (even when talking about links), and denoted it by \( \widehat{HFK} \), and we have called the definition from [12] the link Floer homology, and denoted it by \( HF\mathbf{L} \). However, by a miraculous coincidence, it turns out that if we condense the \( l \) Alexander gradings in \( HF\mathbf{L} (L, \mathbb{F}_2) \) into one single Alexander grading \( A = \sum_i A_i \), then the resulting \( \mathbb{F}_2 \)-valued bi-graded homology group is isomorphic to \( \widehat{HFK} (L, \mathbb{F}_2) \).

In this note, we will complete the picture by constructing \( 2^{l-1} \mathbb{Z} \)-valued chain complexes, \( CFL (L, \mathbb{Z}, o) \), each carrying a Maslov grading \( M \), and \( l \) Alexander gradings \( A_1 , A_2 , \ldots , A_l \), such that the homologies \( HF\mathbf{L} (L, \mathbb{Z}, o) = H_* (CFL (L, \mathbb{Z}, o)) \) are link invariants, and on condensing the \( l \) Alexander gradings into one Alexander grading \( A = \sum_i A_i \), we get the \( 2^{l-1} \mathbb{Z} \)-valued bi-graded homology groups \( \widehat{HFK} (L, \mathbb{Z}, o) \).

A similar story (except possibly the last bit of coincidence) holds for the other versions of link Floer homologies, most notably the minus, plus and infinity versions; however, the holomorphic considerations and the orientation issues are significantly more subtle. In particular, we will encounter boundary degenerations, and we will have to orient the relevant moduli spaces in a consistent fashion. We plan to address
that again, it is an interesting question whether indeed, we construct a bijection between the set of link modules,\( \hat{\text{HFL}}(L, \mathbb{Z}) \times \mathbb{F}_2 \otimes \mathbb{F}_2 \), where, in the \( \mathbb{F}_2 \) tensor with itself \( m_i - 1 \) times, for one of the generators, all the \( (l+1) \) gradings are zero, and for the other generator, the Maslov grading \( M = -1 \), and the Alexander grading \( A_j = -\delta_{ij} \).

Very shortly thereafter, [4] assigned signs of \( \pm 1 \) to each of the boundary maps in the chain complex \( C(G) \) in a well defined way, such that it remains a chain complex and its homology (over \( \mathbb{Z} \)) is isomorphic to \( \hat{\text{HFG}}(L, \mathbb{Z}) \otimes \sigma (\otimes m_i^{-1}(\mathbb{F}_2 \oplus \mathbb{Z})) \), for some \( (l+1) \)-graded group \( \hat{\text{HFG}}(L, \mathbb{Z}) \), which is a link invariant. A very natural question that arises is whether the new homology group \( \hat{\text{HFL}}(L, \mathbb{Z}) \) is isomorphic to \( \hat{\text{HFL}}(L, \mathbb{Z}, \sigma) \) for some \( \sigma \). We establish that the answer is in the affirmative, and indeed, we construct \( 2^{l-1} - 1 \) other sign assignments on the boundary maps of \( C(G) \), such that the homologies of these \( 2^{l-1} \) sign refined grid chain complexes correspond precisely to the \( 2^{l-1} \) \( \mathbb{Z} \)-valued \( (l+1) \)-graded homology groups \( \hat{\text{HFL}}(L, \mathbb{Z}) \).

Once again, it is an interesting question whether \( \hat{\text{HFG}}(L, \mathbb{Z}) \) is isomorphic to the canonical \( \text{HFL}(L, \mathbb{Z}) \), and once again, we are unable to answer it with our present methods. It is also an interesting endeavor to find two \( l \)-component links \( L_1 \) and \( L_2 \), such that \( \hat{\text{CFK}}(L_1, \mathbb{F}_2) \) is isomorphic to \( \hat{\text{CFK}}(L_2, \mathbb{F}_2) \) as \( (l+1) \)-graded \( \mathbb{F}_2 \)-modules, there is a bijection between the set of \( 2^{l-1} \) groups \( \hat{\text{CFK}}(L_1, \mathbb{Z}) \) and the set of \( 2^{l-1} \) groups \( \hat{\text{CFK}}(L_2, \mathbb{Z}) \) such that the corresponding groups are isomorphic as bi-graded \( \mathbb{Z} \)-modules, \( \hat{\text{HFG}}(L_1, \mathbb{Z}) \) is isomorphic to \( \hat{\text{HFG}}(L_2, \mathbb{Z}) \) as \( (l+1) \)-graded \( \mathbb{Z} \)-modules, but there is no bijection between the set of \( 2^{l-1} \) groups \( \hat{\text{HFL}}(L_1, \mathbb{Z}) \) and the set of \( 2^{l-1} \) groups \( \hat{\text{HFL}}(L_2, \mathbb{Z}) \) such that the corresponding groups are isomorphic as \( (l+1) \)-graded \( \mathbb{Z} \)-modules.

This is a rather short paper. We expect the reader to be already familiar with most of [4], [5], [12]. Despite trying our level best to be as self-contained as possible, we will still be rather fast in our exposition.

**Acknowledgment.** The work was done when the author was supported by the Clay Research Fellowship. He would like to thank Robert Lipshitz, Peter Ozsváth and Zoltán Szabó for several helpful discussions. He would also like to thank the referee for providing useful comments and for pointing out the errors.
2. Floer homology

For the first part of the section, in the following few numbered paragraphs, we will briefly review the basics of Heegaard Floer homology. The interested reader is referred to [10], [9] for more details.

2.1. A Heegaard diagram is an object \( H = (\Sigma_g, \alpha_1, \ldots, \alpha_{g+k-1}, \beta_1, \ldots, \beta_{g+k-1}, X_1, \ldots, X_k, O_1, \ldots, O_k) \), where: \( \Sigma_g \) is a Riemann surface of genus \( g \); \( \alpha = (\alpha_1, \ldots, \alpha_{g+k-1}) \) is \((g + k - 1)\)-tuple of disjoint simple closed curves such that \( \Sigma_g \setminus \alpha \) has \( k \) components; \( \beta = (\beta_1, \ldots, \beta_{g+k-1}) \) is \((g + k - 1)\)-tuple of disjoint simple closed curves such that \( \Sigma_g \setminus \beta \) has \( k \) components; the \( \alpha \) circles are transverse to the \( \beta \) circles; \( X = (X_1, \ldots, X_k) \) is a \( k \)-tuple of points such that each component of \( \Sigma_g \setminus \alpha \) has an \( X \) marking, and each component of \( \Sigma_g \setminus \beta \) has an \( X \) marking; \( O = (O_1, \ldots, O_k) \) is a \( k \)-tuple of points such that each component of \( \Sigma_g \setminus \alpha \) has an \( O \) marking, and each component of \( \Sigma_g \setminus \beta \) has an \( O \) marking; and the diagram is assumed to be admissible, which is a technical condition that we will describe later.

2.2. A Heegaard diagram represents an oriented link \( L \) inside a three-manifold \( Y \) in the following way: the pair \((\Sigma_g, \alpha)\) represents genus \( g \) handlebody \( U_\alpha \); the pair \((\Sigma_g, \beta)\) represents genus \( g \) handlebody \( U_\beta \); the ambient three-manifold \( Y \) is obtained by gluing \( U_\alpha \) to \( U_\beta \) along \( \Sigma_g \); the \( X \) markings are joined to the \( O \) markings by \( k \) simple oriented arcs in the complement of the \( \alpha \) circles, and the interiors of the \( k \) arcs are pushed slightly inside the handlebody \( U_\alpha \); the \( O \) markings are joined to the \( X \) markings by \( k \) simple oriented arcs in the complement of the \( \beta \) circles, and the interiors of the \( k \) arcs are pushed slightly inside the handlebody \( U_\beta \); the union of these \( 2k \) oriented arcs is the oriented link \( L \). Let the link have \( l \) components, and let \( 2m_i \) be the number of arcs that represent \( L_i \), the \( i \)th component of the link \( L \). Therefore, \( k = \sum_i m_i \geq l \). In [12], the case \( k = l \) is studied, and in [8], the subcase \( k = l = 1 \) is dealt with. We will always assume that \( L_i \) is null-homologous in \( Y \), for each \( i \).

