(Received 6 March 2013; published 19 April 2013)

Analysis of contributions from vectorlike leptonic supermultiplets to the Higgs diphoton decay rate and to the Higgs boson mass is given. Corrections arising from the exchange of the new leptons and their superpartners as well as their mirrors are computed analytically and numerically. We also study the correlation between the enhanced Higgs diphoton rate and the Higgs mass corrections. Specifically, we find two branches in the numerical analysis: on the lower branch the diphoton rate enhancement is flat, while on the upper branch it has a strong correlation with the Higgs mass enhancement. It is seen that a factor of 1.4–1.8 enhancement of the Higgs diphoton rate on the upper branch can be achieved, and a 4–10 GeV positive correction to the Higgs mass can also be obtained simultaneously. The effect of this extra contribution to the Higgs mass is to release the constraint on weak-scale supersymmetry, allowing its scale to be lower than in the theory without extra contributions. The vectorlike supermultiplets also have collider implications which could be testable at the LHC and at the ILC.

I. INTRODUCTION

Recently the ATLAS and CMS collaborations, using the combined 7 and 8 TeV data, found a signal for a boson, with ATLAS finding a signal at 126.0 ± 0.4(stat) ± 0.4(sys) GeV at the 5.0σ level [1] and the CMS finding a signal at 125.3 ± 0.4(stat) ± 0.5(sys) GeV at the 5.0σ level [2]. While the properties of this boson still need to be fully established, there is the general belief that it is indeed the long-sought-after Higgs boson [3–5] of the electroweak theory [6,7]. In the analysis below, we will assume that the observed boson is indeed the Higgs particle that is a remnant of the electroweak symmetry breaking. It is pertinent to observe that the results of the ATLAS and CMS collaborations are remarkably consistent with the predictions of supergravity grand unified models [8–11] with radiative electroweak symmetry breaking (for a review, see Ref. [12]), which predict the Higgs boson mass to lie below around 130 GeV [13–17]. (For a recent review of Higgs and supersymmetry, see Ref. [18].) However, the fact that the Higgs mass lies close to the upper limit of the prediction of the superunification within the Minimal Supersymmetric Standard Model (MSSM) indicates that the loop correction to the Higgs boson mass is rather large, which in turn implies the existence of a high scale of supersymmetry, specifically a high scale for the squarks. However, corrections on the order of a few GeVs from a source external to MSSM can significantly lower the scale of supersymmetry. Here we investigate this possibility by considering an extension of MSSM with vectorlike leptonic supermultiplets. The assumption of additional vectorlike leptonic supermultiplets will not alter the Higgs production cross section and is not strongly constrained by the electroweak data.

Aside from the relative heaviness of the Higgs boson is the issue of any possible deviations of the Higgs boson couplings from the ones predicted in the Standard Model. If a significant deviation from the Standard Model prediction is seen, it would indicate the existence of new physics. However, it would take a considerable amount of luminosity, i.e., as much as 3000 fb−1 at LHC14 to achieve an accuracy of 10%–20% [19] in the determination of the Higgs couplings with fermions and with dibosons. An exception to the above is the diphoton channel, for which the background is remarkably small, and it was the discovery channel for the Higgs boson. Here the current data gives some hint of a possible deviation from the Standard Model prediction. The ATLAS and CMS collaborations give [1,2]

\[
R_{\gamma\gamma} = \frac{\sigma(p p \to h)_{\text{obs}}}{\sigma(p p \to h)_{\text{SM}}} \frac{\Gamma(h \to \gamma\gamma)_{\text{obs}}}{\Gamma(h \to \gamma\gamma)_{\text{SM}}}
\]

\[
= 1.8 \pm 0.5 \text{ (ATLAS)}, \quad 1.6 \pm 0.4 \text{ (CMS)}, \quad (1)
\]

where

\[
\frac{\sigma(p p \to h)_{\text{obs}}}{\sigma(p p \to h)_{\text{SM}}} = 1.4 \pm 0.3 \text{ (ATLAS)},
\]

\[
0.87 \pm 0.23 \text{ (CMS)}. \quad (2)
\]

In the Standard Model, the largest contribution to the \( h \to \gamma\gamma \) mode arises from the \( W^+W^- \) in the loop, and this contribution is partially canceled by the contribution arising from the top quark in the loop. If this observed enhancement is not due to QCD uncertainties [20], one needs
new contributions beyond the Standard Model to increase the diphoton rate. There are many works which have investigated this possibility, and an enhancement of the diphoton rate can be achieved in many ways: from light states with large mixing [21–24], from extra vectorlike leptons [25–31], and through other mechanisms [32–47]. Additional papers where vectorlike fermions have been discussed are Refs. [48–52]. Most of these works are within a nonsupersymmetric framework. However, with a 125 GeV Higgs mass, vacuum stability is a serious problem in most models. Thus, for example, in the Standard Model, vacuum stability up to the Planck scale may not be achievable, since analysis using next-to-next-leading order correction requires that $m_h > 129.4$ GeV for the vacuum to be absolutely stable up to the Planck scale [53] (see, however, Refs. [54,55]). For this reason, we consider supersymmetric models which are less problematic with regard to vacuum stability (see, e.g., Refs. [28,56–58]). Additionally, the supersymmetric theories avoid the well-known fine-tuning problems of nonsupersymmetric theories. An analysis to determine whether a significant diphoton enhancement can be achieved in MSSM was carried out in Refs. [59,60].

