Ascaris lumbricoides β carbonic anhydrase: a potential target enzyme for treatment of ascariasis

Reza Zolfaghari Emameh1,2,3*, Marianne Kuuslahti1, Daniela Vullo4,5, Harlan R. Barker1, Claudiu T. Supuran4,5 and Seppo Parkkila1,3

Abstract

Background: A parasitic roundworm, Ascaris lumbricoides, is the causative agent of ascariasis, with approximately 760 million cases around the world. Helminthic infections occur with a high prevalence mostly in tropical and developing countries. Therefore, design of affordable broad-spectrum anti-helminthic agents against a variety of pathogens, including not only A. lumbricoides but also hookworms and whipworms, is desirable. Beta carbonic anhydrases (β-CAs) are considered promising targets of novel anthelmintics because these enzymes are present in various parasites, while completely absent in vertebrates.

Methods: In this study, we identified an A. lumbricoides β-CA (AIBCA) protein from protein sequence data using bioinformatics tools. We used computational biology resources and methods (including InterPro, CATH/Gene3D, KEGG, and METACYC) to analyze AlBCA and define potential roles of this enzyme in biological pathways. The AlBCA gene was cloned into pFastBac1, and recombinant AIBCA was produced in sf-9 insect cells. Kinetics of AlBCA were analyzed by a stopped-flow method.

Results: Multiple sequence alignment revealed that AIBCA contains the two sequence motifs, CXDXR and HXXC, typical for β-CAs. Recombinant AIBCA showed significant CA catalytic activity with $k_{cat}$ of $6.0 \times 10^5$ s$^{-1}$ and $k_{cat}/K_m$ of $4.3 \times 10^7$ M$^{-1}$ s$^{-1}$. The classical CA inhibitor, acetazolamide, showed an inhibition constant of 84.1 nM. Computational modeling suggests that the molecular architecture of AIBCA is highly similar to several other known β-CA structures. Functional predictions suggest that AIBCA might play a role in bicarbonate-mediated metabolic pathways, such as gluconeogenesis and removal of metabolically produced cyanate.

Conclusions: These results open new avenues to further investigate the precise functions of β-CAs in parasites and suggest that novel β-CA specific inhibitors should be developed and tested against helminthic diseases.

Keywords: Ascaris lumbricoides, Beta carbonic anhydrase, Enzyme inhibition, Sulfonamide, Acetazolamide, Bioinformatics, Computational biology, Ascariasis

Background

Two parasitic worms, Ascaris lumbricoides and Ascaris suum were independently nominated by Linnaeus in 1758 and Goeze in 1782, respectively. Recent genetic and paleoparasitological evidence has suggested that these strains are, in fact, a single species [1]. Therefore, the original name, A. lumbricoides, should be used upon priority on taxonomic nomination.

remain viable for more than 10 years. Because of the high load of nematodes in ascariasis, there are also severe complications including intestinal obstruction, peritonitis, and acute pancreatitis [3]. There are different treatment strategies for ascariasis, such as surgery (in case of bowel obstruction) and application of anthelmintics drugs including albendazole, mebendazole, and pyrantel pamoate. At present and in the future, access to new broad-spectrum anthelmintics against A. lumbricoides, as well as hookworms and whipworms, are needed in countries where these infections are endemic [4].

