MULTIPLE FIBERS OF DEL PEZZO FIBRATIONS

SHIGEFUMI MORI AND YURI PROKHOROV

Abstract. We prove that a terminal three-dimensional del Pezzo fibration has no fibers of multiplicity \( \geq 6 \). We also obtain a rough classification possible configurations of singular points on multiple fibers and give some examples.

1. Introduction

Throughout this paper a \textit{weak del Pezzo fibration} is a projective morphism \( f : X \to Z \) with connected fibers from a threefold \( X \) with terminal singularities to a smooth curve \( Z \) such that \( -K_X \) is \( f \)-nef and \( f \)-big near a general fiber. If additionally \( -K_X \) is \( f \)-ample, we say that \( f : X \to Z \) is a \textit{del Pezzo bundle}. (We do not assume that \( X \) is \( \mathbb{Q} \)-factorial nor \( \rho(X/Z) = 1 \)). The main reason to study del Pezzo fibrations comes from the three-dimensional birational geometry, namely the class of del Pezzo bundles with \( \mathbb{Q} \)-factorial singularities and relative Picard number one is one of three possible outcomes of the minimal model program for threefolds of negative Kodaira dimension.

Our main result is the following.

Theorem 1.1. Let \( f : X \to Z \) be a weak del Pezzo fibration and let \( f^*(o) = m_oF_o \) be a special fiber of multiplicity \( m_o \). Then \( m_o \leq 6 \). Moreover, all the cases \( 1 \leq m_o \leq 6 \) occur. Furthermore, let \( B(F_o) = (r_1, \ldots, r_n) \) be the basket of singular points of \( X \) at which \( F_o \) is not Cartier. Then, in the case \( m_o \geq 2 \), there are only the following possibilities:

\begin{enumerate}
  \item \( m_o = 2, B(F_o) = (8), (2, 6), (4, 4), (2, 2, 4), \) or \( (2, 2, 2, 2) \),
  \item \( m_o = 3, B(F_o) = (9), (3, 3, 3), \) or \( (3, 6) \),
  \item \( m_o = 4, B(F_o) = (2, 4, 4), \)
  \item \( m_o = 5, B(F_o) = (5, 5), \)
  \item \( m_o = 6, B(F_o) = (2, 3, 6). \)
\end{enumerate}

The possible types of singularities in \( B(F_o) \), the local behavior of \( F_o \) near singular points, and the possible types of a general fiber are collected in Table 1.

1991 Mathematics Subject Classification. 14J30, 14E35, 14E30.

Warning. In the statement of Theorem 1.1 and Table 1 we do not assert that the basket $B(F_o)$ contains all the singularities along $F_o$. It is possible that $F_o$ is Cartier at some non-Gorenstein points (see Example 5.6).

| type     | $m_o$ | $B(F_o) = (r_1, \ldots, r_n)$ | $(b_1, \ldots, b_n)$ | $q_i$ | $K^2_{F_o}$ |
|----------|-------|-------------------------------|----------------------|-------|-------------|
| $I_{2,3,6}$ | 6    | (2, 3, 6)                   | $(1, \pm 1, \pm 1)$ | $q_i \equiv -1$ | 6           |
| $I_{5,5}$      | 5    | (5, 5)               | $b_1^2 + b_2^2 \equiv 0$ | $q_i \equiv -1$ | 5           |
| $I_{2,4,4}$    | 4    | (2, 4, 4)              | $(1, \pm 1, \pm 1)$ | $q_i \equiv -1$ | 4, 8        |
| $I_{3,3,3}$    | 3    | (3, 3, 3)              | $(\pm 1, \pm 1, \pm 1)$ | $q_i \equiv -1$ | 3, 6, 9     |
| $I_{2,2,2,2}$  | 2    | (2, 2, 2, 2)          | $(1, 1, 1, 1)$ | $q_i \equiv 1$ | even        |
| $I_{3,6}$      | 3    | (3, 6)               | $(\pm 1, \pm 1)$ | $q_i \equiv 4$ | 3, 6, 9     |
| $I_9$         | 3    | (9)                     | $b_1 = \pm 2q_1/3$ | $q_1 = 3$ or $6 \equiv q_1/3$ mod 3 |
| $I_{2,2,4}$    | 2    | (2, 2, 4)              | $(1, 1, \pm 1)$ | $q_i \equiv r_i/2$ | odd        |
| $I_{4,4}$      | 2    | (4, 4)               | $(\pm 1, \pm 1)$ | $q_i \equiv r_i/2$ | even       |
| $I_{2,6}$      | 2    | (2, 6)               | $(1, \pm 1)$ | $q_i \equiv r_i/2$ | even       |
| $I_8$         | 2    | (8)                     | $(\pm 1)$ or $(\pm 3)$ | $q_i \equiv r_i/2$ | odd        |

The idea of the proof is easy. In fact, it is sufficient to compute dimensions of linear systems $\dim|lF_o|$ by using the orbifold Riemann-Roch formula [Rei87]. The main theorem is proved in §§3–4. In §5 we give some examples. In fact, it will be shown that all cases in Table 1 except possibly for cases $I_{2,6}$ and $I_8$ occur. Finally, in §6 we discuss fibers of multiplicity 5 and 6.

Notation in Table 1. The number $b_k$ in the fourth column is the weight which appears in a singularity $\frac{1}{r_k}(1, -1, b_k) \in B(F_o)$, $q_k$ in the fifth column is an integer such that $F_o \sim q_k K_X$ near $P_k \in B(F_o)$. $F_g$ in the final column denotes a general fiber of $f$. We say that the fiber $f^*(o) = m_o F_o$ is of type $I_{r_1, \ldots, r_n}$ if $B(F_o) = (r_1, \ldots, r_n)$.

We also say that the fiber $F_o$ is regular if it is of type $I_{2,3,6}$, $I_{5,5}$, $I_{2,4,4}$, $I_{3,3,3}$, or $I_{2,2,2,2}$. Otherwise, $F_o$ is said to be irregular.
Acknowledgments. Much of this work was done at the Research Institute for Mathematical Sciences (RIMS), Kyoto University in February 2008. The second author would like to thank RIMS for invitation to work there, for hospitality and stimulating working environment.

2. Preliminaries

2.1. Terminal singularities [Mor85], [Rei87]. Let \((X, P)\) be a three-dimensional terminal singularity of index \(r\) and let \(D\) be a Weil \(\mathbb{Q}\)-Cartier divisor on \(X\).

Lemma 2.2 ([Kaw88, Corollary 5.2]). In the above notation, there is an integer \(i\) such that \(D \sim iK_X\) near \(P\). In particular, \(rD\) is Cartier.

2.3. Notation as above. There is a deformation \(X_{\lambda}\) of \(X\) such that \(X_{\lambda}\) has only cyclic quotient singularities \((X_{\lambda}, P_{\lambda,k}) \cong \frac{1}{r_k}(1, -1, b_k), 0 < b_k < r_k, \gcd(b_k, r_k) = 1\). Thus, to every threefold \(X\) with terminal singularities, one can associate a collection \(B = ((r_{P,k}, b_{P,k})), P_{\lambda,k} \in X_{\lambda,k}\) is a singularity of type \(\frac{1}{r_{P,k}}(1, -1, b_{P,k})\). This collection is called the basket of singularities of \(X\). By abuse of notation, we also will write \(B = (r_{P,k})\) instead of \(B = ((r_{P,k}, b_{P,k})).\) The index of \((X, P)\) is the least common multiple of indices of points \(P_{\lambda,k}\.\) For any Weil divisor \(D\), \(B(D) \subset B\) denotes the collection of points where \(D\) is not Cartier.

Deforming \(D\) with \((X, P)\) we obtain Weil divisors \(D_{\lambda}\) on \(X_{\lambda}\). Thus we have a collection of numbers \(q_k\) such that \(0 \leq q_k < r_k\) and \(D_{\lambda} \sim q_kK_{X_{\lambda}}\) near \(P_{\lambda,k}\).