2.3. Consider \((g + k - 1)\)-tuples of points \( x = (x_1, \ldots, x_{g+k-1}) \), such that each \( \alpha \) circle contains some \( x_i \), and each \( \beta \) circle contains some \( x_j \). To each such tuple \( x \), we can associate a Spin\(^C\) structure \( s_x \) on the ambient three-manifold \( Y \). In all the three-manifolds that we will consider, we will be interested in a canonical torsion Spin\(^C\) structure. In particular, for \( Y = \#^n S^3 \times S^2 \), we will be interested in the unique torsion Spin\(^C\) structure. A generator is a \((g + k - 1)\)-tuple \( x \) of the type described above, such that \( s_x \) is the canonical Spin\(^C\) structure. The set of all generators in a Heegaard diagram \( H \) is denoted by \( G_H \). An elementary domain is a component of \( \Sigma_g \setminus (\alpha \cup \beta) \). A domain \( D \) joining a generator \( x \) to a generator \( y \), is a 2-chain generated by elementary domains such that \( \partial(\partial D|_\alpha) = y - x \). The set of all domains joining \( x \) to \( y \) is denoted by \( D(x, y) \). A periodic domain \( P \) is a 2-chain generated by elementary domains such that \( \partial(\partial P|_\alpha) = 0 \). The set of periodic domains is denoted by \( \mathcal{P}_H \), and there is a natural bijection between \( \mathcal{P}_H \) and \( D(x, x) \) for any generator \( x \). If \( D \) is a domain, and if \( p \) is a point lying in an elementary domain, then \( n_p(D) \) denotes the coefficient of the 2-chain \( D \) at that elementary domain. Let \( n_X(D) = \sum_i n_{X_i}(D) \) and \( n_O(D) = \sum_i n_{O_i}(D) \). Furthermore, let \( n_{X,j}(D) \) denote the sum of \( n_{X_j}(D) \) for all the \( X_j \) markings that lie in \( L_i \), and let \( n_{O,j}(D) \) denote the sum of \( n_{O_j}(D) \) for all the \( O_j \) markings that lie in \( L_i \). A domain is said to be non-negative if it has non-negative coefficients in every elementary
domain. A domain \( D \) is said to be empty if \( n_{X,i}(D) = n_{O,i}(D) = 0 \) for all \( i \).

A Heegaard diagram is called admissible if there are no non-negative, non-trivial empty periodic domains. The set of all empty domains in \( \mathcal{D}(x,y) \) is denoted by \( \mathcal{D}^0(x,y) \), and the set of all empty periodic domains is denoted by \( \mathcal{P}_{\mathcal{H}}^0 \). The set \( \mathcal{P}_{\mathcal{H}}^0 \) forms a free abelian group of rank \( b_1(Y) + l - 1 \).

2.4. Every domain \( D \) has an integer valued Maslov index \( \mu(D) \) associated to it, which satisfies certain properties that we will mention as we need them. In all the Heegaard diagrams that we will consider, the following additional restrictions will hold: if \( P \in \mathcal{D}(x,x) \), then \( \mu(P) = 2n_O(P) \) and, since \( L_i \) is null-homologous in \( Y \), \( n_{X,i}(P) = n_{O,i}(P) \) for all \( i \). This allows us to define \( (l+1) \) relative gradings. Given two generators \( x, y \), choose a domain \( D \in \mathcal{D}(x,y) \) (since \( a_x = a_y \), the set \( \mathcal{D}(x,y) \) is non-empty), and let the relative Maslov grading \( M(x,y) = \mu(D) - 2n_O(D) \), and let the relative Alexander grading \( A_i(x,y) = n_{X,i}(D) - n_{O,i}(D) \). In certain situations, with certain additional hypotheses, these gradings can be lifted to absolute gradings. However, for convenience, we will now, the reader is strongly advised to read Section 3 of [10]. Let \( \mathcal{P}_{\mathcal{H}}^0 \).

For the analytical aspects of the theory, which we are about to describe now, the reader is strongly advised to read Section 3 of [10]. Let \( \text{Sym}^{g+k-1}(\Sigma_g) \) be \((g+k-1)\)-fold symmetric product, and let \( J_s \) be a path of nearly symmetric almost complex structures on it, obtained as a small perturbation of the constant path of nearly symmetric almost complex structure \( \text{Sym}^{g+k-1}(j) \), where \( j \) is a fixed complex structure on \( \Sigma_g \), such that \( J_s \) achieves certain transversality that we will describe later. The subspace \( T_\alpha = a_1 \times \cdots \times a_{g+k-1} \) and \( T_\beta = \beta_1 \times \cdots \times \beta_{g+k-1} \) are two totally real tori. Notice that \( \mathcal{G}_{\mathcal{H}} \) is in a natural bijection with a subset of \( T_\alpha \cap T_\beta \).

Fix \( p > 2 \). Given a domain \( D \in \mathcal{D}(x,y) \), let \( \mathcal{B}(D) \) be the space of all \( L_1^p \) maps \( u \) from \([0,1] \times \mathbb{R} \subset \mathbb{C} \) to \( \text{Sym}^{g+k-1}(\Sigma_g) \), such that: \( u \) maps \( \{0\} \times \mathbb{R} \) to \( T_\alpha \); \( u \) maps \( \{1\} \times \mathbb{R} \) to \( T_\beta \); \( \lim_{t \to -\infty} u(s + it) = x \) with a certain pre-determined asymptotic behavior; \( \lim_{t \to -\infty} u(s + it) = y \) with a certain pre-determined asymptotic behavior; for any point \( p \) in any elementary domain, the algebraic intersection number between \( u \) and \( \{p\} \times \text{Sym}^{g+k-2}(\Sigma_g) \) is \( n_p(D) \), or, as it is colloquially stated, the domain \( D \) is the shadow of \( u \). Oszváth and Szabó define a vector bundle \( \mathcal{L} \) over \( \mathcal{B}(D) \), and a section \( \xi \) of that bundle depending on \( J_s \), such that the linearization of the section \( D_\xi u \) is a Fredholm operator for every \( u \in \mathcal{B}(D) \). The transversality of the path \( J_s \) that we mentioned earlier, simply means that the Fredholm section \( \xi \) is transverse to the 0-section of \( \mathcal{L} \). The intersection of \( \xi \) and the 0-section is denoted by \( \mathcal{M}_{J_s}(D) \), and it consists precisely of the \( J_s \)-holomorphic maps. There is an \( \mathbb{R} \) action on \( \mathcal{M}_{J_s}(D) \) coming from the \( \mathbb{R} \) action on \([0,1] \times \mathbb{R} \), and the unparametrized moduli space is denoted by \( \overline{\mathcal{M}}_{J_s}(D) = \mathcal{M}_{J_s}(D)/\mathbb{R} \). The virtual index bundle of the linearization map \( D_\xi \) gives an element of the \( K \)-theory of \( \mathcal{B}(D) \). Its dimension is the expected dimension of the moduli space \( \mathcal{M}_{J_s}(D) \), and this dimension is in fact the Maslov index \( \mu(D) \), that we had mentioned earlier. The determinant line bundle of the index bundle, henceforth denoted by \( \text{det}(D) \), turns out to be a trivializable line bundle over \( \mathcal{B}(D) \). Therefore, a choice of a nowhere vanishing section on
the trivializable line bundle \( \det(D) \), produces an orientation of the moduli space \( \mathcal{M}_{\hat{s}}(D) \), and hence an orientation of the unparametrized moduli space \( \hat{\mathcal{M}}_{\hat{s}}(D) \).

2.6. If \( D_1 \in \mathcal{D}(x, y) \) and \( D_2 \in \mathcal{D}(y, z) \) are domains, then the 2-chain \( D_1 + D_2 \) lies in \( \tau_2(x, z) \). The asymptotic behaviors that we had mentioned earlier, along with some globally pre-determined choices, allows us to get a pre-gluing map from \( \mathcal{B}(D_1) \times \mathcal{B}(D_2) \) to \( \mathcal{B}(D_1 + D_2) \). The pullback of the line bundle \( \det(D_1 + D_2) \) over \( \mathcal{B}(D_1) \times \mathcal{B}(D_2) \) can be canonically identified with the line bundle \( \det(D_1) \wedge \det(D_2) \) over \( \mathcal{B}(D_1) \times \mathcal{B}(D_2) \) by linearized gluing. An orientation system \( \sigma \) is a choice of a nowhere vanishing section \( \sigma(D) \) of the trivializable line bundle \( \det(D) \) over \( \mathcal{D}(x, y) \), and for every pair of generators \( x, y \in \mathcal{G}_\mathcal{H} \), such that if \( D_1 \in \mathcal{D}(x, y) \) and \( D_2 \in \mathcal{D}(y, z) \), then \( \sigma(D_1) \wedge \sigma(D_2) = \sigma(D_1 + D_2) \). Therefore, two orientation systems \( \sigma_1 \) and \( \sigma_2 \) disagree on \( D_1 + D_2 \) if and only if they disagree on exactly one of the two domains \( D_1 \) and \( D_2 \).