Carbonic anhydrases (CAs) have been recently identified as potential targets for novel anti-infective drugs. CAs are encoded by six evolutionary divergent gene families: α, β, γ, δ, ζ, and η CAs [5–7]. All members of these gene families are metalloenzymes, which usually contain zinc ion in their catalytic active site [8]. Certain ζ- and γ-CAs contain cadmium (II), iron (II) or cobalt (II) as alternative metal ion cofactors [9–11]. α-CAs are the most intensively studied members in mammals: cytosolic enzymes (CA I, CA II, CA III, CA VII, and CA XIII), membrane-bound (CA IV, CA IX, CA XII, CA XIV, and CA XV), mitochondrial CAs (VA and CA VB), and secreted CA (VI) [12]. β-CAs are found in plants, algae, fungi, bacteria, protozoans, arthropods, and nematodes [6, 13, 14]; γ-CAs in algae, plants, bacteria, and archaea [15]; δ-CAs in free-living marine dinoflagellates [16]; ζ-CAs in marine diatoms [9]; and η-CAs in Plasmodium parasites [5]. CAs play a critical role in many biochemical pathways, including respiration, pH homeostasis, electrolyte transfer, bone resorption, calcification, gluconeogenesis, lipogenesis, and ureagenesis [12, 17]. Because β-CA genes are absent in vertebrate genomes, while present in many parasite genomes, they are considered potential candidate target enzymes for novel anti-infectives [6, 7, 18, 19]. Literature on CA inhibition reveals that many inhibitors, such as sulfonamide, sulfamides, sulfamates, anions, phenols, coumarins, dithiocarbamates, fullerenes, boronic acids, carboxylates, polyamines, benzamides, hydroxymates, and mercaptans, have been tested against β-CAs to control infectious organisms, such as Candida albicans, Cryptococcus neoformans, Leishmania donovani, Salmonella typhimurium, Porphyromonas gingivalis, Helicobacter pylori, Streptococcus pneumoniae, Mycobacterium tuberculosis, and Brucella suis [20–27]. Meanwhile, inhibitory studies have been also carried out on β-CAs from non-pathogenic model organisms, including Saccharomyces cerevisiae and Drosophila melanogaster [12, 28–34].

In this study, we analyzed properties of A. lumbricoides β-CA (AlBCA) using bioinformatics tools, produced AlBCA as a recombinant protein in insect cells, and tested its kinetic and inhibition properties. These investigations represent the first experimental study on a β-CA protein from a parasitic nematode.

Methods
Identification of AlBCA protein sequence
A β-CA protein sequence from Caenorhabditis elegans (UniProt ID: Q2YS41) [35] was used for the initial NCBI BLAST protein homology search (http://blast.ncbi.nlm.nih.gov/Blast.cgi). Ten nematode β-CA protein sequences, including AlBCA, were aligned with the Clustal Omega algorithm to create a multiple sequence alignment (MSA) within the Jalview program (version 2.8.ob1) (http://www.jalview.org/).

Structural and functional predictions based on AlBCA sequence
The AlBCA protein sequence (UniProt ID: F1F818) was used as a query in the integrative protein signature database, InterPro (http://www.ebi.ac.uk/interpro/). This database integrates together predictive models of representative protein domains, families, and functional sites from multiple and diverse databases, such as Gene3D, PANTHER, Pfram, PIRSF, PRINTS, ProDom, PROSITE, SMART, SUPERFAMILY, and TIGRFAMs [36]. The resulting InterPro ID (IPR001765) for AlBCA protein sequence was used as a query in the CATH/Gen3D database (http://www.cathdb.info/) [37]. This database hierarchically classifies domains into sequence and structure-based families and fold groups, when there is a sufficient evidence for having diverged from a common ancestor. The CATH/Gen3D database generated a rainbow model for superimposed AlBCA protein sequence and several other close species. We also identified the biochemical pathways and interactions of AlBCA through KEGG (Kyoto Encyclopedia of Genes and Genomes) (http://www.kegg.jp/) [38] and METACYC metabolic pathway databases (http://metacyc.org/) [39], which have both been linked to InterPro.

Production of recombinant AlBCA
The CDS sequence of AlBCA gene was retrieved from the EMBL database (http://www.ebi.ac.uk/). GeneArt® gene synthesis technology (Life Technologies) was used to construct the β-CA gene sequence for insertion into the cloning vector (pFastBac1) [40]. DH10Bac cells (which contain the bacmid baculovirus shuttle vector, and a helper plasmid that produces the proteins needed for transposition), were transformed by pFast-AlBCA [7]. Then pFast-AlBCA was purified by PureLink™ HiPure Plasmid Purification Kit (Invitrogen).