In this work, we consider the effects from additional vectorlike leptonic multiplets in loops on both the Higgs diphoton rate and the Higgs mass in a supersymmetric framework. Vectorlike multiplets appear in a variety of grand unified models [61–63], as well as in string and brane models. Higgs mass enhancement via vectorlike supermultiplets has been considered in previous works; see, e.g., Refs. [64–66]. New particles with couplings to the Higgs are constrained by the electroweak precision tests; such constraints have been discussed in Refs. [27–29,67], and the detection of such particles was discussed in Ref. [68]. The outline of the rest of the paper is as follows: In Sec. II, we give a general analysis of the diphoton rate in the Standard Model as well as in supersymmetric extensions. In Sec. III, we discuss the details of the model. In Sec. IV, we give an analysis of the enhancement of the diphoton rate for the model discussed in the previous section. In Sec. V, we give an analysis of the correction to the Higgs boson mass from radiative corrections arising from the exchange of the vectorlike supermultiplets. A numerical analysis of the corrections to the Higgs diphoton rate and to the Higgs boson mass is given in Sec. VI, and conclusions are given in Sec. VII. Further details are given in Appendixes A and B.

II. A GENERAL ANALYSIS OF THE DIPHOTON RATE

We first consider the Standard Model case with the Higgs doublet $H^0 = (H^+, H^0)$. The full decay width of the Higgs $h$ (where $H^0 = (v + h)/\sqrt{2}$ and $v = 246$ GeV) at the one-loop level involving the exchange of spin-1, spin-1/2 and spin-0 particles in the loops is given by

$$\Gamma(h \rightarrow \gamma \gamma) = \frac{\alpha^2 m_h^3}{1024\pi^3} \left| g_{hVV} \frac{m_V^2}{m_{\gamma}^2} Q_V A_1(\tau_V) \right|^2 + \frac{2g_{hff}}{m_f} N_{c,f} Q_f^2 A_1(\tau_f) + \frac{g_{hSS}}{m_S^2} N_{c,S} Q_S^2 A_0(\tau_S) \right|^2, \tag{3}$$

where $V, f, S$ denote vectors, fermions, and scalars; $Q, N$ are their charges and numbers (colors); $A$’s are the loop functions defined in Ref. [69] and given in Appendix A; and $\tau_i = 4m_i^2/m_j^2$. The couplings $g_{hVV}, g_{hff}, g_{hSS}$, etc., are defined by the interaction Lagrangian so that

$$- \mathcal{L}_{\text{int}} = g_{hVV} h V^+ V^- \mu + g_{hff} h f f + g_{hSS} h S S. \tag{4}$$

For the case of the Standard Model, one has $g_{hWW} = g_2 M_W$ and $g_{hff} = g_2 m_f/(2M_W)$, where $g_2$ is the SU(2) gauge coupling. Here it is easily seen that $g_{hWW}/M_W = 2g_{hff}/m_j = 2/v$. In the Standard Model, the largest contribution to the diphoton rate is from the W boson exchange, and this contribution is partially canceled by the contribution from the top quark exchange. Thus, for the Standard Model, Eq. (3) reduces to

$$\Gamma_{\text{SM}}(h \rightarrow \gamma \gamma) = \frac{\alpha^2 m_h^3}{256\pi^3} A_1(\tau_W) + N_c Q_i^2 A_1(\tau_i) \right|^2 \tag{5}$$

where $A_{\text{SM}} \approx -6.49$.

If the masses of the particles running in the loops which give rise to the decay of the Higgs to diphotons are much heavier than the Higgs boson, the decay of $h \rightarrow \gamma \gamma$ is governed by a $h \gamma \gamma$ effective coupling which can be calculated through the photon self-energy corrections [70,71] and reads

$$\mathcal{L}_{h\gamma\gamma} = \frac{\alpha m_h}{16\pi} \left[ \sum_i b_i Q_i^2 \frac{\partial}{\partial v} \log m_i^2(v) \right] F_{\mu\nu} F^{\mu\nu}, \tag{6}$$

where $b_i$ are

$$b_1 = -7 \quad \text{for a vector boson}, \tag{7}$$

$$b_1 = \frac{4}{3} \quad \text{for a Dirac fermion}, \tag{8}$$

$$b_0 = \frac{1}{3} \quad \text{for a charged scalar}. \tag{9}$$

In the large-mass limit, the exact one-loop result of Eq. (3) agrees with Eq. (6). For relative light particles with mass $m$ running in the loop, $b_i$ receive finite mass corrections to the order of $m_i^2/4m^2$. When there are multiple particles carrying the same electric charge circulating in the loops, one can write a more general expression by replacing $\log m_i^2$ with $\log (\det M_i^2)$, where $M_i^2$ is the mass-squared matrix of the particles circulating in the loops.
For MSSM, one has two Higgs doublets:
\[
H_d = \begin{pmatrix} H_d^0 \\ H_d^+ \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{2}} (v_d + \phi_1) \\ \frac{1}{\sqrt{2}} (H_d^+ + \phi_2) \end{pmatrix},
\]
\[
H_u = \begin{pmatrix} H_u^0 \\ H_u^+ \end{pmatrix} = \begin{pmatrix} \frac{1}{\sqrt{2}} (v_u + \phi_1) \\ \frac{1}{\sqrt{2}} (H_u^+ + \phi_2) \end{pmatrix},
\]
where \(v_d\) and \(v_u\) are the vacuum expectation values of \(H_d^0\) and \(H_u^0\). Extension of Eq. (6) to the supersymmetric case is straightforward, and we have
\[
\Gamma_{\text{SUSY}}(h \rightarrow \gamma \gamma) = \frac{\alpha_{\text{em}} m_h^3}{256 \pi^2} \sin(\beta - \alpha) Q^2 \frac{A_1(\tau_w)}{\sin \beta} + \cos \alpha \frac{b_i Q_i^2}{\sin \beta} N_i \frac{A_1(\tau_i)}{2} \sin(\beta - \alpha) Q^2 \frac{A_1(\tau_j)}{2} \sin \alpha \frac{b_j Q_j^2}{\sin \beta} N_j \frac{A_1(\tau_j)}{2} \sin(\beta - \alpha) Q^2 \frac{A_1(\tau_j)}{2} \sin \alpha \frac{b_j Q_j^2}{\sin \beta} N_j \frac{A_1(\tau_j)}{2} (\cos \alpha \frac{\partial}{\partial v_u} \log m_1^2 - \sin \alpha \frac{\partial}{\partial v_d} \log m_2^2) \right)^2,
\]
where \(\alpha\) is the mixing angle between the two CP-even Higgs in the MSSM. Equation (3) is also modified in the supersymmetric case as we identify the lighter CP-even Higgs with the Standard Model Higgs:
\[
H_d = (1, 2, -\frac{1}{2}), \quad H_u = (1, 2, +\frac{1}{2}),
\]
the superpotential for the vectorlike leptonic supermultiplets is given by
\[
W = y LHdE + y'L^cH_uE + M_LLL^c + M_EEE^c + y_1^{(m)} L^cH_dE + y_2^{(m)} L^cH_dE^c,
\]
where \(M_L\) and \(M_E\) are the vectorlike masses. We assume that the extra leptons can decay only through the third-generation particles, and the corresponding couplings \(y_{i,2}^{(m)}\) are assumed to be very small, and they do not have any significant effect on the analysis here. Neglecting these small terms, the fermionic mass matrix now reduces to
\[
M_F = \begin{pmatrix} M_L & \frac{1}{\sqrt{2}} y' v_d \\ \frac{1}{\sqrt{2}} y' v_d & M_E \end{pmatrix},
\]
where the off-diagonal elements are the masses generated by Yukawa interactions while the diagonal elements are the vector masses. The two mass-squared eigenvalues arising from Eq. (16) are given by
\[
m^2_{1,2} = \frac{1}{4} \left[ 2M_L^2 + 2M_E^2 + y^2 v_u^2 + y^2 v_d^2 \pm \sqrt{(2M_L^2 + 2M_E^2 + y^2 v_u^2 + y^2 v_d^2)^2 - 4(2M_L M_E - y y' v_u v_d)^2} \right].
\]
We call the heavier one \( \tau_1 \) and the lighter one \( \tau_2 \). We note that the neutral components of the SU(2) doublet \( L, L^c \) do not play any role in the analysis, as they do not enter into the analysis of the diphoton rate or the Higgs mass enhancement.