2.4. Orbifold Riemann-Roch formula [Rei87]. Let \(X\) be a threefold with terminal singularities and let \(D\) be a Weil \(\mathbb{Q}\)-Cartier divisor on \(X\). Then

\[
\chi(D) = \frac{1}{12} D \cdot (D - K_X) \cdot (2D - K_X) + \frac{1}{12} D \cdot c_2(X) + \chi(\mathcal{O}_X) + \sum_{P \in B} c_p(D),
\]

where

\[
c_p(D) = -q_p \frac{r_p^2 - 1}{12r_p} + \sum_{j=1}^{q_p-1} \frac{b_pj(r_p - b_pj)}{2r_p},
\]

\(q_p\) is such as in 2.3, and \(\overline{\cdot}\) denotes the smallest residue \(\mod r_p\).

Assume that \(D^2 \equiv 0\). Then

\[
\chi(D) = \frac{1}{12} D \cdot K_X^2 + \frac{1}{12} D \cdot c_2(X) + \chi(\mathcal{O}_X) + \sum c_p(D).
\]
We have (see, e. g., [Ale94, proof of 2.13])

\[
(2.8) \quad c_p(-K) = \frac{r_p^2 - 1}{12r_p} - \frac{b_p(r_p - b_p)}{2r_p}, \quad c_p(K) = -\frac{r_p^2 - 1}{12r_p}.
\]

**Construction 2.9** (Base change). Let \( f : X \to Z \) be a weak del Pezzo fibration and let \( f^*(o) = m_oF_o \) be a special fiber of multiplicity \( m_o \). Regard \( f : X \to (Z,o) \) as a germ. Let \((\mathbb{C}, 0) \simeq (Z', o') \to (Z, o) \simeq (\mathbb{C}, 0)\) is given by \( t \mapsto t^{m_o} \) and let \( X' \) be the normalization of \( X \times_Z Z' \). We obtain the following commutative diagram:

\[
\begin{array}{ccc}
X' & \xrightarrow{\pi} & X \\
f' \downarrow & & \downarrow f \\
Z' & \xrightarrow{f} & Z
\end{array}
\]

Here \( f' \) is a weak del Pezzo fibration with special fiber \( F'_o = f'^*o' = \pi^*F_o \) of multiplicity 1 and \( \pi \) is a \( \mu_{m_o} \)-cover which is étale outside of the set \( M \) of points where \( F_o \) is not Cartier. Hence there is a \( \mu_{m_o} \)-action on \( X' \) such that \( X = X'/\mu_{m_o} \) and the action is free outside of \( M \).

Conversely, let \( f' : X' \to Z' \ni o' \) be a weak del Pezzo fibration with central fiber of multiplicity 1. Assume that \( f \) equipped with an equivariant \( \mu_{m_o} \)-action such that the action on \( X' \) is étale in codimension two. If the quotient \( X'/\mu_{m_o} \) has only terminal singularities, then \( X'/\mu_{m_o} \to Z'/\mu_{m_o} \) is a weak del Pezzo fibration with special fiber of multiplicity \( m_o \).

**Proposition 2.11.** Let \( f : X \to Z \) be a weak del Pezzo fibration. Let \( f^*(o) = m_oF_o \) be a special fiber of multiplicity \( m_o \). There is a point \( P \in F_o \) such that the index of \( F_o \) at \( P \) is divisible by \( m_o \).

**Proof.** Regard \( f : X \to (Z,o) \) as a germ and apply Construction 2.9. It is sufficient to show that \( \mu_{m_o} \) has a fixed point on \( F'_o \) (see Lemma 2.2).

First we consider the case of del Pezzo bundle, i.e., the case where \( -K_X \) is ample. Let \( \gamma \) be the log canonical threshold of \((X', F'_o)\) and let \( W' \subset X' \) be a minimal center of log canonical singularities of \((X', \gamma F'_o)\) (see [Kaw97a, §1]).

Assume that \( \dim W' \leq 1 \). Let \( H \) be a general hyperplane section of \( X \) passing through \( \pi(W') \) and let \( H' := \pi^*H \). For \( 0 < \varepsilon \ll 1 \), the pair \((X', \gamma F'_o + \varepsilon H')\) is not LC along \( \pi^{-1}\pi(W') \) and LC outside. Therefore for some \( 0 < \delta \ll \varepsilon \) the pair \((X', (\gamma - \delta)F'_o + \varepsilon H')\) is not KLT along \( \pi^{-1}\pi(W') \) and KLT outside. Moreover, \( W' \) is a minimal LC center for \((X', (\gamma - \delta)F'_o + \varepsilon H')\). Recall that any irreducible component of the intersection of two LC centers is also an LC center [Kaw97a, Proposition 1.5]. Hence \( W' \) is the only LC center in its neighborhood. Since the boundary \((\gamma - \delta)F'_o + \varepsilon H'\) is \( \mu_{m_o} \)-invariant, all the \( gW' \) for \( g \in \mu_{m_o} \) are also centers of log canonical singularities for the pair \((X', (\gamma - \delta)F'_o + \varepsilon H')\). On the other hand, the locus \( \mu_{m_o}W' \) of log
canonical singularities for the pair \((X', (\gamma - \delta)F_o' + \varepsilon H')\) is connected, see [Sho93, §5], [Ko92, 17.4]. Hence \(\mu_{m_o} W'\) is irreducible and so \(W'\) is \(\mu_{m_o}\)-invariant. If \(W'\) is a point, we are done. Otherwise \(W'\) is a smooth rational curve [Kaw97a, Th. 1.6], [Kaw97b]. But any cyclic group acting on \(\mathbb{P}^1\) has a fixed point.

Assume that \(\dim W' = 2\), that is, \(W' = [\gamma F_o']\) and the pair \((X', \gamma F_o')\) is PLT. By the inversion of adjunction [Sho93, 3.3], [Ko92, 17.6] and Connectedness Lemma [Sho93, §5], [Ko92, 17.4] the surface \(W'\) is irreducible, normal and has only KLT singularities. Hence \(W'\) is a KLT log del Pezzo surface. In particular, \(W'\) is rational. Then the assertion follows by Lemma 2.12 below.

Now we consider the general case. We apply \(\mu_{m_o}\)-equivariant MMP in the category \(\mu_{m_o}\)-threefolds (i.e., threefolds with terminal singularities and such that every \(\mu_{m_o}\)-invariant Weil divisor is \(\mathbb{Q}\)-Cartier, see e.g. [Mor88, 0.3.14]). Let \(X_i \rightarrow X'\) be a \(\mu_{m_o}\)-equivariant \(\mathbb{Q}\)-factorialization. Run \(\mu_{m_o}\)-equivariant MMP over \(Z'\):

\[
X_1 \rightarrow X_2 \rightarrow \cdots \rightarrow X_N.
\]

These maps induce a sequence maps

\[
X_1/\mu_{m_o} \rightarrow X_2/\mu_{m_o} \rightarrow \cdots \rightarrow X_N/\mu_{m_o}.
\]

where each step is either \(K\)-negative divisorial contraction or a flip (both are not necessarily extremal). Hence, on each step the quotient \(X_i/\mu_{m_o}\) has only terminal singularities and the action of \(\mu_{m_o}\) on \(X_i\) is free in codimension two. On the last step \(X_N\) is either a del Pezzo bundle over \(Z'\) with \(\rho_{\mu_{m_o}}(X_N/Z') = 1\) or a \(\mathbb{Q}\)-conic bundle over a surface \(S\) and \(S/Z'\) is a rational curve fibration. In both cases \(\mu_{m_o}\) has a fixed point on \(X_N\). We prove the existence of fixed point on \(X_i\) by a descending induction on \(i\). So we assume that \(X_{i+1}\) has a fixed point, say \(P\). If \(\psi_i: X_i \rightarrow X_{i+1}\) is a flip, we may assume that \(P\) is contained in the flipped curve \(C_{i+1} \subset X_{i+1}\). In this case \(\mu_{m_o}\) acts on a connected closed subset of the flipping curve \(C_i \subset X_i\). Since \(C_i\) is a tree of rational curves, \(\mu_{m_o}\) has a fixed point on \(C_i\). Similar argument works in the case where \(\psi_i: X_i \rightarrow X_{i+1}\) is a contraction of a \(\mu_{m_o}\)-invariant divisor to a curve. Thus we may assume that \(\psi_i: X_i \rightarrow X_{i+1}\) is a divisorial contraction that contracts a \(\mu_{m_o}\)-invariant divisor \(E \subset X_i\) to \(P\). Let \(\gamma\) be the log canonical threshold of \((X_i, E)\) and let \(W_i \subset X_i\) be a minimal center of log canonical singularities of \((X_i, \gamma E)\). As in the del Pezzo bundle case above, considering the action of \(\mu_{m_o}\) on \(W_i\) we find a fixed point. This proves our proposition. \(\square\)