Primary transfection of Spodoptera frugiperda (sf-9) insect cells for production of Baculoviruses was performed by HilyMax transfection reagent (Dojindo) (0.5×10⁷ cells/ml in 6-well plates), and the cells were
incubated for 3 days at 29 °C. Cultured cells were centrifuged, passed through a 0.2 μm filter, and stored in a dark tube at +4 °C. For secondary transfection, 20 ml of cultured cells (2×10⁶/ml) were transfected with a primary stock of *Baculoviruses* and incubated for 3 days in a 29 °C shaker. Cultured cells were centrifuged, passed through 0.2 μm filter, and stored in a dark tube at +4 °C. For the expression of recombinant AIBCA, the secondary stocks of *Baculoviruses* were used to infect sf-9 cells (2×10⁶/ml) (using the same procedure as described for the production of the secondary stock, but at higher volumes).

The sf-9 cell culture medium was centrifuged at 5000 RPM for 10 min at room temperature. The supernatant containing secreted AIBCA was diluted at a ratio of 1:5 by binding buffer (0.1 M Tris, 0.2 M Na₂SO₄, pH 8). Then Protino™ Ni-NTA Agarose (Macherey-Nagel) was added to the diluted culture medium and put on a magnetic stirrer with a low rotation speed (2 h at room temperature and overnight incubation at +4 °C without stirring). The culture medium was poured into the funnel filtration system and passed through Whatman® filter paper by vacuum. The flow-through was collected in a separate vial. The agarose was washed with the wash buffer (50 mM Na₂HPO₄, 0.5 M NaCl, 20 mM Imidazol, pH 8). Elution buffer (50 mM Na₂HPO₄, 0.5 M NaCl, 0.25 M Imidazol, pH 8) was added into the column to finally elute the recombinant AIBCA. Thrombin treatment did not cleave the polyhistidine tag in spite of several attempts (data not shown) probably due to the specific molecular folding of AIBCA that completely hid the thrombin cleaving site. Therefore, the kinetic measurements were carried out using recombinant AIBCA containing the polyhistidine tag.

**Kinetic characterization of AIBCA**

An Applied Photophysics stopped-flow instrument has been used for assaying the CA catalyzed CO₂ hydration activity [41]. Phenol red (at a concentration of 0.2 mM) has been used as indicator, working at the absorbance maximum of 557 nm, with 20 mM TRIS (pH 8.3) as buffer, and 20 mM NaClO₄ (for maintaining a constant ionic strength; this anion is not inhibitory against AIBCA up to concentrations of 50 mM, data not shown), following the initial rates of the CA-catalyzed CO₂ hydration reaction for a period of 10–100 s. The CO₂ concentrations ranged from 1.7 to 17 mM for the determination of the kinetic parameters (by Lineweaver-Burk plots) and inhibition constants. For each measurement at least six traces of the initial 5-10% of the reaction have been used for determining the initial velocity. The uncatalyzed rates were determined in the same manner and subtracted from the total observed rates. The inhibition constant of acetazolamide (AAZ, 5-acetamido-1,3,4-thiadiazole-2-sulfonamide) was obtained by non-linear least-squares methods using PRISM 3 and the Cheng-Prusoff equation, as reported earlier [42, 43], and represents the mean from at least three different determinations.

**Results**

**Identification of AIBCA protein sequence**

Multiple sequence alignment (MSA) revealed that all 10 β-CA protein sequences from nematodes contained the first (CXDXR; C: cysteine, D: aspartic acid, R: arginine, X: any residue) and second (HXXC; H: histidine, C: cysteine, X: any residue) highly conserved sequence motifs of the catalytic site, which are the hallmark residues for β-CA enzymes (Table 1, Fig. 1). In addition, the neighbor residues present within or close to the active site were almost identical.