### IV. ENHANCEMENT OF THE DIPHOTON DECAY RATE OF THE HIGGS BOSON

Inclusion of the vectorlike supermultiplet affects the diphoton rate. Using Eqs. (5) and (12), the ratio of the decay width of the lighter CP-even Higgs to two photons and the Standard Model prediction can be written as

\[
\frac{\Gamma(h \rightarrow \gamma\gamma)}{\Gamma(h \rightarrow \gamma\gamma)_{\text{SM}}} = \left[ \frac{1}{|A_{\text{SM}}|^2} \right] \sin(\beta - \alpha) Q_{\text{SM}}^2 A_1(\tau_w) + \cos \alpha \sin \beta N_f Q_r^2 A_1(\tau_r) \\
+ \frac{b_1 v}{2} N_f Q_r^2 \cos \alpha \left( \alpha \frac{\partial}{\partial v_u} \log m_2^2 - \sin \alpha \frac{\partial}{\partial v_d} \log m_2^2 \right) \\
+ \frac{b_0 v}{2} N_f Q_r^2 \cos \alpha \left( \alpha \frac{\partial}{\partial v_u} \log m_3^2 - \sin \alpha \frac{\partial}{\partial v_d} \log m_3^2 \right) \right]^2, \quad (18)
\]

where on the second line we have the fermionic contribution from the vectorlike fermions, and on the third line the scalar contribution from the superpartners of the vectorlike fermions. In the analysis here, we focus only on the extra contributions arising from the exchange of the leptonic vectorlike sector, and do not include other possible corrections to the diphoton rate, such as from the exchange of staus, charginos, and charged Higgs in the loops.

The computation of the vectorlike fermion contribution is straightforward, and we find

\[
\sum_i \left[ \cos \alpha \frac{\partial}{\partial v_u} \log m_i^2 - \sin \alpha \frac{\partial}{\partial v_d} \log m_i^2 \right] = -\frac{v_y v}{m_1 m_2} \cos(\alpha + \beta), \quad (19)
\]

where

\[
m_1 m_2 = M_L M_E - \frac{y y'}{2} v_u v_d. \quad (20)
\]

For the case when \( M_L = M_E = 0 \), the fermionic contribution to the diphoton rate is negative. However, for the case when \( M_L, M_E \neq 0 \), the fermionic contribution can turn positive when \( M_L M_E > \frac{1}{2} y y' v_u v_d \). If the contribution is only from the vectorlike fermions, the Higgs diphoton rate is enhanced by a factor of

\[
\frac{\Gamma(h \rightarrow \gamma\gamma)}{\Gamma(h \rightarrow \gamma\gamma)_{\text{SM}}} = \left[ 1 + \frac{1}{A_{\text{SM}}} b_1 N_f Q_r^2 \frac{v^2 y y'}{2 m_1 m_2} \cos(\alpha + \beta) \right]^2 \\
= \left[ 1 + 0.1 N_f \frac{v^2 y y'}{m_1 m_2} \cos(\alpha + \beta) \right]^2 \\
= \left| 1 + r_f \right|^2, \quad (21)
\]