2.7. The following describes a method to find all possible orientation systems. Fix a generator \( x \in \mathcal{G}_\mathcal{H} \), and for every other generator \( y \), choose a domain \( D_y \in \mathcal{D}(x, y) \). Then choose a set of periodic domains \( P_1, \ldots, P_m \), which freely generate \( \mathcal{P}_\mathcal{H} \). Orient the determinant line bundles over the domains \( D_y \) and \( P_j \) arbitrarily. Since any domain \( D \in \mathcal{D}(y, z) \) can be written uniquely as \( D = \sum_j a_j P_j + D_z - D_y \), this choice uniquely specifies an orientation system. Thus, an orientation system is specified by its values on certain domains \( D_y \) and certain periodic domains \( P_j \). This allows us to define a chain complex over \( \mathbb{Z} \), and it will turn out that the gauge equivalence class of the sign assignment on the chain complex is independent of the orientations of the line bundles \( \det(D_y) \). Therefore, declare two orientations systems to be strongly equivalent if they agree on all the periodic domains in \( \mathcal{P}_\mathcal{H} \) (or in other words, they agree on all the periodic domains \( P_1, \ldots, P_m \)). There is a second notion of equivalence, which is of some importance to us, whereby two orientation systems are declared to be weakly equivalent if they agree on all the periodic domains in \( \mathcal{P}_\mathcal{H}^0 \). Let \( \hat{\mathcal{O}}_\mathcal{H} \) denote the set of weak equivalence classes of orientation systems. Then \( \hat{\mathcal{O}}_\mathcal{H} \) is a torseur over \( \text{Hom}(\mathcal{P}_\mathcal{H}^0, \mathbb{Z}/2\mathbb{Z}) \), so there are exactly \( 2^{\mu(1)}(3)^{l-1} \) weak equivalence classes of orientation systems.

If \( D \in \mathcal{D}(x, y) \) is a domain, its unparametrized moduli space \( \hat{\mathcal{M}}_{\hat{s}}(D) \) is a compact, \( (\mu(D) - 1) \)-dimensional manifold with corners by Gromov compactness and the fact that \( J_\mathcal{H} \) achieves transversality; an orientation system \( \sigma \) determines an orientation on \( \hat{\mathcal{M}}_{\hat{s}}(D) \). Therefore, if \( \mu(D) = 1 \), then \( \hat{\mathcal{M}}_{\hat{s}}(D) \) is a compact oriented zero-dimensional manifold with corners, or in other words, it is a finite number of signed points. Let \( c(D) \) be the total number of points, counted with sign. The cornerstone of Floer homology in the present setting, is the following lemma.

**Lemma 2.1.** If \( D \in \mathcal{D}(x, y) \) is a domain with \( \mu(D) = 2 \), then \( \hat{\mathcal{M}}_{\hat{s}}(D) \) is an oriented one-dimensional manifold. Furthermore, if \( D = D_1 + D_2 \), where \( D_1 \in \mathcal{D}(x, z) \) and \( D_2 \in \mathcal{D}(z, y) \), with \( \mu(D_1) = 1 \) and \( \mu(D_2) = 1 \), then the total number of points in the boundary of \( \hat{\mathcal{M}}_{\hat{s}}(D) \) that correspond to a decomposition of \( D \) as \( D_1 + D_2 \), when counted with signs induced from the orientation of \( \hat{\mathcal{M}}_{\hat{s}}(D) \), equals \( c(D_1) c(D_2) \).

An immediate corollary is the following: if all the points in the boundary of \( \hat{\mathcal{M}}_{\hat{s}}(D) \) correspond to such a decomposition — in other words, if bubbling and
boundary degenerations can be ruled out — then the sum $\sum c(D_1)c(D_2)$ over all such possible decompositions is zero. This allows us to define the following $(l + 1)$-graded chain complex over $\mathbb{Z}$. This is a well-known chain complex, and it was first defined by Ozsváth and Szabó for $k = 1$. However, for a general value of $k$, the chain complex was originally not defined over $\mathbb{Z}$. There are certain subtleties that need to be resolved before the minus version can be defined over $\mathbb{Z}$, namely, we have to orient the boundary degenerations in a consistent manner such that the proofs of Theorems 2.4, 2.5, and 2.7 go through; however, those issues do not appear when we work only in the hat version.

**Definition 2.2.** Given an admissible Heegaard diagram $\mathcal{H}$ for $L$ and an orientation system $\sigma \in \hat{\mathcal{O}}_{\mathcal{H}}$, let $\overline{CFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma)$ be the chain complex freely generated over $\mathbb{Z}$ by the elements of $\mathcal{G}_{\mathcal{H}}$, with the $(l + 1)$ gradings given by $M, A_1, \ldots, A_l$, and the boundary map given by

$$\partial x = \sum_{y \in \mathcal{G}_{\mathcal{H}}} \sum_{D \in \mathcal{D}^0(x,y), \mu(D) = 1} c(D)y.$$  

**Lemma 2.3.** The map $\partial$ on $\overline{CFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma)$ reduces the Maslov grading by 1, keeps all Alexander gradings fixed, and satisfies $\partial^2 = 0$.

**Proof.** The claims regarding the gradings follow directly from the definitions. To prove that $\partial^2 = 0$, by Lemma 2.1 we only need to show that for any empty Maslov index 2 domain $D$, the boundary points of $\hat{\mathcal{M}}(D)$ do not correspond to bubbling or boundary degenerations. However, the shadow of a bubble or a boundary degeneration is a 2-chain in the Heegaard diagram, whose boundary lies entirely within the $\alpha$ circles, or entirely within the $\beta$ circles. Any such 2-chain must have non-zero coefficient at some $X$ marking, and therefore by positivity of domains, the original domain must also have non-zero coefficient at that $X$ marking, and therefore, could not have been empty. 

Even though we did not specify in the notations, $\overline{CFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma)$ might also depend on the path of almost complex structures $J_s$ on $\text{Sym}^{\hat{k}+k-1}(\Sigma_g)$. However, the homology $H_s(\overline{CFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma))$, as an $(l + 1)$-graded object, depends only on the link $L$, the numbers of $X$ markings, $m_i$, that lie on the $i$th link component for each $i$, and the weak equivalence class of the orientation system $\sigma$.

**Theorem 2.4.** For a fixed Heegaard diagram $\mathcal{H}$ and a fixed path of almost complex structures $J_s$, if $\sigma_1$ and $\sigma_2$ are weakly equivalent, then the two chain complexes $\overline{CFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma_1)$ and $\overline{CFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma_2)$ are isomorphic. If $\mathcal{H}_1$ and $\mathcal{H}_2$ are two different Heegaard diagrams for the same link $L$, such that in both $\mathcal{H}_1$ and $\mathcal{H}_2$, the $i$th link component $L_i$ is represented by $m_i$ $X$ markings and $m_i$ $O$ markings, and if $J_{s,1}$ and $J_{s,2}$ are two paths of almost complex structures on the two symmetric products, then there is a bijection $f$ between $\hat{\mathcal{O}}_{\mathcal{H}_1}$ and $\hat{\mathcal{O}}_{\mathcal{H}_2}$, such that for every $\sigma \in \hat{\mathcal{O}}_{\mathcal{H}_1}$, the homology $H_s(\overline{CFL}_{\mathcal{H}_1}(L, \mathbb{Z}, \sigma))$ is isomorphic to the homology $H_s(\overline{CFL}_{\mathcal{H}_2}(L, \mathbb{Z}, f(\sigma)))$, as $(l + 1)$-graded groups.

**Proof.** This is neither a new type of a theorem, nor a new idea of a proof. For the first part, let $\sigma_1$ and $\sigma_2$ be two weakly equivalent orientation systems. We are going to define a map $t : \mathcal{G}_{\mathcal{H}} \to \{\pm 1\}$ in the following way. Call two generators $x$ and $y$ to be connected if there is an empty domain $D \in \mathcal{D}^0(x,y)$. For each connected component of $\mathcal{G}_{\mathcal{H}}$, choose a generator $x$ in that connected component, and declare $t(x) = 1$. For every other generator $y$ in that connected component, choose an empty domain $D_y \in \mathcal{D}^0(x,y)$, and declare $t(y) = 1$ if $\sigma_1(D_y)$ agrees with $\sigma_2(D_y)$,
and $t(y) = -1$ otherwise. Since $\phi_1$ and $\phi_2$ agree on all the empty periodic domains, $t$ is a well-defined function. Furthermore, for any empty Maslov index 1 domain $D \in \mathcal{D}^0(x, y)$, the contribution $c_{\phi_1}(D)$ coming from $\phi_1$ is related to the contribution $c_{\phi_2}(D)$ coming from $\phi_2$ by the equation $c_{\phi_1}(D) = t(x) t(y) c_{\phi_2}(D)$. That shows that the two chain complexes are isomorphic via the map $x \mapsto t(x)$.