**Structural and functional predictions based on AIBCA sequence**

Analysis of the AIBCA protein sequence by the InterPro database resulted in classification as part of the carbonic anhydrase family InterPro ID IPR001765. In the CATH/Gene3D database, AIBCA is categorized with the CATH superfamily ID 3.40.1050.10 (Beta-carbonic Anhydrase; Chain A). The tools of CATH/Gene3D database were used to generate a rainbow model for superimposition of AIBCA protein with other close relative β-CA proteins (Fig. 2). Metabolic pathway analyses of the AIBCA protein sequence in the KEGG and METACYC databases predict that the enzyme plays a major role in nitrogen metabolism (Fig. 3) and gluconeogenesis pathways (Figs. 4 and 5). Results from the KEGG database suggested that AIBCA might functionally participate in detoxification of cyanate by providing bicarbonate for cyanase enzyme. The METACYC database also predicted

bicarbonate as the final product of the β-CA catalytic reaction. This bicarbonate would be needed for the mitochondrial gluconeogenic pathway where pyruvate is converted to oxaloacetate.

**Production and characterization of recombinant AIBCA**

A β-CA gene insert, including a thrombin cleavage site and a segment encoding a poly-histidine tag, was produced by GeneArt® technology and integrated into a pFastBac1 plasmid (Additional file 1: Figure S1). The purified plasmid was used to produce recombinant AIBCA in sf-9 cells. SDS-PAGE containing the eluted fraction showed three polypeptide bands of 28, 30, and 33 kDa. The 30-kDa band was the major product, which corresponds to the calculated molecular mass of AIBCA (Fig. 6).

**Kinetic properties of AIBCA**

We have measured the kinetic properties of AIBCA for the physiologic reaction of CO₂ hydration to bicarbonate and protons at pH 8.3 where, irrespective if this protein is a type I or type II β-CA, the active site should be open. The Zn (II) ion is coordinated by two Cys and one His residue as well as by a water molecule/hydroxide ion, acting as a nucleophile in the catalyzed reaction.

We compared the activity of the new enzyme with those of well characterized α-class (human CA I and II) and β-CAs from Leishmania donovani chagasi (LdCA), Drosophila melanogaster (DmBCA), and Anopheles gambiae (AgCA), characterized earlier by our group [7, 21, 44]. As displayed in Table 2, AIBCA has significant catalytic activity in the physiologic reaction with the following kinetic parameters: $k_{cat}$ of $6.0 \times 10^5$ s⁻¹ and $k_{cat}/K_m$ of $4.3 \times 10^7$ M⁻¹ s⁻¹. The measured kinetic parameters show that AIBCA has a moderate activity, comparable to that of the relatively slower human carbonic anhydrase isoform hCA I, and in the same range as the enzymes characterized in Anopheles gambiae and Leishmania donovani chagasi [7, 21]. Furthermore, this activity has been effectively inhibited by the sulfonamide compound acetazolamide, which showed an inhibition constant of 84.1 nM. Although this was the only inhibitor investigated so far for this enzyme, work is in progress to understand in detail the inhibitory profiles of the main classes of activity modulators against this enzyme,
The predicted role of AlBCA in nitrogen metabolism pathway. This pathway has been generated by the KEGG (Kyoto Encyclopedia of Genes and Genomes) database. According to this model AlBCA catalyzes the conversion of CO$_2$ and H$_2$O to HCO$_3^-$.

Cyanase converts cyanate to CO and NH in a bicarbonate-dependent reaction.

Role of AlBCA in gluconeogenesis II pathway. The conversion of CO$_2$ to HCO$_3^-$ is catalyzed by β-CA, which is shown with a blue arrow. Bicarbonate is then used for conversion of pyruvate to oxaloacetate.
i.e., anions, sulfonamides and their isosteres, and dithiocarbamates and their isosteres.