To determine the contribution from the four superpartner fields of the vectorlike fermions, one needs to find the mass eigenvalues of a \( 4 \times 4 \) mass mixing matrix. In the basis \( \tilde{\tau}_L, \tilde{\tau}_R, \tilde{\tau}_L^c, \tilde{\tau}_R^c \), it is given by

\[
\begin{pmatrix}
y y' v_u M_L + y v_d M_E & 0 \\
0 & y y' v_d M_E + y v_u M_L
\end{pmatrix}
\sqrt{2(M_{\tilde{\tau}}^2)_{2\times2}}
\begin{pmatrix}
y y' v_u M_L + y v_d M_E & 0 \\
0 & y y' v_d M_E + y v_u M_L
\end{pmatrix}
\sqrt{2(M_{\tilde{\tau}}^2)_{2\times2}}
\begin{pmatrix}
y y' v_u M_L + y v_d M_E & 0 \\
0 & y y' v_d M_E + y v_u M_L
\end{pmatrix}
\end{pmatrix}, \quad (22)
\]

where \( (M_{\tilde{\tau}}^2)_{2\times2} \) is given by

\[
(M_{\tilde{\tau}}^2)_{2\times2} = \begin{pmatrix}
M_1^2 + \frac{1}{2} y^2 v_u^2 + M_2^2 + \frac{(x_1 - x_2)}{8} (v_u^2 - v_u^2) & \frac{1}{\sqrt{2}} y (A_{\tau_r} v_d - \mu v_u) \\
\frac{1}{\sqrt{2}} y (A_{\tau_r} v_d - \mu v_u) & M_1^2 + \frac{1}{2} y^2 v_d^2 + M_2^2 - \frac{(x_1 - x_2)}{8} (v_u^2 - v_u^2)
\end{pmatrix}
\]

and \( (M_{\tilde{\tau}^c}^2)_{2\times2} \) is given by

\[
(M_{\tilde{\tau}^c}^2)_{2\times2} = \begin{pmatrix}
M_1^2 + \frac{1}{2} y^2 v_u^2 + M_2^2 - \frac{(x_1 - x_2)}{8} (v_u^2 - v_u^2) & \frac{1}{\sqrt{2}} y (A_{\tau_r} v_u - \mu v_d) \\
\frac{1}{\sqrt{2}} y (A_{\tau_r} v_u - \mu v_d) & M_1^2 + \frac{1}{2} y^2 v_d^2 + M_2^2 + \frac{(x_1 - x_2)}{8} (v_u^2 - v_u^2)
\end{pmatrix}
\]

\[075018-4\]
where $M_1$, $M_2$ are soft scalar masses. For further convenience, we define $M^2 = M_1^2$ and $M'^2 = M_2^2$. As an approximation, we consider the case when the squared soft masses ($M_{i,k}^2$) are much larger than the squared vector masses ($M_{i,k}^2$). In this case, the $4 \times 4$ matrix becomes approximately block diagonal with the diagonal elements consisting of two $2 \times 2$ matrices. As the two mass-squared matrices are decoupled, we denote the superpartners of $\tau'$ to be $\tilde{\tau}'_{1,2}$ and the superpartners of $\tau''$ to be $\tilde{\tau}''_{1,2}$. The contributions from the two decoupled matrices can be obtained straightforwardly. The total bosonic contribution can be measured by $r_b$, which reads

$$r_b = r_1 + r_2 = \frac{1}{\mathcal{A}_{\text{SM}}} \frac{b_0 v}{2} Q_3^2 (\Xi_1 + \Xi_2),$$

where we define

$$\Xi_1 = \cos \alpha \frac{\partial}{\partial v_u} \log (\det M^2) - \sin \alpha \frac{\partial}{\partial v_d} \log (\det M^2),$$

$$\Xi_2 = \cos \alpha \frac{\partial}{\partial v_u} \log (\det M'^2) - \sin \alpha \frac{\partial}{\partial v_d} \log (\det M'^2).$$

We first focus on $\Xi_1$. Using the $\tilde{\tau}'$ mass-squared matrix, a direct computation gives

$$\Xi_1 = \frac{1}{m_{\tilde{\tau}'_1}^2 m_{\tilde{\tau}'_2}^2} \left\{ \left[ -\frac{1}{2} g_1^2 M_{11}' - \frac{(g_1^2 - g_2^2)}{4} M_{22}' \right] v \sin (\alpha + \beta) + \sqrt{2} M_{12}' y (A_{\tilde{\tau}'_1} \sin \alpha + \mu \cos \alpha) \right\}.$$

For the computation of $\Xi_2$, we need the $\tilde{\tau}''$ mass-squared matrix, and a similar analysis gives

$$\Xi_2 = \frac{1}{m_{\tilde{\tau}''_1}^2 m_{\tilde{\tau}''_2}^2} \left\{ \left[ -\frac{1}{2} g_1^2 M_{11}'' + \frac{(g_1^2 - g_2^2)}{4} M_{22}'' \right] v \sin (\alpha + \beta) - \sqrt{2} M_{12}'' y (A_{\tilde{\tau}''_1} \cos \alpha + \mu \sin \alpha) \right\}.$$

Thus, the total Higgs diphoton decay rate is enhanced by a factor

$$R_{\gamma\gamma} = |1 + r_{\tilde{\tau}'} + r_b|^2.$$ 

A numerical analysis of the size of the diphoton rate enhancement using the result of this section is discussed in Sec. VI. For the numerical analysis, we made the same approximation as above; i.e., we choose the value of the squared soft mass to be much larger than the value of the squared vector mass.

V. HIGGS MASS ENHANCEMENT

Extra particles beyond those in MSSM can make contributions to the mass of the Higgs boson. In our case, contributions arise from the exchange of both bosonic and fermionic particles in the vectorlike supermultiplets. The techniques for the computation of these corrections are well known (see, e.g., Refs. [74,75]) and are described in Appendix B. Effectively, the corrections are encoded in elements $\Delta_{ij}$, which are corrections to the elements of a tree-level mass-squared matrix, as defined also in Appendix B. The correction to the lighter CP-even Higgs mass is then given by

$$(\Delta m_h)_F = (2m_h^0)^{-1} (\Delta_{11} \sin^2 \alpha + \Delta_{22} \cos^2 \alpha - \Delta_{12} \sin 2\alpha),$$

where $\alpha$ is the mixing angle between the two CP-even Higgs in the MSSM. Thus, one can write the Higgs boson mass in the form

$$m_h = m_h^{\text{MSSM}} + (\Delta m_h)_F,$$

where $m_h^{\text{MSSM}}$ is the Higgs boson mass in the MSSM and $(\Delta m_h)_F$ is the correction from the new sector given by Eq. (31). In the following, we will discuss the contribution to the lightest Higgs boson mass first from the bosonic sector, and then from the fermionic sector of the vectorlike supermultiplets. The total contribution to the Higgs mass is the sum of bosonic and fermionic contributions, and we have

$$\Delta_{ij} = \Delta_{ij}^b + \Delta_{ij}^f.$$ 

We note that the coupling between the $\tau'$ and the $\tau''$ sectors is characterized by $M_L$ and $M_F$. For the case when $M_L = M_F = 0$, the $\tau'$ and the $\tau''$ sectors (both bosonic and fermionic sectors) totally decouple. In this circumstance, one can calculate $\Delta_{ij}$ analytically.