**Lemma 2.12.** Let \(S\) be a rational surface. Then any action of a finite cyclic group on \(S\) has a fixed point.

**Proof.** Let \(\mu_n\) be the cyclic group acting on \(S\). Replacing \(S\) with its normalization and the minimal resolution, we may assume that \(S\) is smooth.
Since $S$ is rational, $H^i(S, \mathbb{C}) = 0$ if $i$ is odd. Then the assertion follows by the Lefschetz fixed point formula. □

3. Preparations

**Notation 3.1.** Let $f : X \to Z$ be a weak del Pezzo fibration. Compactify $X$ and $Z$ and resolve $X$ only above the added points of $Z$. Thus we may assume that both $X$ and $Z$ are projective. Let $F_g$ be a general fiber and let $f^*(o) = m_oF_o$ be a special fiber of multiplicity $m_o$. Write $m_o = m\alpha$, where $m$ and $\alpha$ are positive integers and put $D := \alpha F_o$. Then $m_oF_o = mD = f^*(o)$.

3.2. By a variant of J. Kollár’s Higher Direct Images Theorem (see [KMM87 1-2-7], [Nak86]), one has that $R^if_*\mathcal{O}_X(K_X - jD)$ is torsion free for all $i$. But its restriction to the general fiber $F_g$ is zero for $i \neq 2$ because $-K_F$ is nef and big. Hence $R^if_*\mathcal{O}_X(K_X - jD) = 0$ for $i \neq 2$. Further, the Leray spectral sequence yields

$$H^q(X, K_X - jD) = H^{q-2}(Z, R^2f_*\mathcal{O}_X(K_X - jD)) = 0$$

for $q - 2 \neq 1$ and $j \gg 0$ because $R^2f_*\mathcal{O}_X(K_X - jD)$ is very negative. By Serre duality

$$H^{3-q}(X, jD) \simeq H^q(X, K_X - jD)^\vee = 0$$

for $q \neq 3$ and $j \gg 0$.

Finally, $H^i(X, jD) = 0$ for all $i > 0$, $j > j_0 \gg 0$. We also have

$$H^0(X, jf^*(o) + lD) \simeq H^0(X, jf^*(o))$$

for $l = 0, \ldots, m - 1$. Put $j_1 := \lfloor j_0/m \rfloor$ and

$$\Theta_l := \frac{1}{mj_1}h^0(X, j_1f^*(o)) - \frac{1}{mj_1 + l}h^0(X, j_1f^*(o) + lD).$$

Thus for $l = 0, \ldots, m - 1$ we have

$$\Theta_l = \frac{l}{mj_1(mj_1 + l)}h^0(X, j_1f^*(o)) = \frac{l(j_1 - p_a + 1)}{mj_1(mj_1 + l)},$$

where $p_a$ is the genus of $Z$. On the other hand, by (2.7)

$$\Theta_l = -\frac{1}{mj_1 + l} \sum_{P \in B} c_P(lD) + \frac{l}{mj_1(mj_1 + l)}\chi(\mathcal{O}_X).$$

Comparing (3.3) and (3.4) we get

$$m \sum_{P \in B} c_P(lD) = -l, \quad l = 0, \ldots, m - 1.$$

3.6. Denote

$$\Delta_a := \chi(\mathcal{O}_X(-K - aF_o)) - \chi(\mathcal{O}_X(-K - (a + 1)F_o)),$$

$$\delta_a := \sum_{P \in B} c_P(-K - aF_o) - \sum_{P \in B} c_P(-K - (a + 1)F_o).$$
As above, for \( a = 0, \ldots, m_o - 2 \), the following equality holds

\[
\Delta_a = \frac{13}{12} K^2 \cdot F_o + \frac{1}{12} F_o \cdot c_2(X) + \sum_{P \in B} c_P(-K - aF_o) - \sum_{P \in B} c_P(-K - (a + 1)F_o) = \frac{13}{12} K^2 \cdot F_g + \frac{1}{12} m_o F_g \cdot c_2(X) + \delta_a.
\]

Since \( K^2 \cdot F_g = K^2 \cdot F_g \) and \( F_g \cdot c_2(X) = c_2(F_g) = 12 - K^2 \cdot F_g \), we have

\[
(3.7) \quad \Delta_a = \frac{K^2 \cdot F_g + 1}{m_o} + \delta_a.
\]

### 3.8. Some computations.

Let \((X, P)\) be a cyclic quotient singularity of type \( \frac{1}{r}(a, -a, 1) \), let \( D \) be a Weil divisor on \( X \), and let \( m \) be a natural number. We have \( D \sim qK_X \) for some \( 0 \leq q < r \). Denote

\[
\Xi_{P,m} := \sum_{l=1}^{m-1} c_P(lD).
\]

We also will write \( \Xi_P \) or \( \Xi \) instead of \( \Xi_{P,m} \) if no confusion is likely. By definition

\[
(3.10) \quad \Xi_{P,m} = \sum_{l=1}^{m-1} \left( -q \ell \frac{r^2 - 1}{12r} + \sum_{j=1}^{q-1} \frac{b_j(r - b_j)}{2r} \right).
\]

We compute \( \Xi \) in some special situation:

**Lemma 3.11.** Let \( s := \gcd(r, q) \). Write \( r = sm \) and \( q = sk \) for some \( s, k \in \mathbb{Z}_{>0} \) (so that \( \gcd(m, k) = 1 \)). Then

\[
(3.12) \quad \Xi_{P,m} = \frac{-m^2 - 1}{24m} r.
\]

**Proof.** By our assumption \( \gcd(m, k) = 1 \) the parameter \( \overline{q\ell} = \overline{sk\ell} \) runs through all the values \( sl, l = 1, \ldots, m - 1 \). Hence,

\[
\Xi = -\sum_{l=1}^{m-1} s l \frac{r^2 - 1}{12r} + \sum_{l=1}^{m-1} \sum_{j=1}^{q-1} \frac{b_j(r - b_j)}{2r}.
\]

Since \( \overline{b_j}(r - \overline{b_j}) = \overline{b_{j'}}(r - \overline{b_{j'}}) \) for \( j + j' = r \), we have

\[
\sum_{j=1}^{s l} \frac{b_j(r - b_j)}{2r} = \sum_{j=r-s l+1}^{r-1} \frac{b_j(r - b_j)}{2r}.
\]
Therefore,

\[
\Xi = -\frac{m(m-1)s r^2 - 1}{2} + \frac{m-1}{2} \sum_{j=1}^{r-1} \frac{bj(r - bj)}{2r} - \frac{1}{2} \sum_{l=1}^{m-1} \frac{bsl(r - bsl)}{2r} = \\
- \frac{(m-1)r r^2 - 1}{2} + \frac{m-1}{2} \sum_{j=1}^{r-1} \frac{bj(r - bj)}{2r} - \frac{1}{2} \sum_{l=1}^{m-1} \frac{sl(r - sl)}{2r} = \frac{m-1}{2} c_P(rK) \\
- \frac{s}{4} \sum_{l=1}^{m-1} l + \frac{s^2}{4r} \sum_{l=1}^{m-1} l^2 = \frac{-sm(m-1)}{8} + \frac{s^2}{24r}(m-1)m(2m-1) = \\
= -\frac{m-1}{8} \left(r - \frac{s}{3}(2m-1)\right) = -\frac{m-1}{24} \left(r + \frac{r}{m}\right).
\]

(We used \(sm = r\) and \(c_P(rK) = 0\).) This proves our lemma. \(\square\)