**Discussion**

Multiple sequence alignment (MSA) has confirmed the presence of a β-CA enzyme in the proteome of *A. lumbricoides*, an important pathogen which is the causative agent of the parasitic roundworm disease, ascariasis. After this discovery our aim was focused on investigation of the putative functions of this enzyme by bioinformatics prediction tools, production as a recombinant protein, and characterization of its kinetic properties. We determined that AlBCA protein contains the first (CXDXR) and second (HXXC) hallmark sequences of β-CAs, and most of the neighbor residues present within or near the active site of the enzyme were also highly homologous compared to other aligned nine helminthic β-CAs. This result suggested that AlBCA is a catalytically active enzyme. The rainbow model of AlBCA protein was generated by superimposing its nine protein domains with β-CA proteins from close species. α-helices and β-sheets structures showed a high similarity in general domain architecture. We successfully produced recombinant AlBCA protein in Sf-9 insect cells. The SDS-PAGE analysis of the purified recombinant protein showed three polypeptide bands with molecular masses of 28, 30, and 33 kDa. Among them the middle band was clearly strongest and probably represents mature recombinant AlBCA protein. The lower 28-kDa polypeptide band variably appeared in SDS-PAGE analyses, and it probably represents a partially degraded protein. The upper 33-kDa polypeptide might represent a premature form of the enzyme. Even though our previous predictions for subcellular localization did not provide any definitive result [6], the
AIBCA protein is probably either a mitochondrial or secretory protein like the other parasite β-CAs defined so far. Our previous studies have shown that there are examples of metazoan β-CAs in both subcellular locations [6]. Several species, such as Saccoglossus kowalevskii, Trichinella spiralis, and Strigamia maritima, possess mitochondrial β-CAs. The highest score for a secretory signal peptide was predicted to the β-CA of malaria mosquito *Anopheles darlingi*. In our previous analysis using the SignalP server, the β-CA of malaria mosquito *Anopheles darlingi* had the highest score in likelihood to be a secreted protein [6]. In the functional predictions performed by computational tools, AIBCA associated to conversion of CO₂ into bicarbonate, as demonstrated in vitro by stopped-flow kinetic measurements.

Identification of β-CA from *C. elegans* in the Ensembl Metazoa database (http://metazoa.ensembl.org/index.html) revealed that this model nematode contains three full-length β-CA protein sequences (Additional file 2: Table S1). An MSA of these β-CAs with AIBCA sequence, created with the Clustal Omega algorithm (http://www.ebi.ac.uk/Tools/msa/clustalo/) [47], showed that β-C2A (isoform c, Uniprot ID: Q2YS41) from *C. elegans* is most similar to AIBCA. Thus, there is the possibility that the expression pattern of AIBCA is similar to *C. elegans* β-CA2 (isoform c). The expression of *C. elegans* β-CA2 (isoform c, Ensembl gene ID WBGene00013805) in the WormViz expression database (http://www.vanderbilt.edu/wormdoc/wormmap/WormViz.html) of WormBase (https://www.wormbase.org/#01-23-6) [48] showed that β-C2A (isoform c) is expressed in all larval (EE, LE, L1, L2, L3, L4) and adult (including male and hermaphrodites) stages. The highest expression levels were detected in the body wall muscles of L2 stage. The results defined that β-CA is also present in larval neurons, muscles, coelomocytes, hypodermis layer, intestine, and excretory cells. In addition, β-C2A (isoform c) is detectable in the whole body of adult male and hermaphrodite gonads of *C. elegans*. Previously, Fasseas et al. investigated the function of *C. elegans* β-CA using an RNAi technique [35]. They did not find any significant phenotypic change, which might be due to several reasons. First, other CA isoforms might compensate the lack of one β-CA. Second, the efficiency of gene silencing might have been inadequate due to challenges with RNAi technique. In another model organism, *D. melanogaster*, the highest upregulated values of β-CA mRNA were observed in the spermatheca (female), fat body, and heart of adults; as well as early larval stages and late in metamorphosis [7]. The knockdown studies of *D. melagonaster* β-CA showed a clear phenotypic change. Surprisingly, females were sterile and unable to produce eggs. An apparent defect was shown in migration of border cells, which probably contributed to infertility of female *D. melanogaster* [49].