A. Higgs mass correction from the bosonic sector

The mass-squared matrix in the bosonic sector is given by Eqs. (22)–(24). Here again, we choose the squared soft mass to be much larger than $M_{1,2}^2$. In this circumstance, the $4 \times 4$ mass-squared matrix of Eq. (22) becomes approximately block diagonal, and one can obtain the results for Higgs mass enhancement from the superpartners of the vectorlike fermions ($\tilde{\tau}'_{1,2}$ and $\tilde{\tau}''_{1,2}$). We first compute the corrections from $\tilde{\tau}'_{1,2}$. The computation of the corrections uses the Coleman-Weinberg one-loop effective potential [76,77] (see Appendix B). The contribution to this one-loop effective potential from $\tilde{\tau}'_{1,2}$ exchanges is given by

$$\Delta V^b = \frac{1}{64 \pi^2} \sum_{i=1,2} 2 m_{\tilde{\tau}'_i} \left( \ln \frac{m_{\tilde{\tau}'_i}^2}{Q^2} - \frac{3}{2} \right).$$

where $Q$ is the running renormalization group scale. Our computation of $\Delta_{ij}^b$, following the prescription in Appendix B (further details can be found in Refs. [74,75]), gives
\[ \Delta^\text{eff}_{11} = \beta y^2 v_d^2 \ln \frac{m_{\tilde{\tau}_1}^2 m_{\tilde{\tau}_2}^2}{Q^2} \]

\[ - \beta y^2 v_d^2 A_{\tilde{\tau}_1}^2 \frac{(A_{\tilde{\tau}_1} - \mu \tan \beta)^2}{(m_{\tilde{\tau}_1}^2 - m_{\tilde{\tau}_2}^2)^2} f(m_{\tilde{\tau}_1}^2, m_{\tilde{\tau}_2}^2) \]

\[ + 2\beta y^2 v_d^2 \mu A_{\tilde{\tau}_1} - \mu \tan \beta \ln \frac{m_{\tilde{\tau}_1}^2}{m_{\tilde{\tau}_2}^2} \]

\[ \Delta^\text{eff}_{22} = -\beta y^2 v_d^2 \mu^2 \frac{(A_{\tilde{\tau}_1} - \mu \tan \beta)^2}{(m_{\tilde{\tau}_1}^2 - m_{\tilde{\tau}_2}^2)^2} f(m_{\tilde{\tau}_1}^2, m_{\tilde{\tau}_2}^2) \]

\[ \Delta^\text{eff}_{12} = \beta y^2 v_d^2 \mu A_{\tilde{\tau}_1}^2 \frac{(A_{\tilde{\tau}_1} - \mu \cot \beta)^2}{(m_{\tilde{\tau}_1}^2 - m_{\tilde{\tau}_2}^2)^2} f(m_{\tilde{\tau}_1}^2, m_{\tilde{\tau}_2}^2) \]

\[ - \beta y^2 v_d^2 \mu A_{\tilde{\tau}_1} - \mu \cot \beta \ln \frac{m_{\tilde{\tau}_1}^2}{m_{\tilde{\tau}_2}^2} \]

where \( \beta = 1/16\pi^2 \), and \( f(x, y) \) is given by

\[ f(x, y) = -2 + \frac{y + x}{y - x} \ln \frac{y}{x}. \]

The contribution to the one-loop effective potential from \( \tilde{\tau}_{1,2} \) exchanges is given by

\[ \Delta V^b_{\tilde{\tau}_{1,2}} = \frac{1}{64\pi^2} \sum_{i=1,2} 2m_{\tilde{\tau}_i}^4 \left( \ln \frac{m_{\tilde{\tau}_i}^2}{Q^2} - \frac{3}{2} \right) \]

A similar computation gives the result for \( \Delta^\nu_{\tilde{\tau}_{1,2}} \):

\[ \Delta^\nu_{\tilde{\tau}_{1,2}} = -\beta y^2 v_d^2 \mu^2 \frac{(A_{\tilde{\tau}_1} - \mu \cot \beta)^2}{(m_{\tilde{\tau}_1}^2 - m_{\tilde{\tau}_2}^2)^2} f(m_{\tilde{\tau}_1}^2, m_{\tilde{\tau}_2}^2) \]

\[ + 2\beta y^2 v_d^2 \mu A_{\tilde{\tau}_1} - \mu \cot \beta \ln \frac{m_{\tilde{\tau}_1}^2}{m_{\tilde{\tau}_2}^2} \]

\[ \Delta^\nu_{\tilde{\tau}_{1,2}} = -\beta y^2 v_d^2 \mu^2 \frac{(A_{\tilde{\tau}_1} - \mu \cot \beta)^2}{(m_{\tilde{\tau}_1}^2 - m_{\tilde{\tau}_2}^2)^2} f(m_{\tilde{\tau}_1}^2, m_{\tilde{\tau}_2}^2) \]

\[ + \beta y^2 v_d^2 \mu A_{\tilde{\tau}_1} - \mu \cot \beta \ln \frac{m_{\tilde{\tau}_1}^2}{m_{\tilde{\tau}_2}^2} \]