**Lemma 3.13.** If \(m = m_1m_2\), where \(m_1D\) is Cartier, then

\[
\Xi_{p,m} = m_2 \Xi_{p,m_1}.
\]

**Proof.** Follows by (3.9) because \(c_P(tD)\) is \(r\)-periodic. \(\square\)

4. **Proof of Theorem 1.1**

Notation as in 3.1. Near each singular point \(P \in X\) of index \(r_P\) we write

\[D \sim q_P K_X.\]

Then \(mq_P K_X \sim mD\) is Cartier near \(P\). Hence,

(4.1) \[mq_P \equiv 0 \mod r_P.\]

From (3.9) we have

(4.2) \[\sum_{P \in B} \Xi_{p,m} = -\sum_{l=1}^{m-1} \frac{l}{m} = -\frac{m-1}{2}.\]

**Proposition 4.3.** Notation as above. If \(m\) is prime, then we have one of the following possibilities:

(4.3.1) \(m = 2, B(D) = (8),\)
(4.3.2) \(m = 2, B(D) = (2, 6),\)
(4.3.3) \(m = 2, B(D) = (4, 4),\)
(4.3.4) \(m = 2, B(D) = (2, 2, 4),\)
(4.3.5) \(m = 2, B(D) = (2, 2, 2, 2),\)
(4.3.6) \(m = 3, B(D) = (9),\)
(4.3.7) \(m = 3, B(D) = (3, 3, 3),\)
(4.3.8) \(m = 3, B(D) = (3, 6),\)
(4.3.9) \(m = 5, B(D) = (5, 5),\)
(4.3.10) \(m = 5, B(D) = (10),\)
(4.3.11) \(m = 11, B(D) = (11).\)
Proof. By (4.1) we have \( mq_P \equiv 0 \mod r_p \) and \( r_P \equiv 0 \mod m \) for all \( P \in B(D) \) (otherwise \( q_P \equiv 0 \mod r_P \) and \( P \notin B(D) \)). Put \( s_p := r_P/m \). Then \( q_P = s_p k_p \) for some \( k_P \in \mathbb{Z}_{>0} \). Since \( \gcd(k_P, q_P) = 1 \), the assumption of Lemma 3.14 holds for each point \( P \in B(D) \). Combining (3.12) with (4.2) we obtain

\[
(m + 1) \sum_{P \in B} r_P = 12m.
\]

Hence, \( m \in \{2, 3, 5, 11\} \). Using the fact \( r_P \equiv 0 \mod m \) we get the statement. \( \square \)

**Proposition 4.4.** Cases (4.3.10) and (4.3.11) do not occur. In particular, the assertion of Theorem 4.1 holds if \( m_o \) is prime.

**Proof.** Consider the case (4.3.11). Since \( \gcd(q, m) = 1 \), there is \( 0 < l < r = m \) such that \( ql \equiv 1 \mod m \). Then by (3.3) and (2.8) we have

\[
-\frac{l}{11} = c_p(lD) = c_p(K) = -\frac{r^2 - 1}{12r} = -\frac{10}{11},
\]

so \( l = q = 10 \). Then again by (3.3) and (2.8)

\[
-\frac{1}{11} = c_p(D) = c_p(-K) = \frac{r^2 - 1}{12r} - \frac{b(r - b)}{2r} = -\frac{10}{11} - \frac{b(11 - b)}{22}.
\]

Hence, \( b(11 - b) = 22 \) and \( b \) cannot be coprime to 11, a contradiction.

Consider the case (4.3.10). Since \( mq = 5q \equiv 0 \mod r = 10 \), \( q \) is even. There is \( 0 < l < 5 \) such that \( ql \equiv 2 \mod r \). Then by (3.3) we have

\[
-\frac{l}{5} = c_p(lD) = c_p(2K) = -\frac{2(r^2 - 1)}{12r} + \frac{b(r - b)}{2r} = -\frac{b(10 - b) - 33}{20}.
\]

Thus \( b(10 - b) + 4l = 33 \), \( b \in \{3, 7\} \), \( l = 3 \), and \( q = 4 \). Again by (3.3)

\[
-\frac{1}{5} = c_p(D) = -\frac{4(r^2 - 1)}{12r} + \sum_{j=1}^{3} \frac{b_j(r - b_j)}{2r} = -\frac{33}{10} + \sum_{j=1}^{3} \frac{3j(10 - 3j)}{20} = -\frac{3}{5},
\]

a contradiction. This proves our lemma. \( \square \)

**Corollary 4.5.** For every prime divisor \( d \) of \( m_o \) we have \( d \in \{2, 3, 5\} \).

**Proof.** Apply Propositions 4.3 and 4.4 with \( D = \frac{m_o}{d} F_o. \) \( \square \)

Let \( P_i \) be points of \( B(F_o) \). Let \( P = P_i \) be a point in \( B(F_o) \) whose index \( r_{P_i} \) is divisible by \( m_o \) (see Proposition 2.11). For short, below we will write \( r_i, b_i, q_i, \) etc instead of \( r_{P_i}, b_{P_i}, q_{P_i} \), respectively.

**Corollary 4.6.** \( m_o \) is not divisible by \( m \in \{16, 27, 25, 10, 15, 12, 18\} \).

**Proof.** Let \( d = 2, 3 \) or 5 be a prime divisor of \( m_o \) and let \( D = \frac{m_o}{d} F_o \). Then \( dD = f_o(o) \) and \( D \) is not Cartier at \( P_i \). In this case, by Propositions 4.3 and 4.4 the index of \( (X, P_i) \) is at most 9, a contradiction. \( \square \)
Corollary 4.7. If \( m_o \) is not prime, then \( m_o \in \{4, 6, 8, 9\} \).

Lemma 4.8. If \( m_o = 6 \), then \( \mathcal{B}(F_o) = (2, 3, 6) \). Moreover, \( \gcd(r_P, q_P) = 1 \) for all \( P \in \mathcal{B}(F_o) \).

Proof. Take \( D = 3F_o \). Then \( 2D \sim f^*(o) \) but \( D \) is not Cartier at \( P_1 \). Hence \((X, P_1)\) is of index 6 and for \( D \) we are in the case \([4.3.2]\) that is, \( \mathcal{B}(3F_o) = (2, 6) \). At all points \( P_i \notin \mathcal{B}(3F_o) \) the divisor \( 3F_o \) is Cartier. Similarly, take \( D' = 2F_o \). Then for \( D \) we get the case \([4.3.8]\) that is, \( \mathcal{B}(2F_o) = (3, 6) \). Hence \( \mathcal{B}(F_o) \) contains three points \( P_1, P_2, P_3 \) of indices 6, 2, 3, respectively, and in all other points both \( D' = 2F_o \) and \( D = 3F_o \) are Cartier. Hence \( F_o = D - D' \) is Cartier outside of \( P_1, P_2, P_3 \) and \( \mathcal{B}(F_o) = (2, 3, 6) \). \( \square \)

Lemma 4.9. If \( m_o = 4 \), then \( \mathcal{B}(F_o) = (2, 4, 4) \). Moreover, \( \gcd(r_P, q_P) = 1 \) for all \( P \in \mathcal{B}(F_o) \).

Proof. Clearly, \( 2F_o \) is Cartier at all points of index 2. Hence \( \mathcal{B}(2F_o) \) contains no such points and for \( \mathcal{B}(2F_o) \) we are in the case \([4.3.1]\) or \([4.3.3]\). For all points \( P_i \notin \mathcal{B}(2F_o) \) the divisor \( 2F_o \) is Cartier at \( P_i \). Hence, \( q_i = r_i/2 \).

Assume that \( \mathcal{B}(2F_o) = (8) \). Let \( P \in \mathcal{B}(2F_o) \). Since \( 4F_o \) is Cartier, \( 4q_P \equiv 0 \) mod 8 (but \( 2q_P \neq 0 \) mod 8). By Lemma 3.11 and 3.13 we have

\[
\Xi_{P, 4} = -\frac{5}{4}, \quad \Xi_{P, 8} = 4\Xi_{P, 2} = -\frac{r_j}{4}, \quad j \neq 1.
\]

Therefore, by (4.2) the following holds \( \sum_{i \neq 1} r_i = 1 \), a contradiction.