For *in vivo* inhibitory studies, acetazolamide has been tested on live *C. elegans* [50] and *Plasmodium falciparum* (malaria parasite) [51]. These studies showed, however, that acetazolamide could not penetrate through the nematode cuticle or protozoan surface. A BLAST search using 14 human α-CAs as queries recently identified six α-CAs (CAH-1 to 6) in *C. elegans* [52]. Güzel et al. [53] carried out an inhibition study on *C. elegans* CAH-4 and 13 mammalian CAs using other final products, such as aspartate, citrate, and phosphoenolpyruvate through transamination, citric acid cycle, and gluconeogenesis, respectively. Indeed, our results have indicated that AIBCA shows a significant catalytic activity for the conversion of CO₂ into bicarbonate, as demonstrated in vitro by stopped-flow kinetic measurements.

**Table 2**  Kinetic parameters for the CO₂ hydration reaction catalysed by the human isozymes hCA I, II, III, IV, VA, VB, VI, VII, IX, XII, XIII, and XIV (α/CA) and the β-CAs from *Leishmania donovani chagasi* (LdCA), *Drosophila melanogaster* (DmBCA), *Anopheles gambiae* (AgαCA) and *Ascaris lumbricoides* (AIBCA).

different sulfonamide derivatives including 2-(hydrazinocarbonyl)-3-phenyl-1H-indole-5-sulfonamides of type 1 and 2, and compared their inhibition efficacy with traditional CA inhibitors including acetazolamide (AZA) and ethoxzolamide (EZA). Their study defined that some of the new derivatives displayed excellent inhibitory action on CAH-4 with $K_i$ as low as 6 nM, which was 5.83 times better value compared to AZA. Within this context, AZA and EZA showed moderate inhibitory effects on CAH-4. In another study, Giacomotto et al. [52] realized that cah-4 null mutant C. elegans nematodes were nonviable, and knockdown experiments, using the RNAi technique, showed reduced muscle degeneration in dystrophin deficient muscle. Furthermore, cah-4 RNAi treatment caused a significant shift in the dose response curves of CA inhibitors, methazolamide and dichlorphenamide. Giacomotto and co-workers concluded that their studies confirmed the suitability of C. elegans as a model organism for screening, identifying and characterizing potential lead pharmacological agents [52].

Albendazole and Mebendazole are drugs quite well-tolerated when used against ascariasis and resistance has not yet been a major issue. Novel anthelmintic approaches are needed, however, because global healthcare will likely face these challenges at some point, since millions of people require treatment [2, 54]. Inhibition of AIBCA by single dose and broad-spectrum inhibitors, which are effective against various helminthic infections, would be a novel strategy for treatment of ascariasis. It could potentially disrupt the normal detoxification of cyanate, which would in turn increase the intracellular cyanate concentration to a toxic level, leading to the death of the parasite.

Conclusions

β-CAs represent promising targets for novel antiparasitic drug design. In the future, new broad-spectrum, and preferably single dose β-CA inhibitors, should be designed against AIBCA and corresponding enzymes of whipworms and hookworms. For the moment, the clinically used sulfonamide acetazolamide, the only inhibitor tested so far, showed a promising in vitro inhibitory power, with an inhibition constant of 84.1 nM on AIBCA. Acetazolamide’s inability to penetrate the nematode is an obvious problem. Therefore, further studies should be planned to improve the penetration efficacy of CA inhibitors through biological membranes and cuticles of worms. The new sulfonamide derivatives, which were recently shown to inhibit C. elegans α-CAs, could represent useful leads for design of novel compounds having higher efficiency, better penetration, and minimal side effects on human CAs.