The contribution to the fermionic sector from the Higgs boson mass is given by

\[ \Delta V^f_{\tilde{\tau}_{1,2}} = -\frac{1}{64\pi^2} \sum_{i=1,2} 2m_i^4 \left( \ln \frac{m_i^2}{Q^2} - \frac{3}{2} \right) \]

where \( m_{1,2} \) are the mass eigenvalues of the vectorlike fermions which are given in Eq. (17). A straightforward analysis gives

\[ \Delta_{11} = -\beta \left[ \left( \frac{1}{2} y^2 v_d^2 - \frac{1}{2} N_1 \sqrt{R} + \frac{R_d^2}{8R} \right) \ln \frac{m_i^2 m_j^2}{Q^2} \right. \]

\[ + \left. \left( \frac{y^2 v_d R_d^0}{2\sqrt{R}} - \frac{1}{2} N_1 T \right) \ln \frac{m_i^2}{m_j^2} + N_1 \sqrt{R} \right]. \]

\[ \Delta_{22} = -\beta \left[ \left( \frac{1}{2} y^2 v_d^2 - \frac{1}{2} N_2 \sqrt{R} + \frac{R_u^2}{8R} \right) \ln \frac{m_i^2 m_j^2}{Q^2} \right. \]

\[ + \left. \left( \frac{y^2 v_d R_u^0}{2\sqrt{R}} - \frac{1}{2} N_2 T \right) \ln \frac{m_i^2}{m_j^2} + N_2 \sqrt{R} \right]. \]

\[ \Delta_{12} = -\beta \left[ \left( \frac{1}{2} y^2 y^2 v_u v_d - \frac{1}{2} N_1 \sqrt{R} + \frac{R_u^2 R_d^0}{4\sqrt{R}} \right) \ln \frac{m_i^2 m_j^2}{Q^2} \right. \]

\[ + \left. \left( \frac{y^2 v_u R_u^0}{4\sqrt{R}} + \frac{y^2 v_d R_d^0}{4\sqrt{R}} - \frac{1}{2} N T \right) \ln \frac{m_i^2}{m_j^2} + N \sqrt{R} \right], \]
experimental lower limits \cite{78}. Masses of the new particles must be consistent with the distribution given by Eqs. (45)–(47). In this section, for the exchange of the vectorlike supermultiplets is decoupled, and we label the two sectors as the \( \tilde{v} \) and \( \tilde{v}' \) sectors, where \( \tilde{v} \) denotes contributions from both \( v \) and its super-partners \( \tilde{v}' \), and similar for \( \tilde{v}' \). Here we choose the following parameters: \( M_1 = M_2 = 500 \text{ GeV} \), \( \mu = 1 \text{ TeV} \), \( \tan \beta = 1.4 \), \( \alpha = \beta - \pi/2 \), \( y = y' = 1 \), and \( m_{h}^{\text{MSSM}} = 120 \text{ GeV} \). Using the above parameters and Eq. (21), we find that the fermionic contribution to the Higgs diphoton rate \( r_f \) is roughly \(-0.4\) in this case, which is a large negative effect. However, this is compensated by the contribution from the bosonic sector, and this contribution is displayed in the upper two panels of Fig. 1. The upper-left panel displays the diphoton rate enhancements from the exchange of \( \tilde{v}'_{1,2} \) in the loop vs \( A_{\nu} \), while the upper-right panel displays the diphoton rate enhancement from the exchange of \( \tilde{v}'_{1,2} \) vs \( A_{\nu'} \). As expected, in each case, we find that the contribution from scalar loops enhances the diphoton rate. The total contribution arising from the sum of the fermionic and the bosonic sectors will be given when we discuss Fig. 2.

An analysis of the enhancement of the Higgs boson mass in the decoupled case \( M_L = M_E = 0 \) is given in the lower two panels of Fig. 1. The lower-left panel of Fig. 1 gives a display of the Higgs mass enhancement from the exchange of the \( \tilde{v}' \) sector (including bosonic and fermionic contributions) in the loop vs \( A_{\nu} \). Here the contribution to the Higgs boson mass is rather modest, not exceeding much beyond 2 GeV over the entire range of \( A_{\nu} \). A similar analysis for the mirror sector \( (\tilde{v}''_{1,2}) \) is given in the right panel of Fig. 1, where the Higgs boson mass enhancement is plotted against \( A_{\nu'} \). Here large contributions are seen to arise. We turn now to a display of the combined diphoton rate from the fermionic and the bosonic sectors vs the combined Higgs boson mass enhancement from the fermionic and bosonic sectors. This analysis is presented in the left panel of Fig. 2, where we display the total diphoton rate enhancement \( r_{\gamma\gamma} \) as defined in Eq. (30) vs the total Higgs mass correction (here we chose the maximum value for diphoton rate enhancement from the \( \tilde{v}' \) sector, which corresponds to \( A_{\nu} = 3100 \text{ GeV} \)). While a simultaneous enhancement in both sectors does occur, one finds in this case the sizes are rather modest; e.g., one has a 3–4 GeV enhancement in the Higgs boson mass, with a 30\% enhancement in the diphoton rate at the same time.

Next, we discuss the case when \( M_L, M_E \) are non-vanishing. Here we choose the following parameters: \( M_1 = M_2 = 210 \text{ GeV}, M_1 = M_2 = 600 \text{ GeV}, Q = \mu = 1 \text{ TeV}, \tan \beta = 3, \alpha = \beta - \pi/2, y = y' = 1, \) and \( m_{h}^{\text{MSSM}} = 120 \text{ GeV} \). This time, the contribution to the diphoton rate from the fermionic sector is positive and gives \( r_f = +0.1 \) upon using Eq. (21). The bosonic contribution is exhibited in the upper two panels of Fig. 3, where the upper-left panel displays the contribution from the exchange of \( \tilde{v}'_{1,2} \) in the loop vs \( A_{\nu} \), while the upper-right panel displays the contribution from the exchange of \( \tilde{v}'_{1,2} \) in the loop vs \( A_{\nu'} \). Here essentially all of the bosonic sector enhancement comes from the \( \tilde{v}' \) sector.