For the second part of the theorem, recall the well known fact that if two Heegaard diagrams $\mathcal{H}_1$ and $\mathcal{H}_2$ represent the same link $L$, such that each component of the link has the same number of $X$ and $O$ markings in both the Heegaard diagrams, then they can be related to one another by a sequence of isotopies, handleslides, and stabilizations. This essentially follows from [10, Proposition 7.1] and [3, Lemma 2.4]. However, during the isotopies, we do not require the stabilizations. This essentially follows from [10, Proposition 7.1] and [3, Lemma 2.4]. However, during the isotopies, we do not require the α circles to remain transverse to the β circles. Therefore, we can assume that $\mathcal{H}_1$ and $\mathcal{H}_2$ are related by one of the following elementary moves: changing the path of almost complex structures $J_s$ by an isotopy $J_{s,t}$; a stabilization in a neighborhood of a marked point; a sequence of isotopies and handleslides of the α circles in the complement of the marked points; or a sequence of isotopies and handleslides of the β circles in the complement of the marked points.

For the case of a stabilization, or an isotopy of the path of almost complex structures, there is a natural identification between $\mathcal{P}^0_{\mathcal{H}_1}$ and $\mathcal{P}^0_{\mathcal{H}_2}$, and a natural identification of the determinant line bundles over the corresponding empty periodic domains. Since a weak equivalence class of an orientation system is determined by its values on the empty periodic domains, this produces a natural identification between $\mathcal{O}_{\mathcal{H}_1}$ and $\mathcal{O}_{\mathcal{H}_2}$. The proof that the two homologies are isomorphic for the corresponding orientation systems is immediate for the case of a stabilization, and follows from the usual arguments of [10] for the other cases. We do not encounter any new problems, since boundary degenerations are still ruled out by the marked points.

For the remaining cases, namely, the case of isotopies and handleslides of α circles or β circles, the isomorphism is established by counting holomorphic triangles. Let us assume that the α circles are changed to the γ circles by a sequence of isotopies and handleslides in the complement of the marked points. Out of the $2^{t+k^k}$ weak equivalence classes of orientation systems in the Heegaard diagram $\mathcal{H}_3 = (\Sigma, \gamma, \alpha, \beta, \gamma, \alpha, \beta)$, there is a unique one $\phi_3$, for which the homology of $\mathcal{H}_3$ is torsion-free. Each empty periodic domain in $\mathcal{H}_2$ can be written uniquely as a sum of empty periodic domains in $\mathcal{H}_1$ and $\mathcal{H}_3$. Therefore, we have a natural bijection between $\mathcal{O}_{\mathcal{H}_1}$ and $\mathcal{O}_{\mathcal{H}_2}$: given an orientation system $\phi \in \mathcal{O}_{\mathcal{H}_1}$, we can patch it with $\phi_3$, to get an orientation system $f(\phi) \in \mathcal{O}_{\mathcal{H}_2}$. The triangle map, evaluated on the top generator of the homology of $\mathcal{H}_3$, provides the required isomorphism between the homology of $\mathcal{H}_1$ and the homology of $\mathcal{H}_2$, for the corresponding orientation systems. The same proof from [10] goes through without any problems since we do not encounter any boundary degenerations.

Let $\vec{m} = (m_1, \ldots, m_l)$. The above theorem shows that $H_*(\overline{CFL}(L, \mathbb{Z}, \phi))$ is an invariant of the link $L$ inside the three-manifold, a choice of a weak equivalence class of an orientation system $\phi$, and the vector $\vec{m}$. Let us henceforth denote the homology as $\overline{HFL}_{\vec{m}}(L, \mathbb{Z}, \phi)$. We now investigate the dependence of $\overline{HFL}_{\vec{m}}(L, \mathbb{Z}, \phi)$ on $\vec{m}$. 

\[\]
Theorem 2.5. Let $\mathcal{H}$ be a Heegaard diagram for a link $L$, where the $i^{th}$ component $L_i$ is represented by $m_i$ $X$ markings and $m_i$ $O$ markings, and let $\mathcal{H}'$ be a Heegaard diagram for the same link, where $L_i$ is represented by $m'_i = (m_i + \delta_{i0})$ $X$ markings and $m'_i$ $O$ markings, for some fixed $i_0$. Then there is a bijection $f$ between $\hat{O}_\mathcal{H}$ and $\hat{O}_{\mathcal{H}'}$ such that for every weak equivalence class of orientation system $\sigma$, $\hat{HFL}_{\mathcal{H}}(L, \mathbb{Z}, \sigma)$ is isomorphic to $\hat{HFL}_{\mathcal{H}'}(L, \mathbb{Z}, f(\sigma)) \otimes \mathbb{Q}_{i_0}$ as $(l+1)$-graded groups.

Proof. Consider the Riemann sphere $S$ with one $\alpha$ circle and one $\beta$ circle, intersecting each other at two points $p$ and $q$. Put two $X$ markings, one $O$ marking and one $W$ marking, one in each of the four elementary domains of $S \setminus (\alpha \cup \beta)$, such that the boundary of either of the two elementary domains that contain an $X$ marking runs from $p$ to $q$ along the $\alpha$ circle, and from $q$ to $p$ along the $\beta$ circle. Remove a small disk in the neighborhood of the point $W$. In the Heegaard diagram $\mathcal{H}$, choose an $X$ marking that lies in $L_{i_0}$, and remove a small disk in the neighborhood of that point. Then connect the diagram $\mathcal{H}$ to the sphere $S$ via the ‘neck’ $S^1 \times [0, T]$ to get a new Heegaard diagram for the same link, where $L_i$ is represented by $m'_i$ $X$ markings, and $m'_i$ $O$ markings. This process is shown in Figure 2.1. By Theorem 2.4, we can assume that the new Heegaard diagram is $\mathcal{H}'$. There is a natural correspondence between $\mathcal{P}^n_H$ and $\mathcal{P}^n_{H'}$, and this induces the bijection $f$ between $\hat{O}_\mathcal{H}$ and $\hat{O}_{\mathcal{H}'}$.

Fix $\sigma \in \hat{O}_\mathcal{H}$. As $(l + 1)$-graded groups, $\overline{CFH}_{\mathcal{H}}(L, \mathbb{Z}, \sigma) = \overline{CFH}_{\mathcal{H}'}(L, \mathbb{Z}, f(\sigma)) \otimes (\mathbb{Z} \oplus \mathbb{Z})$, where one $\mathbb{Z}$ corresponds to all the generators that contain the point $p$, and has $(M, A_1, \ldots, A_l)$ multi-grading $(0, 0, \ldots, 0)$, and the other $\mathbb{Z}$ corresponds to all the generators that contain the point $q$, and has $(M, A_1, \ldots, A_l)$ multi-grading $(-1, -\delta_{i01}, \ldots, -\delta_{il})$. We simply need to show that the same identity holds as chain complexes. For this, it is enough to show that there are no boundary maps from the generators that contain the point $p$ to the generators that contain the point $q$.

Following the arguments from [12], we extend the ‘neck length’ $T$, and move the point $W$ close to the $\alpha$ circle in $S$. After choosing $T$ sufficiently large and $W$ sufficiently close to the $\alpha$ circle, if there is an empty positive Maslov index 1...
domain $D$, joining a generator containing $p$ to a generator containing $q$, such that $c(D) \neq 0$, then $D$ must correspond to a positive, Maslov index 2 domain in $\mathcal{H}$ that avoids all the $O$ markings and whose boundary lies entirely on the $\alpha$ circles. However, any non-trivial domain in $\mathcal{H}$ whose boundary lies entirely on the $\alpha$ circles must have non-zero coefficients at some $O$ marking, thus producing a contradiction, and thereby finishing the proof.

Henceforth, denote $\widehat{HF}(1_{\ldots}, 1)(L, \mathbb{Z}, o)$ by $\widehat{HF}(L, \mathbb{Z}, o)$. Theorems 2.4 and 2.5 imply:

**Theorem 2.6.** Let $\mathcal{H}$ be a Heegaard diagram for a link $L \subset S^3$ with $l$ components, such that the $i^{th}$ component $L_i$ is represented by exactly $m_i$ $X$ markings, and exactly $m_i$ $O$ markings. Then the $2^{l-1}$ homology groups $\widehat{HF}(L, \mathbb{Z}, o)$ are isomorphic to the $2^{l-1}$ groups $\widehat{HF}(L, \mathbb{Z}, o) \otimes_1 (\otimes^{m_i-1} Q_i)$.

