To the Editor,

Today, there are more than 600 antigenic structures among the 30 defined blood groups [1]. The ABO system was first described by Landsteiner in 1900, and remains the most important in the management of tissue and blood transfusion. Indeed, the Rh system has the most important antigen D structure and is the most widely used prior to transfusion [1,2].

It has been shown that the frequency of ABO blood groups differs between populations [1,3]. Determination of the frequency of blood groups in a particular region facilitates timely provision of blood and blood products. There are many studies on the distribution of blood groups in Turkey [4-10]; however, none have considered Kayseri Province, a densely populated city in central Anatolia. As such, the present study aimed to determine the frequency of blood group types in Kayseri Province in order to facilitate to reach the appropriate blood type.

Blood samples obtained from 86,797 individuals that presented to blood banks run by Erciyes University, School of Medicine, State Educational and Research Hospital, between January 2008 and September 2010 were retrospectively analyzed. ABO group types and Rh specificity of the blood samples were determined using a DiaMed-ID Micro Typing System (DiaMed AG, Switzerland) via gel centrifugation. Among the participants, 45,134 (52%) were female and 41,663 (48%) were male. In all, 88.2% (n = 76,580) of the blood samples were Rh-positive and 11.8% (n = 10,217) were Rh negative. The frequency of A, O, B, and AB blood group types was 44% (n = 38,253), 33.3% (n = 28,904), 16.2% (n = 14,031), and 6.5% (n = 5609), respectively. The frequency of ABO and Rh blood groups is shown in Figure 1.

ABO blood groups are determined based on a locus on chromosome 9¾the Rh gene is on the first chromosome [1]. The Rh system is clinically as important as the ABO system because of its role in hemolytic diseases in newborns and in transfusion incompatibility [1]. ABO and Rh blood groups usually exhibit ethnic and regional differences [1,3]. The present findings show that the frequency of A, B, O, and AB blood group types in Kayseri is in accordance with that in the general Turkish population.

In total, 44% of the blood samples analyzed in the present study were blood group A, which is similar to the frequency in other central Anatolian cities, including Konya, Eskişehir, and Ankara [4-6]. The frequency of the O blood group in Turkey is reported to be between 30.8% and 41.2%. In the present study the frequency of the O blood group was 33.3%, which is the same as in the Turkish cities Denizli and Diyarbakır [7,8], and the frequency of the B type blood group in the present study was 16.2%, which is similar to that in Eskişehir.
and Denizli [4,7]. In Turkey the highest frequency of the B blood group is in Şanlıurfa (21.25%) and the lowest frequency is in Malatya (11.4%) [9]. The AB blood group has a frequency in Turkey of 6%-9.2%, which is similar to the 6.5% observed in the present study.

The frequency of Rh-negative individuals varies enormously between ethnic groups. For example, 17% of Brits are Rh negative, versus 0.5% of Japanese; however, the frequency of Rh negative in Turkey is nearly 15%, which is similar to that in Asia and Europe [1,2]. In the present study the Rh positivity rate was 88.2%, whereas other studies conducted in Turkey reported that the Rh positivity rate was 90.8% in Gaziantep, 89% in Malatya, 89.1% in Diyarbakır, and 89.9% in Denizli [8-10].

In conclusion, the frequency of the ABO and Rh blood groups observed in Kayseri Province in the present study differs from that in other Turkish cities, but is similar to that in the general Turkish population. This could be due to the fact that Kayseri Province is located in the center of Turkey. In recent years Kayseri has experienced the influx of a high number of migrants coming from other regions of Turkey (especially the south and east) due an increase in the number of industrial jobs. According to Turkish nationwide population statistics (Türkiye İstatistik Kurumu) for 2008-2009, 28,831 people migrated to Kayseri a migration rate of 1.86%. It is critically important that blood banks know the distribution of blood group types in their region. We think that the present study’s findings, as those from studies conducted in other Turkish cities, will contribute to the Turkish blood type database and, most importantly, will facilitate easy access to appropriate blood types, as needed.