Hence \( \mathcal{B}(2F_o) = (4, 4) \). At both points \( P_i \in \mathcal{B}(2F_o) \) we have \( F_o \sim \pm K_X \) near \( P_i \). Again by Lemma 3.11 and 3.13

\[
\Xi_{P, 4} = -\frac{5}{8}, \quad i = 1, 2, \quad \Xi_{P, 4} = 2\Xi_{P, 2} = -\frac{r_j}{8}, \quad j \neq 1, 2.
\]

Therefore, by (4.2) we have \( \sum_{i \neq 1, 2} r_i = 2 \) and there is only one solution \( \mathcal{B}(F_o) = (4, 4, 2) \). \( \square \)

Corollary 4.10. \( m_o \neq 8 \)

Proof. Indeed, if \( m_o = 8 \), then for \( \mathcal{B}(2F_o) \) there is only one possibility from Lemma 4.9. This contradicts Proposition 2.11 \( \square \)

Lemma 4.11. \( m_o \neq 9 \).

Proof. Assume that \( m_o = 9 \). Take \( D := 3F_o \). Then \( 3D \sim f^*(o) \) but \( D \) is not Cartier at \( P_1 \). Hence, \( \gcd(q_1, r_1) = 1 \), \((X, P_1)\) is of index 9 and for \( D \) we are in the case \([4.3.6]\) that is, \( \mathcal{B}(D) = (9) \subset \mathcal{B}(F_o) \). In all points \( P_i \in \mathcal{B}(F_o), P_i \neq P_1 \) the divisor \( D = 3F_o \) is Cartier. Hence by Lemma 3.11 and 3.13 we have

\[
\Xi_{P, 9} = -\frac{10}{3}, \quad \Xi_{P, 9} = 3\Xi_{P, 3} = -\frac{r_i}{3}, \quad i \neq 1.
\]
Therefore, by (4.2)
\[-4 = \sum \Xi_{P,m} = -\frac{10}{3} - \frac{1}{3} \sum_{i \neq 1} r_i, \quad r_i = 2.\]
This contradicts \(r_i \equiv 0 \mod 3.\]

4.12. The last lemma finishes the proof of Theorem 1.1. It remains to compute values \(b_k, q_k,\) and \(K_{F_0}^2\) in Table 1.

First we compute the possible values of \(q_i.\) We may assume that \(1 \leq q_i < r_i.\) In regular cases \(I_{2,3,6}, I_{5,5}, I_{3,3,3}, I_{2,4,4}, I_{2,2,2,2}\) we have \(\gcd(q_i, r_i) = 1\) (see Lemmas 4.8 and 4.9) and \(m_o \geq r_i\) for all \(i.\) Take \(1 \leq l \leq m_o - 1\) so that \(q_i l \equiv 1 \mod r_i.\) Then by (2.8) and (3.5) the following equality holds
\[\sum_i c_P(lF_o) = \sum_i c_P(K) = -\sum_i \frac{r_i^2 - 1}{12r_i} = -\frac{l}{m_o}.\]
From this we immediately obtain \(l \equiv q_i \equiv -1 \mod r_i\) for all \(i.\)

If \(m_o = 2\) (cases \(I_{1\times 2}, I_{2,2,4}, I_{4,4}, I_{2,6}, I_{8}\)), then \(2F_0\) is Cartier. Hence \(q_i = r_i/2.\) It remains to consider only cases \(I_9\) and \(I_{3,6}.\) In case \(I_9,\) since \(3F_0\) is Cartier, we have \(q := q_1 = 3\) or 6. If \(q = 3,\) then by (3.5) we have
\[-1 = 3c_P(F_o) = 3c_P(3K) = -\frac{40}{6} + \frac{b(9 - b)}{6} + \frac{2b(9 - 2b)}{6}.\]
Hence, \(34 = b(9 - b) + 2b(9 - 2b)\) and \(5b^2 \equiv 2 \mod 9.\) This immediately implies \(b \equiv \pm 2.\) Similarly, if \(q = 6,\) then \(b^2 \equiv -2 \mod 9\) and \(b \equiv \pm 4.\)

Finally consider the case \(I_{3,6}.\) Then by (2.8) and (2.6)
\[c_P(F_o) = \begin{cases} -2/9 & \text{if } q_1 = 1 \\ -1/9 & \text{if } q_1 = 2 \end{cases} \quad c_P(F_o) = \begin{cases} -5/9 & \text{if } q_1 = 2 \\ -1/9 & \text{if } q_1 = 4 \end{cases}\]
The equality \(c_{P_1}(F_o) + c_{P_2}(F_o) = -1/3\) (see (3.5)) holds only if \(q_1 = 1, q_2 = 4.\)

Corollary 4.13. The fiber \(F_o\) is regular if and only if \(q_i \equiv -1 \mod r_i\) for all \(i.\) In particular, for regular \(F_o\) near each point \(P \in F_o\) where \(F_o\) is not Cartier we have \(K_X + F_o \sim 0.\)

4.14. Now we find the possible values of \(b_i.\) In all cases except for \(I_{5,5}\) and \(I_9\) the relations \(\gcd(r_i, q_i) = 1\) is sufficient to get the conclusion. The case \(I_9\) was treated above. Consider the case \(I_{5,5}.\) Then by (2.8) and (3.5) we have
\[10 = b_1(5 - b_1) + b_2(5 - b_2). \quad \text{Hence } b_1^2 + b_2^2 \equiv 0 \mod 5.\]

4.15. To obtain the possible values for \(K_{F_0}^2\) we use (3.7) with \(a = 0.\) Since \(\Delta_a\) is an integer, it is sufficient to compute \(\delta_0 = c_P(-K) - c_P(-K - F_o).\)
Table 2 gives all values of \(\delta_0.\) For example, if \(F_o\) is regular, then \(q_P \equiv -1\)
mod $r_P$ for all $P$ and $\delta_0 = \sum c_P(-K) = \sum c_P(F_o)$. So by (2.8) and (3.5) we have $\delta_0 = -1/m_o$. Assume that $q_P = r_P/2$ (and all the $r_p$ are even). Then

$$\delta_0 = \sum_{P \in B} \left( c_P(-K) - c_P \left( \frac{r_P - 2}{2} K \right) \right).$$

Hence by (2.8) and (2.6)

- $r_P = 2 \implies \delta_0 = c_P(-K) = -1/8$,
- $r_P = 4 \implies \delta_0 = c_P(-K) - c_P(K) = 1/4$,
- $r_P = 6 \implies \delta_0 = c_P(-K) - c_P(2K) = 5/8$,
- $r_P = 8 \implies \delta_0 = c_P(-K) - c_P(3K) = 1$ or $0$ if $b_P = 1$ or $3$, respectively.

This immediately gives the values of $\delta_0$ in cases $I_{2,2,4}$, $I_{4,4}$, $I_{2,6}$, and $I_8$. Cases $I_{3,6}$ and $I_9$ are similar.

### Table 2.

| $\delta_0$ | regular | $I_{3,6}$ | $I_9$ | $I_{2,2,4}$ | $I_{4,4}$ | $I_{2,6}$ | $I_8$ |
|------------|---------|-----------|------|-------------|-----------|----------|------|
| $-\frac{1}{m_o}$ | $\frac{2}{3}$ | $\frac{5-m}{9}$ | $0$ | $\frac{1}{2}$ | $\frac{1}{2}$ | $\frac{3-|b_1|}{2}$ |

## 5. Examples

In this section we construct some examples of del Pezzo bundles with multiple fibers. We use notation of Construction 2.9. We start with regular case.

**Proposition 5.1.** Let $f': X' \to Z' \ni o'$ be a Gorenstein del Pezzo bundle. Assume that the central fiber $F'_o := f'^{-1}(o')$ has only Du Val singularities. Assume also that the cyclic group $\mu_{m_o}$ acts on $X'$ and $Z'$ so that

- (i) the action on $Z'$ is free outside of $o'$,
- (ii) $f'$ is $\mu_{m_o}$-equivariant,
- (iii) the action on $F'_o$ is free in codimension one,
- (iv) the quotient $F_o := F'_o/\mu_{m_o}$ has only Du Val singularities.