We are almost done with the construction that we had set out to do. Given a link $L \subset S^3$ with $l$ components, we have produced $2^{l-1}$ $Z$-valued $(l+1)$-graded homology groups $\widehat{HF}(L, \mathbb{Z}, o)$. We would like to finish this section by showing that when we combine the $l$ Alexander gradings into one, then we get the $2^{l-1}$ $Z$-valued bi-graded homology groups $\widehat{HF}(L, \mathbb{Z}, o)$. Recall that the groups $\widehat{HF}(L, \mathbb{Z}, o)$ are constructed by viewing the link $L \subset Y$ as a knot in $Y^#(S^1 \times S^2)$, and then looking at the knot Floer homology. Therefore, the following lemma is all that we need.

**Theorem 2.7.** Let $\mathcal{H}$ be a Heegaard diagram for a link $L \subset Y$ with $(l+1)$ components, such that each component is represented by one $X$ and one $O$ marking. Let $\tilde{L}$ be the link with $l$ components in $Y^#(S^1 \times S^2)$, whose $l^{th}$ component $\tilde{L}_i$ is obtained by connect summing $L_{l+1}$ and $L_i$ through the one-handle, and let $\tilde{\mathcal{H}}$ be a Heegaard diagram for $\tilde{L}$, where $\tilde{L}_i$ is represented by $(1+\delta_i)$ $X$ markings and $(1+\delta_i)$ $O$ markings. Then, there is a bijection $f$ between $\mathcal{H}$ and $\tilde{\mathcal{H}}$, such that for all $o \in \tilde{\mathcal{H}}$, $H_*(\tilde{\mathcal{CFL}}_{\tilde{L}}(L, \mathbb{Z}, f(o))) = \widehat{HF}(L, \mathbb{Z}, o) \otimes Q_1$ as $(l+1)$-graded groups, where the $(l+1)$ gradings on the left hand side are $(M, A_1, \ldots, A_{l-1}, A_{l+1})$.

**Proof.** This proof is very similar to the proof of Theorem 2.5. Once more, consider the Riemann sphere $\mathcal{S}$ with one $\alpha$ circle and one $\beta$ circle, intersecting each other at two points $p$ and $q$. Put two $X$ markings and two $W$ marking, one in each of the four elementary domains of $\mathcal{S} \setminus (\alpha \cup \beta)$, such that the boundary of either of the two elementary domains that contain an $X$ marking runs from $p$ to $q$ along the $\alpha$ circle, and from $q$ to $p$ along the $\beta$ circle. Remove two small disks in the neighborhoods of the $W$ markings. In the Heegaard diagram $\mathcal{H}$, remove two small disks in the neighborhoods of the the two $X$ markings that lie in $L_{l+1}$ and $L_l$. Then connect $\mathcal{H}$ to the sphere $\mathcal{S}$ via the two ‘necks,’ $S^1 \times [0, T_1]$ and $S^1 \times [0, T_2]$, as shown in Figure 2.2. The resulting picture is a Heegaard diagram for the link $\tilde{L} \subset Y^#(S^1 \times S^2)$, where the $i^{th}$ component $\tilde{L}_i$ is represented by $(1+\delta_i)$ $X$ markings and $(1+\delta_i)$ $O$ markings. By the virtue of Theorem 2.7 we can assume that this Heegaard diagram is $\tilde{\mathcal{H}}$.

An empty periodic domain in $\mathcal{H}$ gives rise to an empty periodic domain in $\tilde{\mathcal{H}}$. In the other direction, an empty periodic domain in $\tilde{\mathcal{H}}$ gives rise to a periodic domain in $\mathcal{H}$ which does not pass through any of the $O$ markings. Since each component of the link $L$ is null-homologous in $Y$, such a periodic domain is an empty periodic
domain. Therefore, there is a natural correspondance between the empty periodic domains of $\mathcal{H}$ and $\tilde{\mathcal{H}}$, and this induces the bijection $f$ between $\tilde{\mathcal{O}}_{\mathcal{H}}$ and $\tilde{\mathcal{O}}_{\tilde{\mathcal{H}}}$.

Fix $\circ \in \tilde{\mathcal{O}}_{\mathcal{H}}$. It is immediate that as $(l + 1)$-graded groups, $\tilde{\text{CFL}}_{\tilde{\mathcal{H}}}(L, \mathbb{Z}, f(\circ)) = \tilde{\text{CFL}}_{\mathcal{H}}(L, \mathbb{Z}, \circ) \otimes \mathbb{Q}_l$. However, quite like the case of Theorem 2.5, for sufficiently large ‘neck lengths’ $T_1$ and $T_2$, and with the two $W$ markings sufficiently close to the $\alpha$ circle on $S$, the above identity holds even as chain complexes. □

Before we conclude this section, a note regarding absolute gradings is due. So far, we have worked with relative Maslov grading and relative Alexander gradings. However, for links in $S^3$, and for links in $\#^m(S^1 \times S^2)$ that we obtain from links in $S^3$ by the connect sum process described in Theorem 2.7, there is a well-defined way to lift these gradings to absolute gradings, as defined in [11, Theorem 7.1], [8, Subsections 3.3 and 3.4] and [12, Lemma 4.6 and Equation 24]. Since this is an oft-studied scenario, for such links, let us improve the earlier theorems, and henceforth work with absolute gradings.

**Lemma 2.8.** For links in $\#^m(S^1 \times S^2)$ that come from links in $S^3$ by the connect sum operation as described in Theorem 2.7, the isomorphisms in Theorems 2.4, 2.5, 2.6 and 2.7 preserve the absolute gradings.

**Proof.** Recall that the isomorphisms in question come from chain maps that preserve the relative gradings. Therefore, each such chain map must shift each absolute grading by a fixed integer on the entire chain complex. We want to show that each of these shifts is zero.

Since the absolute gradings are defined on the generators themselves, this shift is unchanged if instead of working over $\mathbb{Z}$, we tensor everything with $\mathbb{F}_2$ and work over $\mathbb{F}_2$. However, since the Heegaard Floer homology of $\#^m(S^1 \times S^2)$ is non-trivial over $\mathbb{F}_2$, in each case, the homology of the entire chain complex is non-trivial over $\mathbb{F}_2$. Furthermore, the maps induced on the homology over $\mathbb{F}_2$ preserve the absolute gradings [11, 8, 12]. Therefore, all the shifts are zero, and each of the chain maps preserves all the gradings. □
3. Grid diagrams

A planar grid diagram of index $N$ is the square $S = [0, N] \times [0, N] \subset \mathbb{R}^2$, with the following additional structures: if $1 \leq i \leq N$, the horizontal line $y = (i - 1)$ is called $\alpha_i$, the $i^{th}$ $\alpha$ arc, and the vertical line $x = (i - 1)$ is called $\beta_i$, the $i^{th}$ $\beta$ arc; there are $2N$ markings, denoted by $X_1, \ldots, X_N, O_1, \ldots, O_N$, such that each component of $S \setminus (\bigcup_i \alpha_i)$ contains one $X$ marking and one $O$ marking, and each component of $S \setminus (\bigcup_i \beta_i)$ contains one $X$ marking and one $O$ marking.

A toroidal grid diagram of index $N$ is obtained from a planar grid diagram of the same index by identifying the opposite sides of the square $S$ to form a torus $T$. A careful reader will immediately observe that this creates a Heegaard diagram $\mathcal{H}$ for some link $L$ in $S^3$, and for the rest of the section, we will work with this Heegaard diagram. The $\alpha$ arcs and the $\beta$ arcs become full circles, and they are the $\alpha$ circles and the $\beta$ circles respectively; the $N$ components of $T \setminus (\bigcup_i \alpha_i)$ are called the horizontal annuli, and each of them contains one $X$ marking and one $O$ marking; the horizontal annulus with $\alpha_i$ as the circle on the bottom is called the $i^{th}$ horizontal annulus, and is denoted by $H_i$; the $N$ components of $T \setminus (\bigcup_i \beta_i)$ are called the vertical annuli, and each of them also contains one $X$ marking and one $O$ marking; the vertical annulus with $\beta_i$ as the circle on the left is called the $i^{th}$ vertical annulus, and is denoted by $V_i$; the $N^2$ components of $T \setminus (\bigcup_i (\alpha_i \cup \beta_i))$ are the elementary domains. Therefore, the link $L$ that the toroidal grid diagram represents, can be obtained in the following way. We assume that the toroidal grid diagram comes from a planar grid diagram on the square $S$. Then in each component of $S \setminus (\bigcup_i \alpha_i)$, we join the $X$ marking to the $O$ marking by an embedded arc, and in each component of $S \setminus (\bigcup_i \beta_i)$, we join the $O$ marking to the $X$ marking by an embedded arc, and at every crossing, we declare the arc that joins $O$ to $X$ to be the overpass. Henceforth, we also assume that the link $L$ has $l$ components, and the $i^{th}$ component $L_i$ is represented by $m_i$ $X$ markings and $m_i$ $O$ markings, and $\sum_i m_i = N$.