In the lower-left panel of Fig. 3, we display the total Higgs mass enhancements (adding up both the bosonic and
fermionic contributions) vs $A_{\nu}$, where we choose $A_{\nu} = 1000$ GeV. Similarly to the diphoton enhancement, the major contribution to the Higgs boson mass enhancement is also from the exchange of $\tilde{\tau}^f_{1,2}$. In the lower-right panel of Fig. 3, we display the total Higgs mass enhancement vs the renormalization group scale $Q$. Again we choose $A_{\nu} = 1000$ GeV, and three specific values for $A_{\nu}$ which correspond to three different values of the Higgs mass enhancement are chosen as shown in the plot. The values for the scale $Q$ cover a large range from 500 GeV to 10 TeV, and we see three almost straight horizontal lines for the Higgs mass enhancement as a function of $Q$. This plot shows that the Higgs mass enhancement has almost no dependence on the scale $Q$, which verifies that our approximation in computing the bosonic contribution to the Higgs mass is valid. Combining the diphoton rate from both the

![Graph](image4.png)

FIG. 2. Left panel: A display of the correlation between the Higgs diphoton rate enhancement and the Higgs mass enhancement in the decoupled limit where $M_L = M_E = 0$, as in Fig. 1. Right panel: A display of the correlation between the Higgs diphoton rate enhancement and the Higgs mass enhancement for the case when the vector masses are nonvanishing where $M_L = M_E = 210$ GeV. The two branches shown in each of the two plots are due to the rise and fall of the Higgs mass enhancement, as exhibited in the lower panels of Figs. 1 and 3.
bosonic and the fermionic sectors of the vectorlike supermultiplets, we display in the right panel of Fig. 2 the total diphoton rate enhancement $R_{\gamma\gamma}$ vs the total Higgs mass correction (where again we fix the contribution from $\tilde{\tau}'_{1,2}$, choosing $A_{\tau'} = 1000$ GeV). Here we find that including the vector masses, one can easily achieve a diphoton rate enhancement as well as a Higgs mass enhancement of substantial size. In Fig. 4, we give a display of the slepton masses. Here one finds that the slepton masses from the new sector are typically in the few-hundred GeV range except near the end points, and that they lie substantially above the experimental lower limits [78]. These mass ranges are consistent with the electroweak constraints which have been discussed in a number of works [27,28,50,65–67].

Finally, we comment on the vacuum stability constraints. These constraints on the $\tilde{\tau}$ and $\tilde{\tau}'$ sectors are similar to those discussed for the stau sector of MSSM

FIG. 4. A display of the slepton masses vs the trilinear couplings in the case $M_L = M_E = 210$ GeV. Left panel: A plot of the $\tilde{\tau}'_{1,2}$ masses vs $A_{\tau'}$. Right panel: A plot of $\tilde{\tau}'_{1,2}$ masses vs $A_{\tau'}$. We note that the slepton masses over most of the parameter space lie significantly above the experimental lower limits [78].
and arise from the left-right mixing of the staus [56–58]. The mixings lead to a cubic term in the Higgs potential expanded around the electroweak-symmetry-breaking vacuum which is of type $-y^2 m \tilde{\tau}_L \tilde{\tau}_R^c$ and $-y' m \tilde{\tau}_L^c \tilde{\tau}_R$. Such terms can generate global minima in some cases. The parameter that controls the instability is $\mu \tan \beta$. Without going into details because of the smallness of $\mu \tan \beta$ for the analysis given in Figs. 1–4, the solutions we present are consistent with the vacuum stability constraints.

VII. CONCLUSION

In this work, we consider an extension of MSSM with vectorlike leptonic supermultiplets and its possible implications for the Higgs diphoton rate and the Higgs boson mass. Specifically, we compute one-loop corrections to the diphoton rate of the Higgs boson via the exchange of the new leptons and their superpartners, as well as their mirrors. A similar analysis is carried out for the Higgs boson mass, where we compute corrections to its mass using the renormalization-group-improved Coleman-Weinberg effective potential with contributions arising also from these new particles. It is found that an enhancement of the diphoton rate as large as 1.8 can occur, and simultaneously a positive correction of 4–10 GeV to the Higgs boson mass. Specifically, we compute one-loop corrections to the effective potential with contributions arising also from these new leptons and their superpartners, as well as their mirrors. A correction of this size can have a significant effect in relieving the constraint on the weak-scale supersymmetry.

In the supergravity unified model with universal boundary conditions at the grand unified theory scale, one finds that for a Higgs mass in the 125–126 GeV region, the squark masses are rather heavy (see Fig. 1 of Ref. [13]) and would be difficult to access at the LHC. However, a 5–10 GeV contribution to the Higgs mass from the new sector would put the MSSM component of the Higgs mass in the 116–120 GeV range, which allows a significant lowering of the universal scalar mass (see Fig. 1 of Ref. [13]). Thus, a Higgs mass correction of the size discussed in this work not only gives a significant correction to the diphoton rate but also lowers the scale of supersymmetry, making sparticles more accessible in the next round of experiments at the LHC [79]. We also note that in the right panel of Fig. 4 one finds that one of the scalar mass eigenvalues can lie close to the current experimental lower limit, and thus such states could be accessible at the LHC and at the ILC.

The vectorlike leptons can be produced at the LHC via processes such as $pp \to Z \to \tau^+ \tau^-$. The charged vectorlike leptons will likely decay inside the detector via their gauge interactions, similar to any heavy lepton, e.g., $\tau^+ \to \tau \nu_\tau \bar{\nu}_\tau$, with the subsequent decay of $\nu_\tau$. The decay of $\nu_\tau$ would depend on mixings and is model dependent, but in the end it could produce $l^+ l^- \nu_\tau$. In this case, we have as many as three charged leptons and missing $E_T$.