Then $f: X = X'/\mu_{m_o} \to Z = Z'/\mu_{m_o}$ is a del Pezzo bundle with regular central fiber of multiplicity $m_o$ and, moreover, $F_o \sim -K_X$ near each point $P \in X$.

**Proof.** In notation of Construction 2.9 it is sufficient to show that $X$ has only terminal singularities. Since $X'$ has only terminal singularities and the action of $\mu_{m_o}$ is free outside of a finite number of points $P'_k$ lying on $F'_o$, the quotient $X$ is smooth outside of $\pi(P'_k) \in F_o$. By the inversion of adjunction [Kol92, 17.6] the pair $(X, F_o)$ is PLT near $F_o$. Since $F_o$ is Gorenstein, the
divisor $K_X + F_o$ is Cartier. Hence the pair $(X, F_o)$ is canonical near $F_o$ and so $X$ has only terminal singularities.

Now we apply Proposition 5.1 to construct concrete examples.

**Example 5.2.** Let $F'_o$ be a del Pezzo surface of degree $d := K^2_{F'_o}$ with at worst Du Val singularities. Assume that the group $\mu_{m_o}, m_o \geq 2$ acts on $F'_o$ freely in codimension one and so that the quotient $F_o := F'_o/\mu_{m_o}$ has again only Du Val singularities. Clearly, $F_o$ is del Pezzo surface and $m_o K^2_{F_o} = d$. Hence, $d \geq m_o \geq 2$. For $d = 2, 3, 4,$ and $8$, according to [HW81] there is an embedding

$$F'_o \subset \mathbb{P} := \mathbb{P}(1, 1, 1, 2) \quad \text{if } d = 2$$
$$F'_o \subset \mathbb{P} := \mathbb{P}^3 \quad \text{if } d = 3$$
$$F'_o \subset \mathbb{P} := \mathbb{P}^4 \quad \text{if } d = 4$$
$$F'_o \subset \mathbb{P} := \mathbb{P}^3 \quad \text{if } d = 8$$

Moreover, if $d = 2, 3, 8$, then $F_o$ is a (weighted) hypersurface of degree $4, 3, 2$, respectively and if $d = 4$, then $F'_o$ is an intersection of two quadrics. The action of $\mu_{m_o}$ on $F'_o$ induces the action on $\mathbb{P}$. We fix a linearization of this action and take semi-invariant coordinates $x_i$ in $\mathbb{P}$. Now we define $\mu_{m_o}$-equivariant del Pezzo bundle $f': X' \to Z'$. If $F'_o$ is smooth, we can take $X' = F'_o \times \mathbb{C}_t$. In general case, $X'$ is embedded into $\mathbb{P} \times \mathbb{C}_t, Z' = \mathbb{C}_t$ and $f'$ is the projection, where $t$ is a coordinate in $\mathbb{C}$ with $wt = 1$. Consider for example the case $d \leq 3$ (case $d = 4$ is similar). Let $\phi = \phi(x_1, x_2, x_3, x_4)$ be the defining equation of $F'_o$ and let $\gamma_k$ be all monomials of weighted degree $d$. For each $\gamma_k$, let $n_k$ be the smallest positive integer such that $n_k \equiv -wt \gamma_k$ mod $m_o$. Then the polynomial $\psi(x_1, \ldots, x_4; t) := \phi + \sum c_k x^n_k \gamma_k, c_k \in \mathbb{C}$ is $\mu_{m_o}$-semi-invariant. Let $X' = \{\psi = 0\} \subset \mathbb{P} \times \mathbb{C}_t$. By Bertini’s theorem, for sufficiently general constants $c_k$, fibers $F'_i$ of $f'$ over $t \neq 0$ are smooth del Pezzo surfaces. Hence we can apply Proposition 5.1 and get a del Pezzo bundle with a regular fiber of multiplicity $m_o$.

Note that the map $F'_o \to F_o$ is étale outside of Sing $F_o$. Hence there is a surjection $\pi_1(F_o \setminus \text{Sing } F_o) \to \mu_{m_o}$. Conversely, assume that $F_o$ is a del Pezzo surface with Du Val singularities such that $\pi_1(F_o \setminus \text{Sing } F_o) \to \mu_{m_o}$. Then there is an étale outside of Sing $F_o$ cyclic $\mu_{m_o}$-cover $\nu: F'_o \to F_o$. Since $K_{F'_o} = \nu^*K_{F_o}, F'_o$ is also a del Pezzo surface with Du Val singularities. The fundamental groups of smooth loci of Du Val del Pezzo surfaces are described in [MZ88], [MZ93]. For example, from [MZ88] we have the following examples with $\rho(F_o) = 1$ (we do not list all the possibilities):

| $K^2_{F'_o}$ | Sing $F_o$ | $m_o$ | $K^2_{F'_o} = K^2_{F_o}$ | $\rho(F'_o)$ | $F'_o$, Sing $F'_o$ | type |
|--------------|------------|-------|-----------------------|-------------|-----------------|------|
| 1 | $A_1A_2A_5$ | 6 | 6 | 4 | smooth | $I_{2,3,6}$ |
Example 5.3. In some cases we can give more explicit construction. As was mentioned above, if $F'_o$ is smooth, we can take $X' = Z' \times F'_o$. Consider the following cases:

- $F'_o = \mathbb{P}^2$, $\mu_3$ acts on $\mathbb{P}^2_{x,y}$ by $x \mapsto \epsilon x$, $y \mapsto \epsilon^{-1} y$ (here $x$, $y$ are non-homogeneous coordinates on $\mathbb{P}^2$ and $\epsilon^3 = 1$). Then $\mathbb{P}^2/\mu_3$ is a toric del Pezzo surface of degree 3 having three singular points of type $A_2$. The quotient $f: X \to Z$ is a del Pezzo bundle with special fiber of type $I_{3,3,3}$.
- $F'_o = \mathbb{P}^1 \times \mathbb{P}^1$, $\mu_2$ acts on $\mathbb{P}^1_x \times \mathbb{P}^1_y$ by $x \mapsto -x$, $y \mapsto -y$. Then $\mathbb{P}^1 \times \mathbb{P}^1/\mu_2$ is a del Pezzo surface of degree 4 having four singular points of type $A_1$. The quotient $f: X \to Z$ is a del Pezzo bundle with special fiber of type $I_{2,2,2,2}$.
- $F'_o = \mathbb{P}^1 \times \mathbb{P}^1$, $\mu_4$ acts by $x \mapsto y$, $y \mapsto -x$. Then $\mathbb{P}^1 \times \mathbb{P}^1/\mu_4$ is a del Pezzo surface of degree 2 having two points of type $A_3$ and one point of type $A_1$. The quotient $f: X \to Z$ is a del Pezzo bundle with special fiber of type $I_{2,4,4}$.

Now we give some examples of irregular multiple fibers.

Example 5.4. Recall that any smooth del Pezzo surface of degree 1 can be realized as a weighted hypersurface of degree 6 in $\mathbb{P} = \mathbb{P}(1,1,2,3)$. Let

$$\phi(x_1, x_2, y, z) = a_1x_1^6 + a_2x_2^6 + y^2(b_1x_1^2 + b_2x_2^2) + cz^2, \quad a_i, b_j, c \in \mathbb{C}^*$$

be a polynomial of weighted degree 6, where $x_1, x_2, y, z$ are coordinates in $\mathbb{P}$ with wt $x_i = 1$, wt $y = 2$, wt $z = 3$. Consider the hypersurface $F'_o \subset \mathbb{P}$ given by $\phi = 0$. By Bertini’s theorem, for sufficiently general $a_i, b_j, c$, the surface $F'_o$ is smooth outside of $P' := (0 : 0 : 1 : 0)$. Consider the subvariety $X'$ in $\mathbb{P} \times \mathbb{C}_t$ given by $\phi + ty^3 = 0$ and let $f': X' \to Z' = \mathbb{C}$ be the natural
projection. Since $F'_o$ is the scheme fiber of the projection $f' : X' \to Z'$, the variety $X'$ is smooth outside of $P'$. We identify $F'_o$ with the fiber over $t = 0$. Then $f'$ is a del Pezzo bundle of degree 1 having a unique singular point of type $\frac{1}{2}(1,1,1)$ at $P'$.