There is only one $\text{Spin}^C$ structure, so generators in $\mathcal{G}_\mathcal{H}$ correspond to the permutations in $\mathfrak{S}_N$ as follows: a generator $x = (x_1, \ldots, x_N) \in \mathcal{G}_\mathcal{H}$ comes from the permutation $\sigma \in \mathfrak{S}_N$, where $x_i = \alpha_i \cap \beta_{\sigma(i)}$ for each $1 \leq i \leq N$. The $N$ points $x_1, \ldots, x_N$ are called the coordinates of the generator $x$.

Let $j$ be the complex structure on $T$ induced from the standard complex structure on $S \subset \mathbb{C}$, and let $J_s$ be the constant path of almost complex structure $\text{Sym}^N(j)$ on $\text{Sym}^N(T)$. After a slight perturbation of the $\alpha$ and the $\beta$ circles, we can ensure that $J_s$ achieves transversality for all domains up to Maslov index two [2 Lemma 3.10]. Henceforth, we work with these perturbed $\alpha$ and $\beta$ circles and this path of nearly symmetric almost complex structure.

Consider the $2^{l-1}$ chain complexes $\overline{CFL}_\mathcal{H}(L, \mathbb{Z}, 0)$. The boundary maps in each of the chain complexes correspond to objects called rectangles. A rectangle $R$ joining a generator $x$ to a generator $y$ is a 2-chain generated by the elementary domains of $\mathcal{H}$, such that the following conditions are satisfied: $R$ only has coefficients 0 and 1; the closure of the union of the elementary domains where $R$ has coefficient 1 is a disk embedded in $T$ with four corners, or in other words, it looks like a rectangle; the top-right corner and the bottom-left corner of $R$ are coordinates of $x$; the top-left corner and the bottom-right corner of $R$ are coordinates of $y$; the generators $x$ and $y$ share $(N - 2)$ coordinates; and $R$ does not contain any coordinates of $x$ or any coordinates of $y$ in its interior. It is easy to check that the rectangles are
precisely the positive Maslov index one domains. We denote the set of all rectangles joining \(x\) to \(y\) by \(R(x, y) \subset D(x, y)\). The set \(R(x, y)\) is empty unless \(x\) and \(y\) differ in exactly two coordinates, and even then, \(|R(x, y)| \leq 2\).

**Lemma 3.1.** [3, Theorem 1.1] If \(D \in D(x, y)\) is a domain with \(\mu(D) \leq 0\), then the unparametrized moduli space \(\hat{\mathcal{M}}_{J, \tau}(D)\) is empty. If \(D \in D(x, y)\) is a Maslov index one domain such that \(\hat{\mathcal{M}}_{J, \tau}(D)\) is non-empty, then \(D\) is a rectangle. Conversely, if \(R \in \mathcal{R}(x, y)\) is a rectangle, then \(\hat{\mathcal{M}}_{J, \tau}(R)\) consists of exactly one point, and hence \(|c(R)| = 1\).

If \(D \in D(x, y)\), we say that \(D\) can be decomposed as a sum of two rectangles if there exists a generator \(z \in \mathcal{G}_\tau\) and rectangles \(R_1 \in \mathcal{R}(x, z)\) and \(R_2 \in \mathcal{R}(z, y)\) such that \(D = R_1 + R_2\). It is easy to check that the domains that can be decomposed as sums of two rectangles are precisely the positive Maslov index two domains. For any generator \(x \in \mathcal{G}_\tau\), there are exactly \(2N\) Maslov index two positive domains in \(D(x, x)\), namely the ones coming from the horizontal annuli \(H_1, \ldots, H_N\) and the vertical annuli \(V_1, \ldots, V_N\).

**Lemma 3.2.** If \(D \in D(x, y)\) is a Maslov index two domain such that \(\hat{\mathcal{M}}_{J, \tau}(D)\) is non-empty, then \(D\) can be decomposed as a sum of two rectangles. Conversely, if \(D \in D(x, y)\) can be decomposed as a sum of two rectangles, then \(\hat{\mathcal{M}}_{J, \tau}(D)\) is a compact 1-dimensional manifold with exactly two endpoints. Furthermore, if \(x = y\) (i.e. if \(D\) comes from a horizontal or a vertical annulus), then one of the endpoints corresponds to the unique way of decomposing \(D\) as a sum of two rectangles, while the other endpoint corresponds to an \(\alpha\) or a \(\beta\) boundary degeneration; and if \(x \neq y\), then \(D\) can be decomposed as a sum of two rectangles in exactly two ways, and the two endpoints correspond to the two decompositions.

Lemma 3.1 implies that once we choose an orientation system \(\mathfrak{o}\) (and not just a weak equivalence class of orientation systems), we get a function \(c_\mathfrak{o}\) from the set of all rectangles to \(\{-1, 1\}\). Lemma 3.2 in conjunction with Lemma 2.1 implies that if a domain \(D \in D(x, y)\) can be decomposed as a sum of two rectangles in two different ways \(D = R_1 + R_2 = R_3 + R_4\), then \(c_\mathfrak{o}(R_1)c_\mathfrak{o}(R_2) = -c_\mathfrak{o}(R_3)c_\mathfrak{o}(R_4)\). This naturally leads to the definition of a sign assignment.

**Definition 3.3.** A sign assignment \(s\) is a function from the set of all rectangles to the set \(\{-1, 1\}\), such that the following condition is satisfied: if \(x, y, z, z' \in \mathcal{G}_\tau\) are distinct generators, and if \(R_1 \in \mathcal{R}(x, z)\), \(R_2 \in \mathcal{R}(z, y)\), \(R'_1 \in \mathcal{R}(x, z')\), \(R'_2 \in \mathcal{R}(z', y)\) are rectangles with \(R_1 + R_2 = R'_1 + R'_2\), then \(s(R_1)s(R_2) = -s(R'_1)s(R'_2)\). Two sign assignments \(s_1\) and \(s_2\) are said to be gauge equivalent if there is a function \(t : \mathcal{G}_\tau \to \{-1, 1\}\), such that \(s_1(R) = t(x)t(y)s_2(R)\), for all \(x, y \in \mathcal{G}_\tau\) and for all \(R \in \mathcal{R}(x, y)\).

In particular, a true sign assignment, as defined in [4, Definition 4.1], is a sign assignment. Let \(f\) be the map from the set of all orientation systems to the set of all sign assignments such that for all rectangles \(R\), \(f(\mathfrak{o})(R) = c_\mathfrak{o}(R)\). In this section, we will show that there are exactly \(2^{2N-1}\) gauge equivalence classes of sign assignments on the grid diagram. We will put a weak equivalence on the sign assignments, which is weaker than the gauge equivalence. We will prove that there are exactly \(2^{2N-1}\) weak equivalence classes of sign assignments, and the map \(f\) induces a bijection \(\tilde{f}\) between the set of weak equivalence classes of orientation systems and the set of
weak equivalence classes of sign assignments. This will allow us to combinatorially calculate $CFL(L, \mathbb{Z}, \hat{o})$ for all $o \in \hat{O}_H$, and thereby calculate $\hat{HF}(L, \mathbb{Z})$ in all the $2^{l-1}$ versions. As a corollary, this will also show that any sign assignment (in particular, the one constructed in [4]) computes $\hat{HF}(L, \mathbb{Z}, \hat{o})$ for some orientation system $\hat{o}$.

We have an explicit (although slightly artificial) correspondence between the generators in $G_H$, and the elements of the symmetric group $\mathfrak{S}_N$, whereby a permutation $\sigma \in \mathfrak{S}_N$ gives rise to the generator $x = (x_1, \ldots, x_n)$ with $x_i = \alpha_i \cap \beta_\sigma(i)$. There is the following very natural partial order on the permutations: a reduction of a permutation $\tau$ is a permutation obtained by pre-composing $\tau$ by some transposition $(i, j)$ where $i < j$ and $\tau(i) > \tau(j)$; the permutation $\sigma$ is declared to be smaller than the permutation $\tau$, if $\sigma$ can be obtained from $\tau$ by a sequence of reductions. This induces a partial order $\prec$ on the elements of $G_H$.

For $x, y \in G_H$, if $y \prec x$ and there does not exist any $z \in G_H$ such that $y \prec z \prec x$, then we say that $x$ covers $y$, and write that as $y \leftarrow x$. If we view the toroidal grid diagram as one coming from a planar grid diagram on $S = [0, N] \times [0, N]$, then $y \leftarrow x$ precisely when there is a rectangle from $x$ to $y$ contained in the subsquare $S' = [0, N-1] \times [0, N-1]$.

