Abstract

The study of the macro-invertebrates community of Ediba River in Cross River State was carried out from October to December, 2014 using Pollution Tolerance Index (PTI). Macro-invertebrate fauna were sampled with sweeping net using kick sampling methods. Sixteen genera, belonging to nine orders and a total of 289 individuals were encountered. The dominant groups in the order were Oligochaeta (28.1%), Diptera (24.82%), Odonata (20.3%), showing insignificant difference between the three stations at p>0.05. Taxa richness was highest in Station 1 (2.985) and least in Station 3 (1.008) showing insignificant differences across station (p>0.05). Evenness ranges from 0.337 to 0.369 showing significant difference across stations (p<0.05). Station 1 had a PTI value of 39 indicating good water quality status, while Stations 2 and Station 3 had PTI values of 6 and 4 respectively indicating poor quality water status. The abundance of pollution tolerance species of the orders, Odonata Zygoptera, Oligochaeta, Diptera and the absence of pollution sensitive species of the orders, Ephemeroptera and Trichoptera in Stations 2 and 3 indicated the poor waters quality, coupled with the low PTI values in both stations, hence need for proper management of the river.

Keywords: Bio-assessment; Biotic indices; Macro-invertebrate; Pollution tolerance index

Introduction

Macro-invertebrates communities are widely used as indicators of river ecosystem health status because they include a wide range of species, each with relatively well-known sensitivity or tolerance to river conditions [1]. They are useful in understanding the ecological health of an aquatic ecosystem, rather than using chemical and microbiological data, which at least give short-term fluctuations [2]. Macro-invertebrates are considered important because they reflect the cumulative effects of the present and past conditions; also they have low mobility (i.e. are sessile or nearly) and life cycles of several weeks or years [3]. Benthic invertebrates range in sizes from 0.2 mm to 15 cm in length as in the case of a fully grown fresh water crayfish, while most are larvae of insects, others are aquatic snails and worms [4].

Bio-monitoring studies and the use of macro-invertebrates to rate the quality of water bodies of both lotic and lentic types have been widely reviewed elsewhere [5,6]. The use of pollution tolerance index (PTI) as a method of measuring the overall health status of aquatic bodies through the use of macro-invertebrates remains the most reliable and effective method [7-9]. Macro-invertebrates which are utilized in aquatic pollution studies include: Mayflies (Ephemeroptera), caddisflies (Trichoptera), stoneflies (Plecoptera), beetles (Coleoptera), crayfish and amphipods (Crustaceans), aquatic snails (Molluscs), biting midges (Chironomids) and leeches (Hirudinea) [10-12]. This study is undertaken to investigate the composition, abundance and distribution of macro-invertebrate community and using pollution tolerance index to assess the health status of Ediba River.

Materials and Methods

Study area

The Ediba River in Abi Local Government Area of Cross River State, Nigeria is located in latitude 05° 52’49.7” N and longitude 07° 59’56.7”E (start point) and latitude 05° 53’29.0”N and longitude 07° 58’41.3”E (end point) (Figure 1). The river is the second largest of Southern Nigeria, with a width of 1000 yards during flood. It reaches its greatest depth in September – October with an average of 30 ft at the bank. The river is subjected to various anthropogenic activities. Three sampling stations were selected using geographical positioning system (GPS) and base on effluent discharge, land use patterns, human impacts, solid wastes disposal and bank type.

Station 1 lies in latitude 05° 52’49.7”N and longitude 08° 00’ 06.9”E. The bank of the river is inundated with herbs, shrubs and trees. Activities are very minimal in this area except fishing which is predominant. Station 2 lies in latitude 05° 52’22.3”N and longitude 07° 59’ 44.7”E. Aquatic macrophytes such as (Lemna pausicostata) dominated the area. There were also shrubs and human droppings and Cattle dung associated with this area. Station 3 lies in latitude 05° 51’48.0”N and longitude 07° 59’32.7”E. The station is dominated by shrubs and herbs and characterized with human activities such as sewage discharge.