Now let $\mu_2$ acts on $\mathbb{P} \times \mathbb{C}$ and $X'$ by

$$(x_1, x_2, y, z; t) \mapsto (x_1, -x_2, -y, -z; -t).$$

The locus of fixed points $\Lambda$ consists of the line $L := \{x_1 = y = t = 0\}$ and two isolated points $P' := (0 : 0 : 1 : 0 : 0)$ and $P_1 := (1 : 0 : 0 : 0 : 0)$. Then $F'_o \cap \Lambda = \{P', Q_1, Q_2\}$, where $Q_1 \neq Q_2$ are points given by $x_1 = y = a_2 x_2^6 + z^2 = t = 0$. Let $f : X = X'/\mu_2 \to Z = Z'/\mu_2$ be the quotient of $f'$.

Since the action of $\mu_2$ on $X'$ is free in codimension one, $-K_X$ is $f$-ample and $F_o := F'_o/\mu_2$ is a fiber of multiplicity 2. We show that $X$ has only terminal singularities. By the above, $X$ is smooth outside of images of $P', Q_1, Q_2$.

Since the $(X', Q_i)$ are smooth points, quotients $(X', Q_i)/\mu_2$ are terminal of type $\frac{1}{2}(1,1,1)$. Consider the affine chart $\{y \neq 0\} \simeq \mathbb{C}^4_{x'_1,x'_2,z',t}/\mu_2(1,1,1,0)$ containing $P'$. Here $X'$ is given by the equation $\phi(x'_1, x'_2, z', t) + t = 0$ and the action of $\mu_2$ on $\mathbb{P}$ induces the following action of $\mu_4$:

$$(x'_1, x'_2, z', t) \mapsto (i x'_1, -i x'_2, i z', -t), \quad i = \sqrt{-1}.$$ 

Thus the quotients $(X', P')/\mu_2$ is a terminal cyclic quotient of type $\frac{1}{4}(1,-1,1)$. Therefore, $f : X \to Z$ is a del Pezzo bundle with special fiber of type $I_{2,2,4}$.

**Example 5.5.** As above let $\mathbb{P} = \mathbb{P}(1,1,2,3)$ and let

$$\phi(x_1, x_2, y, z) = a_1 x_1^6 + a_2 x_2^6 + cy^3, \quad a_i, c \in \mathbb{C}^*$$

be a $\mu_2$-invariant polynomial of weighted degree 6. Consider the hypersurface $F'_o \subset \mathbb{P}$ given by $\phi = 0$. Again for sufficiently general $a_i, c$, the surface $F'_o$ is smooth outside of $P'' := (0 : 0 : 0 : 1)$. Consider the subvariety $X'$ in $\mathbb{P} \times \mathbb{C}_t$ given by $\phi + t z^2 = 0$ and let $f' : X' \to Z' = \mathbb{C}$ be the natural projection. Then $f'$ is a del Pezzo bundle of degree 1 having a unique singular point of type $\frac{1}{3}(1,1,-1)$ at $P''$. Now let $\mu_3$ acts on $\mathbb{P} \times \mathbb{C}$ and $X'$ by

$$(x_1, x_2, y, z; t) \mapsto (x_1, \epsilon x_2, \epsilon y, \epsilon z, \epsilon t), \quad \epsilon := \exp(2\pi i / 3).$$

The only fixed point on $X'$ is $P''$. As above, one can check that $(X', P'')/\mu_3$ is a terminal point of type $\frac{1}{6}(-1,2,1)$. Therefore, $X/\mu_3 \to Z'/\mu_3$ is a del Pezzo bundle with special fiber of type $I_6$.

**Example 5.6.** Let $\mathbb{P} := \mathbb{P}(1,1,2,2)$, let $x_1, x_2, x_3, y_1, y_2$ be coordinates, and let $X' \subset \mathbb{P} \times \mathbb{C}$ be subvariety given by

$$\begin{cases}
    c_1 y_1^2 + c_2 y_2^2 = a_1 x_1^4 + a_2 x_3^4 + a_3 x_3^4 \\
    ty_2 = b_1 x_1^2 + b_2 x_2^2 + b_3 x_3^2,
\end{cases}$$

where
where \( t \) is a coordinate on \( \mathbb{C} \) and \( a_i, b_j, c_k \) are sufficiently general constants. By Bertini’s theorem \( X' \) is smooth outside of \( \{x_1 = x_2 = x_3 = 0\} \subset \text{Sing} \mathbb{P} \). It is easy to check that \( X' \cap \text{Sing} \mathbb{P} \) consists of two points

\[
\{P'_1, P'_2\} = \{t = x_1 = x_2 = x_3 = 0, \ c_1y_1^2 + c_2y_2^2 = 0\}
\]

and these points are terminal of type \( \frac{1}{2}(1, 1, 1) \). The projection \( X' \to \mathbb{C} \) is a del Pezzo bundle of degree 2. Define the action of \( \text{H} \) by

\[
(x_1, x_2, x_3, y_1, y_2; t) \mapsto (x_1, x_2, -x_3, y_1, -y_2; -t).
\]

There are four fixed points

\[
\{Q'_1, \ldots, Q'_4\} = \{t = x_3 = y_2 = 0, \ c_1y_1^2 = a_1x_1^4 + a_2x_2^4, b_1x_1^2 + b_2x_2^2 = 0\}.
\]

The quotient \( f: X'/\text{H} \to \mathbb{C}/\text{H} \) is a del Pezzo bundle of type \( I_{2,2,2,2} \). Note however that the image \( P \) of \( \{P'_1, P'_2\} \) on \( X'/\text{H} \) is a point of type \( \frac{1}{2}(1, 1, 1) \) and \( F_0 \) is Cartier at \( P \) (i.e., \( P \notin \mathcal{B}(F_0) \)).

**Example 5.7.** In the above notation define another action of \( \text{H} \):

\[
(x_1, x_2, x_3, y_1, y_2; t) \mapsto (x_1, x_2, -x_3, -y_1, -y_2; -t).
\]

Then the quotient \( f: X'/\text{H} \to \mathbb{C}/\text{H} \) is a del Pezzo bundle of type \( I_{4,4} \).

**Example 5.8.** Let \( \mathbb{P} := \mathbb{P}(1, 1, 1, 2) \), let \( x_1, x_2, x_3, x_4, y \) be coordinates, and let \( X' \subset \mathbb{P} \times \mathbb{C} \) be subvariety given by

\[
\begin{align*}
& a_1x_1^2 + a_2x_2^2 + a_3x_1x_2 + a_4x_3x_4 = ty \\
& b_1x_1^3 + b_2x_2^3 + b_3x_3^3 = x_4y
\end{align*}
\]

where \( t \) is a coordinate on \( \mathbb{C} \) and \( a_i, b_j \) are sufficiently general constants. Then the variety \( X' \) is smooth outside of the point \( P' = \{x_1 = x_2 = x_3 = x_4 = 0\} \) and \( P' \in X' \) is of type \( \frac{1}{6}(1, 1, 1) \). The projection \( X' \to \mathbb{C} \) is a del Pezzo bundle of degree 3. Define the action of \( \text{H} \) by

\[
(x_1, x_2, x_3, x_4, y; t) \mapsto (\omega^{-1}x_1, \omega^{-1}x_2, \omega x_3, x_4, y; \omega t).
\]

There are two fixed points \( \{t = x_1 = x_2 = x_3 = x_4y = 0\} \) and quotients of these points are of types \( \frac{1}{6}(1, 1, -1) \) and \( \frac{1}{3}(1, -1) \). Hence the quotient \( f: X'/\text{H} \to \mathbb{C}/\text{H} \) is a del Pezzo bundle of type \( I_{3,6} \).