The poset $(G_H, \prec)$ is a well-understood object [4]. There is a unique minimum $p \in G_H$, which corresponds to the identity permutation. In particular, the Hasse diagram of $(G_H, \prec)$, viewed as an unoriented graph, is connected. There is a unique maximum $q \in G_H$, which corresponds to the permutation that maps $i$ to $(N+1-i)$. The poset is shellable, which means that there is a total ordering $\prec$ on the maximal chains, such that if $m_1$ and $m_2$ are two maximal chains with $m_1 \prec m_2$, then there exists a maximal chain $m_3 < m_2$ with $m_1 \cap m_2 \subseteq m_3 \cap m_2 = m_2 \setminus \{z\}$ for some $z \in m_2$. This in particular implies that given any two maximal chains $m_1$ and $m_2$, we can get from $m_2$ to $m_1$ via a sequence of maximal chains, where we get from one maximal chain to the next by changing exactly one element.

Given a sign assignment $s$ and a generator $x \in G_H$, we define two functions $h_{s,x}, v_{s,x} : \{1, \ldots, N\} \to \{-1, 1\}$, called the horizontal function and the vertical function, as follows: let $D \in D(x, x)$ be Maslov index two positive domain which corresponds to the horizontal annulus $H_i$; then, $D$ can be decomposed as a sum of two rectangles in a unique way, and define the horizontal function $h_{s,x}(i)$ as the product of the signs of the two rectangles. The vertical function $v_{s,x}(i)$ is constructed similarly by considering the vertical annulus $V_i$ instead. Clearly, the horizontal and the vertical functions depend only on the gauge equivalence class of the sign assignment. The following theorem shows that the functions do not depend on the choice of the generator $x$, and will henceforth be denoted by $h_s$ and $v_s$.

**Theorem 3.4.** For any sign assignment $s$, for any two generators $x, y \in G_H$, and for any $1 \leq i \leq N$, the horizontal and the vertical functions satisfy $h_{s,x}(i) = h_{s,y}(i)$ and $v_{s,x}(i) = v_{s,y}(i)$.

**Proof.** Fix a sign assignment $s$, and fix $i \in \{1, \ldots, N\}$. We will only prove the statement for the vertical function; the argument for the horizontal function is very similar. Given $z \in G_H$, let $(z', R_z, R'_z) \in G_H$ be the unique triple with $z' \in G_H$, $R_z \in R(z, z')$ and $R'_z \in R(z', z)$ such that $R_z + R'_z \in D(z, z')$ comes from the vertical annulus $V_i$. We simply want to show that for any two generators $x, y \in G_H$,
enough to prove the above statement when Hasse diagram, when viewed as an unoriented graph, is connected; therefore, it is 
exists a rectangle $R$. In this case, there exists a rectangle $R$. The equality $s(R_x) s(R'_x) = s(R_y) s(R'_y)$ follows trivially.

The generators $y$ and $x'$ disagree on exactly three or exactly four coordinates. In this case, there exists a rectangle $R' \in R(x', y')$, such that $R_x + R' = R + R_y \in D(x, y')$ and $R_x' + R = R' + R_y' \in D(x', y)$. The three essentially different types of diagrams that might appear (up to a rotation by 180°) are illustrated in Figure 3.1. Therefore, $s(R_x) s(R'_x) = -s(R) s(R_y) + s(R'_x) s(R) = -s(R') s(R'_y)$. Multiplying, we get the required identity $s(R_x) s(R'_x) = s(R_y) s(R'_y)$.

The following two theorems will establish that there are exactly $2^{2N-1}$ gauge equivalence classes of sign assignments. Let $\Phi$ be the map from the set of gauge equivalence classes of sign assignments to $\{-1, 1\}^{2N-1}$ given by $s \to (h_s(1), \ldots, h_s(N), v_s(1), \ldots, v_s(N-1))$.

**Theorem 3.5.** Given functions $g_h, g_v : \{1, \ldots, N\} \to \{-1, 1\}$, such that $|g_v^{-1}(1)| \equiv |g_h^{-1}(-1)| \pmod{2}$, there exists a sign assignment $s$, such that $g_h = h_s$ and $g_v = v_s$. Therefore, in particular, the function $\Phi$ from the set of gauge equivalence classes of sign assignments to $\{-1, 1\}^{2N-1}$ is surjective.

**Proof.** By [4, Theorem 4.2], there exists a sign assignment $s_0$ such that $h_{s_0}(i) = 1$ and $v_{s_0}(i) = -1$ for all $i \in \{1, \ldots, N\}$. Given $g_h, g_v : \{1, \ldots, N\} \to \{-1, 1\}$ with $|g_v^{-1}(1)| \equiv |g_h^{-1}(-1)| \pmod{2}$, we would like to modify $s_0$ to get $s$, such that $g_h = h_s$ and $g_v = v_s$. 

![Figure 3.1. The case when $y$ and $x'$ disagree in exactly 3 or exactly 4 coordinates. The coordinates of $x$, $y$, $x'$ and $y'$ are denoted by white circles, black circles, white squares and black squares, respectively.](image-url)
The general method that we employ to modify a sign assignment \( s_1 \) to get another sign assignment \( s_2 \), is the following: we start with a multiplicative 2-cochain \( m \) which assigns elements of \( \{-1, 1\} \) to the elementary domains; if \( D \) is a 2-chain generated by the elementary domains, then \( (m, D) \) is simply the evaluation of \( m \) on \( D \); then, for a rectangle \( R \in \mathcal{R}(x, y) \), we define \( s_2(R) \) to be \( s_1(R) \setminus (m, R) \). It is easy to see that \( s_2 \) is a sign assignment if and only if \( s_1 \) is a sign assignment.

We prove the statement by an induction on the number \( n(g_v, g_h) = \frac{1}{2}(|g_v^{-1}(1)| + |g_h^{-1}(-1)|) \). For the base case, when \( n(g_v, g_h) = 0 \), we can simply choose \( s = s_0 \).

Assuming that the induction hypothesis is proved for \( n = k \), let \( g_v, g_h : \{1, \ldots, N\} \to \{-1, 1\} \) be functions with \( n(g_v, g_h) = k + 1 \). Choose functions \( \tilde{g}_h, \tilde{g}_v : \{1, \ldots, N\} \to \{-1, 1\} \) such that \( n(\tilde{g}_v, \tilde{g}_h) = k \) and \( |\{i \mid g_v(i) \neq \tilde{g}_v(i)\}| + |\{i \mid g_h(i) \neq \tilde{g}_h(i)\}| = 2 \). By induction, there is a sign assignment \( \tilde{s} \) such that \( g_v = h_{\tilde{s}} \) and \( g_h = v_{\tilde{s}} \). If \( |\{i \mid g_v(i) \neq \tilde{g}_v(i)\}| = 2 \), consider the two vertical annuli corresponding to the two values where \( g_v \) disagrees with \( \tilde{g}_v \), choose a horizontal annulus, and let \( m \) be the 2-cochain which assigns \(-1\) to the two elementary domains where the horizontal annulus intersects the two vertical annuli, and 1 to every other elementary domain. Similarly, if \( |\{i \mid g_v(i) \neq \tilde{g}_v(i)\}| = 2 \), consider the two horizontal annuli corresponding to the two values where \( g_h \) disagrees with \( \tilde{g}_h \), choose a vertical annulus, and let \( m \) be the 2-cochain which assigns \(-1\) to the two elementary domains where the vertical annulus intersects the two horizontal annuli, and 1 to every other elementary domain. Finally, if \( |\{i \mid g_v \neq \tilde{g}_v(i)\}| = |\{i \mid g_h \neq \tilde{g}_h(i)\}| = 1 \), consider the vertical annulus corresponding to the value where \( g_v \) disagrees with \( \tilde{g}_v \), consider the horizontal annulus corresponding to the value where \( g_h \) disagrees with \( \tilde{g}_h \), and let \( m \) be the 2-cochain which assigns \(-1\) to the elementary domain where the vertical annulus intersects the horizontal annulus, and 1 to every other elementary domain. Let \( s \) be the sign assignment obtained from \( \tilde{s} \) by modifying it by the 2-cochain \( m \). It is fairly straightforward to check that \( g_h = h_s \) and \( g_v = v_s \).

\( \square \)

**Theorem 3.6.** The function \( \Phi \) from the set of gauge equivalence classes of sign assignments to \( \{-1, 1\}^{2N-1} \) is injective.