However, an accurate analysis of the background is needed to quantify the size of the signal, which is outside the scope of this work. Of course, the best chance of seeing these particles would be at the ILC through the process $e^+ e^- \to Z \to \tau^+ \tau^-$ if sufficient center-of-mass energy can be managed.

APPENDIX A: LOOP FUNCTIONS

The loop functions $A_1(x), A_2(x)$, and $A_0(x)$ that appear in Sec. II are defined by

$A_1(\tau) = -[2 + 3\tau + 3\tau(2 - \tau)f(\tau)],$ \hspace{1cm} (A1)

$A_2(\tau) = 2\tau[1 + (1 - \tau)f(\tau)],$ \hspace{1cm} (A2)

$A_0(\tau) = -\tau[1 - \tau f(\tau)].$ \hspace{1cm} (A3)

Here the function $f(\tau)$ is defined by

$f(\tau) = \begin{cases} \left(\arcsin \frac{\eta}{\sqrt{\tau}}\right)^2, & \tau \geq 1, \\ -\frac{1}{4} \left[ \ln \frac{\eta_+ - i\pi}{\eta_-} \right]^2, & \tau < 1, \end{cases}$ \hspace{1cm} (A4)

where $\eta_{\pm} \equiv (1 \pm \sqrt{1 - \tau})$ and $\tau = 4m^2/m_H^2$ for a particle running in the loop with mass $m$. For the case when $\tau \gg 1$, one has

$f(\tau) \to \frac{1}{\tau} \left( 1 + \frac{1}{3\tau} + \frac{3}{20\tau^2} + \cdots \right).$ \hspace{1cm} (A5)

and in this limit $A_1 \to -7, A_2 \to 4/3, A_0 \to 1/3$.

APPENDIX B: LOOP CORRECTIONS TO THE HIGGS BOSON MASS

In this Appendix, we give details of the computation of corrections to the Higgs boson mass-squared matrix arising from radiative corrections to the Higgs boson potential. The Higgs potential is given by

$V(H_u, H_d) = V_0 + \Delta V,$ \hspace{1cm} (B1)

where $V_0$ is the renormalization-group-improved tree-level potential and $\Delta V$ is the loop correction. For the case of two Higgs doublets in MSSM, including soft terms, the Higgs potential $V$ is given by
\[ V_0 = \tilde{m}_{H_u}^2 |H_u|^2 + \tilde{m}_{H_d}^2 |H_d|^2 + (B\mu)^2 H_u H_d + \text{H.c.} \]
\[ + \left( \frac{g_2^2 - g_1^2}{4} |H_u|^2 |H_d|^2 + \frac{g_2^2 + g_1^2}{8} |H_u|^4 \right) \]
\[ + \frac{\tilde{m}_{H_u}^2}{8} |H_d|^4 - \frac{\tilde{m}_{H_d}^2}{2} |H_u H_d|^2, \]  
(B2)

where \( \tilde{m}_{H_u}^2 = M_{H_u}^2 = |\mu|^2, \tilde{m}_{H_d}^2 = M_{H_d}^2 + |\mu|^2, \) and \( M_{H_u}, M_{H_d} \)
and \( B \) are the soft parameters. The correction \( \Delta V \) to the effective potential at the one-loop level is given by [76,77]
\[ \Delta V = \frac{1}{64 \pi^2} \text{Str} \left[ M_J^4(H_u, H_d) \left( \ln \frac{M_J^2(H_u, H_d)}{Q^2} - \frac{3}{2} \right) \right] \]  
(B3)

where \( M_J \) is the mass eigenvalue of the particle being exchanged. \( \text{Str} \) stands for the sum \( \sum_j c_j(2J_j + 1)(-1)^{2J_j} \), \( c_j(2J_j + 1) \) counts the degrees of freedom, and the sum runs over all the particles \( i \) bosonic and fermionic being exchanged in the loop. Thus, to construct the mass-squared matrix of the Higgs scalars, we need to compute the quantity
\[ (M_H)^2_{\alpha\beta} = \frac{\partial^2 V}{\partial v_{\alpha} \partial v_{\beta}} = (M_H^2)^0 + \Delta M_{H\alpha\beta}, \]  
(B4)

where \( (\alpha, \beta) = (1, 2) \) and \( v_1 = v_u, v_2 = v_d, (M_H^2)^0 \) is the contribution from \( V_0 \), and \( \Delta M_{H\alpha\beta} \) is the contribution from \( \Delta V \). \( \Delta M_{H\alpha\beta} \) is given by

\[ M_H^2 = \begin{pmatrix} M_Z^2 c_\beta^2 + M_A^2 s_\beta^2 + \Delta_{11} & -(M_Z^2 + M_A^2) s_\beta c_\beta + \Delta_{12} \\ -(M_Z^2 + M_A^2) s_\beta c_\beta + \Delta_{12} & M_Z^2 s_\beta^2 + M_A^2 c_\beta^2 + \Delta_{22} \end{pmatrix}, \]  
(B8)

where \( M_Z^2 = \frac{1}{4}(g_1^2 + g_2^2)(v_u^2 + v_d^2) \) and \( M_A^2 = -2|B\mu|^2 / \sin(2\beta) + \cdots \), and \( \Delta_{ij} \) are now given by [74,75]
\[ \Delta_{11} = \left( -\frac{1}{v_d} \frac{\partial}{\partial v_d} + \frac{\partial^2}{\partial v_d^2} \right) \Delta V, \]  
(B9)
\[ \Delta_{22} = \left( -\frac{1}{v_u} \frac{\partial}{\partial v_u} + \frac{\partial^2}{\partial v_u^2} \right) \Delta V, \]  
(B10)
\[ \Delta_{12} = \frac{\partial^2}{\partial v_u \partial v_d} \Delta V. \]  
(B11)

Evaluations of \( \Delta_{ij} \) for the vectorlike leptonic supermultiplet are given in Sec. V.