Collection of macro-invertebrates

Sampling of macro-invertebrates was carried out during the hours of 8:00 am to 12:00 pm. Macro-invertebrate samples were collected from three (3) sampling stations with sweeping net using kick sampling methods. The sediments were collected in a polythene bag and taken to the laboratory for analysis. The sediments were passed through 3 sieves of 2 mm, 1 mm and 0.5 mm mesh sizes to collect the macro-invertebrates. The macro-invertebrates were poured into a white enamel tray, stained with Rose Benger solution and sorted using...
Diversity Indices

The diversity index for the three Stations is shown in Table 3. Taxa richness or Margalef’s index (d) was highest in Station 1 (2.985) and lowest in Station 3 (1.008). Station 1 had the highest diversity index value of 0.947, while, Station 3 recorded the lowest diversity index value of 0.604. Evenness ranges from 0.337 in Station 3 to 0.362 in Station 2. Margalef’s index (d) and Shannon-Wiener diversity show insignificant difference across station (p>0.05) while evenness show significant difference across stations (p<0.05).

Pollution Tolerance Index (PTI)

PTI was utilized to assess the overall health status of the study area and to ascertain the extent of human impact on the river is shown in Table 4. Unpolluted water would have values between 23 and above as excellent, 17 – 22 as good, while the polluted water would have 11 – 16 as fair and <10 as poor. The PTI values for Stations 2 and 3 were 6 and 4 respectively indicating a poor water quality status.

Discussion

The abundance of macro-invertebrates encountered in the study area was generally low. Ephemeroptera and Zygoptera were poorly represented accounting for 0.82% and 1.44% respectively of the relative abundance. The relative abundance of macro-invertebrates taxa encountered at the different sampling stations is presented in Table 1, while Table 2 shows the percentage composition of macro-invertebrate taxa in the Ediba River.

Figure 1: Map of study area showing the sampling stations.
Table 1: Relative Abundance and Composition of macro-invertebrate communities encountered in Ediba River

Table 1: Relative Abundance and Composition of macro-invertebrate communities encountered in Ediba River
Nigeria and the high abundance of these species is an indication of good water quality. Odonata are known to be facultative species as they are mostly associated with moderately polluted waters and this order was well represented, with the highest diversity of species encountered during the study period. The diversity of Odonata was encountered in Station 1 with species such as; *Trithemis arteriosa*, *Crocothemis erythra*, *Palpopleura pleura* and *Macromia sp.* None were recorded in Station 2 and only *Palpopleura pleura* in Station 3. The high abundance of Odonata in Station 1 maybe due to food availability or habitat preference of this species [19] also reported high abundance of Odonata in Awba Reservoir in Ibadan, Oyo State. Diptera was the second largest taxa after Oligochaetes in relative abundance. Three species of *Helius* sp., *Anopheles sp.* and *Palpamyia sp.* were encountered. *Helius* sp. was encountered in Stations 1 and 2, with 13 and 10 species respectively. *Anopheles sp.* was not recorded in Station 1, but occurred in Stations 2 and 3, with 10 and 11 species respectively. The relative abundance of these taxa has been reported by [20] who showed that conditions such as substrates and the alkaline pH of the water body have favoured their abundance. Lower number of Trichoptera (*Caddis fly*) was recorded, accounting for 2.97% of the relative abundance. According to [21] the larva of caddis fly does not tolerate polluted water, hence the lower number in this study. Hemiptera were fairly represented, with the highest diversity of species encountered in Station 3. The high abundance of Hemiptera and Trichoptera, were encountered, which indicates Oligosaprobic in quality. However, Odonata, Decapoda and Oligochaetes were high in Stations 2 and Station 3, indicating that the waters were relatively polluted or mesosaprobic in quality. The relatively low diversities of Ephemeroptera and Trichoptera as encountered in this study may be due to habitat preference. Trichoptera are mostly present in upland streams or rivers which are well oxygenated when compared to low land fresh waters as encountered in this study.

### Conclusion

Pollution sensitive taxa such as Ephemeroptera and Trichoptera were completely absent in Stations 2 and 3 indicating the poor quality status and the low PTI values in this stations. The need for long-term hydro-biological investigation, with elaborate emphasis on water quality monitoring and the ecology of macro-invertebrate fauna is so much recommended for the safety and conservative use of Ediba River and other fresh water bodies and their resources.