**Proof.** For this proof, we will closely follow the corresponding proof from [1]. However, that proof uses the permutahedron whose 1-skeleton is the Cayley graph of the the symmetric group, where the generators are the adjacent transpositions. In our proof, we will use a different simplicial complex, which is the order complex of the partial order \( < \) on \( \mathcal{G}_H \).

Recall that the poset has a unique minimum \( p \) and a unique maximum \( q \). View the Hasse diagram of the poset as an oriented graph \( g \). Choose a maximal tree \( t \) with \( p \) as a root, i.e. given any vertex \( x \), there is a (unique) oriented path from \( p \) to \( x \) in \( t \). The edges of \( g \) correspond to the rectangles that are supported in \([0, N - 1] \times [0, N - 1]\). A sign assignment endows the edges of \( g \) with signs \( \pm 1 \).

Let us choose a \((2N - 1)\)-tuple in \( \{-1, 1\}^{2N-1} \), and let \( s \) be a sign assignment such that the \((2N - 1)\)-tuple equals \( \Phi(s) \). We would like to show that the gauge equivalence class of \( s \) is determined. Since \( t \) is a tree, by replacing the sign assignment \( s \) by a gauge equivalent one if necessary, we can assume that \( s \) labels all the edges of \( t \) with 1’s. We will show that the values of \( s \) on all the other edges are now determined.

Now consider any other edge \( y \leftrightarrow x \) in \( g \). Let \( c_1 \) be the unique oriented path from \( p \) to \( x \) in \( t \), and let \( c_2 \) be the unique oriented path from \( p \) to \( y \) in \( t \). Choose an
Figure 3.2. The induction step. The coordinates of $x$, $y$, $y'$ and $z$ are denoted by white circles, white squares, black squares and black circles, respectively.
depends only on the weak equivalence class of the sign assignment $f$. The following observation yields a direct proof that the chain complex $\hat{v}$

Since $\Phi(N)$, by Theorem 3.5, there exists a sign assignment $s$ such that $s(R_1) \sim R'$. However, $s(R)s(R_1) = -s(R')s(R_1')$, and this determines the sign $s(R)$. This completes the induction and shows that the value of the sign assignment $s$ is fixed on all the rectangles that are supported in $S'$. A similar argument, but with the diagrams rotated by 90°, shows that the value of $s$ is, in fact, determined on all the rectangles. This completes the proof of uniqueness.

Lemma 3.7. For any sign assignment $s$, the product $\prod_{i=1}^{N} h_s(i)v_s(i)$ equals $(-1)^N$.

Proof. By Theorem 3.6 there exists a sign assignment $s'$ such that $h_{s'} = h_s$, $v_{s'}(i) = v_s(i)$ for $i \in \{1, \ldots, N-1\}$ and $v_{s'}(N) = (-1)^N h_s(N) \prod_{i=1}^{N-1} h_s(i)v_s(i)$. Since $\Phi(s) = \Phi(s')$, by Theorem 3.6 $s$ and $s'$ are gauge equivalent. Therefore, $\prod_{i=1}^{N} h_s(i)v_s(i) = \prod_{i=1}^{N} h_{s'}(i)v_{s'}(i) = (-1)^N$.

Fix a sign assignment $s$ and fix a link component $L_i$. Let $V(L_i) = \{j \mid \text{the X marking in } V_j \text{ is in } L_i\}$ and $H(L_i) = \{j \mid \text{the X marking in } H_j \text{ is in } L_i\}$. The product $\langle \prod_{j \in H(L_i)} h_s(j) \rangle = \langle \prod_{j \in V(L_i)} (-v_s(j)) \rangle$ is defined to be the sign of the link component $L_i$ and is denoted by $r_s(L_i)$.

Call two sign assignments $s_1$ and $s_2$ weakly equivalent if $r_{s_1}$ agrees with $r_{s_2}$ on each of the link components. Clearly, if two sign assignments are gauge equivalent, then they are weakly equivalent. Due to Lemma 3.7, the product of the signs of all the link components is 1, and this is the only restriction on these numbers $r_s(L_i)$. Therefore, there are exactly $2^{d-1}$ weak equivalence classes of sign assignments. The following observation yields a direct proof that the chain complex $\text{CFL}_\mathcal{H}(L, \mathbb{Z}, \sigma)$ depends only on the weak equivalence class of the sign assignment $f(\sigma)$.

Lemma 3.8. If two sign assignments $s_1$ and $s_2$ are weakly equivalent, then there exists a sign assignment $s'_2$, which is gauge equivalent to $s_2$, such that $s_1$ and $s'_2$ agree on all the rectangles that avoid the X markings and the O markings.

Proof. Since $s_1$ and $s_2$ are weakly equivalent, a proof similar to the proof of Theorem 3.6 shows that there exists a 2-cochain $m$ which assigns 1 to every elementary domain that does not contain any X or O markings, such that the sign assignment $s'_2$ obtained by modifying $s_1$ by the 2-cochain $m$ satisfies $h_{s_2} = h_{s'_2}$ and $v_{s_2} = v_{s'_2}$. Therefore, by Theorem 3.6, $s'_2$ is gauge equivalent to $s_2$.

Theorem 3.9. The map $f$ from the set of orientation systems to the set of sign assignments induces a well-defined bijection $\tilde{f}$ from the set of weak equivalence classes of orientation systems to the set of weak equivalence classes of sign assignments.

Proof. Recall that two orientation systems $\sigma_1$ and $\sigma_2$ are weakly equivalent if and only if, for a fixed generator $x \in \mathcal{G}_\mathcal{H}$, $\sigma_1$ agrees with $\sigma_2$ on all the domains in $D(x, x)$ that correspond to the empty periodic domains of $\mathcal{P}^0_\mathcal{H}$. Therefore, we need to find a basis for the empty periodic domains.

For each $i \in \{1, \ldots, l\}$, let $P_i = \sum_{j \in V(L_i)} V_j - \sum_{j \in H(L_i)} H_j$. These $l$ empty periodic domains generate $\mathcal{P}^0_\mathcal{H}$, and $\sum_{i=1}^{l} P_i = 0$ is the only relation among these domains. Therefore, the domains $P_1, \ldots, P_{l-1}$ freely generate $\mathcal{P}^0_\mathcal{H}$.

If $D \in D(x, x)$ is a domain which corresponds to a vertical annulus $V_i$, then we know from Paragraph 2.6 that $\sigma_1$ agrees with $\sigma_2$ on $D$ if and only if $v_{f(\sigma_1)}(i) = v_{f(\sigma_2)}(i)$.
Figure 3.3. Grid diagrams for the two-component unlink and the Hopf link.

\[ v_{f(\sigma_2)}(i) \]. A similar statement holds for the horizontal annuli. A repeated application of the same principle shows that if \( D \in D(x, x) \) corresponds to the empty periodic domain \( P_i \), then \( \sigma_1 \) agrees with \( \sigma_2 \) on \( D \) if and only if \( r_{f(\sigma_1)}(L_i) = r_{f(\sigma_1)}(L_i) \). Therefore, the orientation systems \( \sigma_1 \) and \( \sigma_2 \) are weakly equivalent if and only if the sign assignments \( f(\sigma_1) \) and \( f(\sigma_2) \) are weakly equivalent. This shows that the map in question is well-defined and injective. As both sets have \( 2^{l-1} \) elements, it is a bijection. \[ \square \]

A consequence of the theorems in this section is the following.

**Theorem 3.10.** There is a bijection \( \tilde{f} \) between the weak equivalence classes of orientation systems and the weak equivalence classes of sign assignments, such that for each of the \( 2^{l-1} \) weak equivalence classes of orientation systems \( \sigma \), the homology of the grid chain complex, evaluated with the sign assignment \( f(\sigma) \), is isomorphic as an absolutely \((l + 1)\)-graded group to \( \hat{HFL}(L, \mathbb{Z}, \sigma) \otimes_i (\otimes_{m_i} Q_{i}) \).

Let us conclude with a couple of examples. The first grid diagram in Figure 3.3 represents the two-component unlink. There are exactly two generators and exactly two rectangles connecting the two generators. One weak equivalence class assigns the same sign to both the rectangles while the other weak equivalence class assigns opposite signs. Therefore, for one weak equivalence class of orientation systems, the homology is \( \mathbb{Z}/2\mathbb{Z} \), while for the other other weak equivalence class of orientation systems, the homology is \( \mathbb{Z} \oplus \mathbb{Z} \).

The second grid diagram in Figure 3.3 represents the Hopf link. There are twenty-four generators and sixteen rectangles. It can be checked by direct computation that the homology is independent of the sign assignment. Therefore, the link Floer homology of the Hopf link is the same for both the weak equivalence classes of orientation systems.