6. **On del Pezzo bundles with fibers of multiplicity \( \geq 5 \).**

**Notation 6.1.** Let \( f: X \to Z \ni o \) be the germ of a del Pezzo bundle and let \( m_oF_o = f^*(o) \) be a fiber of multiplicity \( m_o \). In this section we assume that \( m_o \geq 5 \), i.e., \( F_o \) is of type \( I_{2,3,6} \) or \( I_{5,5} \).

**Conjecture 6.2.** In notation of [6.1] \( f \) is a quotient of a Gorenstein del Pezzo bundle by a cyclic group acting free in codimension 2 on \( X \).

**Proposition 6.3.** Notation as in [6.1] If either
(i) \( B(F_o) = B \), that is, each point \( P \in F_o \) where \( F_o \) is Cartier is Gorenstein on \( X \), or

(ii) a general member \( S \in | - K_X | \) has only Du Val singularities (Reid’s general elephant conjecture),

then \( \text{(6.2)} \) holds.

**Proof.** Assume that (i) holds. By Table \( \text{I} \) near each singular point \( K_X + F_o \sim 0 \). Apply Construction \( \text{2.9} \). Then \( F'_o = \pi^* F_o \) is Cartier. Since \( \pi \) is étale in codimension one, \( K_{X'} + F'_o \sim 0 \). Hence, \( X' \) is Gorenstein.

Now assume that (ii) holds. Then \( \varphi: S \to Z \) is an elliptic fibration with Du Val singularities. We have \( K_S = (K_X + S)|_S \sim 0 \). Let \( \mu: \tilde{S} \to S \) be the minimal resolution. Since \( S \) has only Du Val singularities, \( K_{\tilde{S}} \sim 0 \). In particular, \( \psi: \tilde{S} \to Z \) is a minimal elliptic fibration. By Kodaira’s canonical bundle formula \( \psi \) has no multiple fibers [Kod64 Th. 12]. Since \( \psi^* o \) has a component of multiplicity \( \geq 5 \), for \( \psi^* o \) we have only one possibility \( \tilde{E}_8 \) in the classification of singular fibers [Kod63 Th. 6.2]. More precisely, \( \text{Supp}(\psi^* o) \) is a tree of smooth rational curves with self-intersection number \(-2\) and the dual graph \( \Gamma \) is the following:

```
1 \( \circ \) 2 \( \circ \) 3 \( \circ \) 4 \( \circ \) 5 \( \circ \) 6 \( \circ \) 4 \( \circ \) 2 \( \circ \)
\| \( \circ \)
3
```

Further we consider the case \( m_o = 6 \) (the case \( m_o = 5 \) is similar). It is easy to see that the curve \( S \cap F_o \) is irreducible and correspond to the central vertex \( v \) of \( \Gamma \). Then \( \Gamma \setminus \{ v \} \) has three connected components corresponding to points of types \( A_1 \), \( A_2 \) and \( A_5 \) on \( S \). Therefore, \( B(F_o) = B \). \( \square \)

**Proposition 6.4.** In notation of \( \text{6.1} \) assume that \( F_o \) is irreducible. let \( f_{an}: X_{an} \to Z_{an} \) be the analytic germ near \( F_o \). Then \( X_{an} \) is \( \mathbb{Q} \)-factorial over \( Z_{an} \), \( \rho(X_{an}/Z_{an}) = 1 \), and \( \rho(F_o) = 1 \).

**Warning.** Here the \( \mathbb{Q} \)-factoriality condition of \( X_{an} \) means that every global Weil divisor of the total germ \( X_{an} \) along \( F_o \) is \( \mathbb{Q} \)-Cartier, not that every analytic local ring of \( X_{an} \) is \( \mathbb{Q} \)-factorial.

**Proof.** Let \( q: \hat{X}_{an} \to X_{an} \) be a \( \mathbb{Q} \)-factorialization over \( Z_{an} \). Run the MMP over \( Z_{an} \). So, we have the following diagram

```
\begin{tikzcd}
\hat{X}_{an} \ar{d}{\hat{f}_{an}} \ar{dl}{q} & X_{an} \ar{dl}{f_{an}} \\
\tilde{X}_{an} \ar{d}{\tilde{f}_{an}} & \tilde{X}_{an} \ar{d}{\tilde{f}_{an}} \\
Z_{an} \ar{d}{\tilde{g}_{an}} & Z_{an} \ar{d}{\tilde{g}_{an}} \end{tikzcd}
```
Here \( \bar{X}_{\text{an}} \) is \( \mathbb{Q} \)-factorial over \( \bar{Z}_{\text{an}} \) and \( \rho(\bar{X}_{\text{an}}/\bar{Z}_{\text{an}}) = 1 \). Note that \( \hat{X}_{\text{an}} \twoheadrightarrow \bar{X}_{\text{an}} \) is a composition of flips and divisorial contractions that contract divisors to curves dominating \( Z_{\text{an}} \). Let \( \bar{F}_o \) be the proper transform of \( F_o \) on \( \bar{X}_{\text{an}} \). There are two possibilities:

1) \( \bar{Z}_{\text{an}} \) is a surface. Then \( g_{\text{an}} \) is a rational curve fibration with \( \rho(\bar{Z}_{\text{an}}/Z_{\text{an}}) = 1 \). Let \( C := \bar{f}_{\text{an}}(\bar{F}_o) \). Since \( X_{\text{an}} \) has only isolated singularities, \( \bar{F}_o = \bar{f}^*_{\text{an}}(C) \). Further, \( g^*_{\text{an}}(o) = nC \) for some \( n \in \mathbb{Z}_{>0} \) and \( \bar{f}^*_{\text{an}} g_{\text{an}}(o) = n\bar{f}^*_{\text{an}} C = n\bar{F}_o \). So, \( n = m_o \). By the main result of \[ \text{MP08} \] the surface \( Z_{\text{an}} \) has only Du Val singularities. Therefore, \( m_o = n \leq 2 \), a contradiction.

2) \( \bar{Z}_{\text{an}} \) is a curve. Then \( g_{\text{an}} \) is an isomorphism and \( \bar{f}_{\text{an}} : \bar{X}_{\text{an}} \twoheadrightarrow \bar{Z}_{\text{an}} \) is a del Pezzo bundle with central fiber \( \bar{F}_o \) of multiplicity \( m_o = m_o \geq 5 \). By Table 1 the degree of the generic fiber of \( \bar{f}_{\text{an}} \) (and \( f_{\text{an}} \)) is equal to \( m_o \). This means that degrees of generic fibers of \( \bar{f}_{\text{an}} \) and \( f_{\text{an}} \) coincide. In particular, the MMP \( \hat{X}_{\text{an}} \twoheadrightarrow \bar{X}_{\text{an}} \) does not contract any divisors. Hence, \( \rho(\hat{X}_{\text{an}}/Z_{\text{an}}) = \rho(X_{\text{an}}/Z_{\text{an}}) = 1 \). This implies that \( q \) is an isomorphism and \( \rho(X_{\text{an}}/Z_{\text{an}}) = 1 \).

The last assertion follows from the exponential exact sequence and vanishing \( R^1 f_{\text{an}}^* \mathcal{O}_{X_{\text{an}}} = 0 \).

\[ \square \]

**Proposition 6.5.** Notation as in 6.1 Conjecture 6.2 holds under the additional assumption that \( F_o \) has only log terminal singularities.

**Proof.** Assume that \( F_o \) has only log terminal singularities. By Table 1 near each point \( P \in B(F_o) \) we have \( K_X + F_o \sim 0 \). By Adjunction \( F_o \) has only Du Val singularities at these points. In points \( P \notin B(F_o) \) the divisor \( F_o \) is Cartier. Hence \( F_o \) has only singularities of type T [KSB88]. By Noether’s formula [HP Prop. 3.5]

\[
K_{F_o}^2 + \rho(F_o) + \sum_{P \in F_o} \mu_P = 10.
\]

Since points in \( B(F_o) \) correspond to distinct points on \( X \), we have \( \sum_{P \in B(F_o)} \mu_P \geq 8 \). Hence, \( K_{F_o}^2 = 1 \), \( \rho(F_o) = 1 \), and \( B(F_o) = B \). Now the assertion follows by Proposition 6.3. \[ \square \]
