Since January 2020 Elsevier has created a COVID-19 resource centre with free information in English and Mandarin on the novel coronavirus COVID-19. The COVID-19 resource centre is hosted on Elsevier Connect, the company's public news and information website.

Elsevier hereby grants permission to make all its COVID-19-related research that is available on the COVID-19 resource centre - including this research content - immediately available in PubMed Central and other publicly funded repositories, such as the WHO COVID database with rights for unrestricted research re-use and analyses in any form or by any means with acknowledgement of the original source. These permissions are granted for free by Elsevier for as long as the COVID-19 resource centre remains active.
Short communication

Fulminant myocarditis and systemic hyperinflammation temporally associated with BNT162b2 mRNA COVID-19 vaccination in two patients

Immune-mediated myocardial injury following Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV2) infection has been described in adults and children. Cases of myocarditis following immunization for SARS-CoV2 have recently been documented, mostly associated with mild severity and spontaneous recovery. We herein report two cases of fulminant myocarditis following BNT162b2 mRNA Covid-19 vaccination associated with systemic hyperinflammatory syndrome and refractory shock requiring support with veno-arterial extracorporeal membrane oxygenation.

Immune-mediated myocardial injury following Severe Acute Respiratory Syndrome Coronavirus-2 (SARS-CoV2) infection has been described in adults and children [1,2]. Cases of myocarditis following immunization for SARS-CoV2 have recently been documented [3–8]. We herein report two cases of fulminant myocarditis following BNT162b2 mRNA Covid-19 vaccination the show unique features of systemic hyperinflammation, already described in young males affected by Covid-19 [9]. The cases were reported to the Vaccine Adverse Event Reporting System of the Food & Drug Administration of the United States of America. Informed consent was provided by the next of kin.

A 27-year-old male with trisomy 21 complicated by speech impairment without history of cardiovascular disease presented in cardionic shock 2 days after his second vaccine dose. He had received the first dose without adverse effects. Approximately 36 h after the second dose, he developed nausea and vomiting. He presented to another hospital in shock (blood pressure 77/54 mmHg and heart rate 133/min) and found to have diffuse ST segment elevation in electrocardiogram (Fig. 1). Cardiac catheterization showed no coronary obstructions. Initially, creatine kinase myocardial band level (CK-MB) was 252 ng/mL (normal value [NV] < 5). Transthoracic echocardiogram showed severe left ventricular systolic dysfunction (LVEF 20%) and a small circumferential pericardial effusion without tamponade. A diagnosis of presumed fulminant pericarditis was made and methylprednisolone 1000 mg and human immunoglobulin (IVIG) 60 g were given. The course was complicated by hemodynamically unstable ventricular tachycardia refractory to electrical cardioversion followed by pulseless electrical activity. He was resuscitated with veno-arterial extracorporeal mechanical oxygenation (VA-ECMO). After return of circulation, he was supported by multiple vasopressors, mechanical ventilation, and renal replacement therapy (RRT). Despite these interventions, multiorgan failure and re-fractory shock persisted. Lactic acid increased from 6 to 28 mmol/L (NV < 2), D-dimer increased from 4.21 to >20 μg/mL (critically high > 5.0), INR increased from 2.0 to 10.0, and fibrinogen dropped to 100 mg/dL. C-reactive protein (CRP) and ferritin were highly elevated on admission 20 μg/mL (critically high > 5.0), INR increased from 2.0 to 10.0, and fibrinogen dropped to 100 mg/dL. C-reactive protein (CRP) and ferritin were highly elevated on admission 13.1 mg/dL (NV < 0.5) and 23,000 ng/mL, respectively, leading to a decision to administer anakinra (Kineret®). Interleukin-6 level eventually came back highly elevated at 333 pg/mL (NV < 13). Thrombocytopenia developed progressively from 223 × 109/L to 21 × 109/L, while hemoglobin decreased from 11.5 to 8.7 g/dL. The patient demonstrated acute liver injury (ALI) with alanine transferase (ALT) 801 U/L and aspartate transaminase (AST) for SARS-CoV2 and other common respiratory viruses more

and hyperinflammatory syndrome: (A) The ECG of patient #1 shows diffuse ST segment elevations in a ‘shark fin’ pattern that is classically associated with unfavorable prognosis. (B) The ECG of patient #2 shows sinus tachycardia and non-specific abnormalities of the repolarization.

frequently associated with myocarditis was negative. SARS-CoV2 spike protein IgG antibody was positive (62.8 arbitrary units/ml [NV <15.0]), and anti-nucleocapsid IgG was negative, consistent with immunization status. Approximately 21 h after admission, patient died due to recurrent cardiac arrest and refractory shock. Family declined request for autopsy.

A 34-year-old female without prior medical history presented 9 days after her first vaccine dose. On day 4 after vaccine, she developed fevers, cough, chest pain, nausea, and vomiting. She presented to another institution with hypotension and sinus tachycardia, an echocardiogram showed severely reduced LVEF of 15%. Cardiac catheterization at the same time showed preservation of cardiac output and normal filling pressures. A cardiac magnetic resonance, performed 45 days after the initial presentation, showed LVEF of 35%, diffuse elevation of native T1 values, small pericardial effusion with enhancement of the pericardium anterior and anterolaterally and small patchy areas of enhancement following delayed imaging after gadolinium in the mid-wall of the anterior wall, consistent with myopericarditis. Genetic testing for 121 genes (Invitae, San Francisco, CA, USA) showed no variants associated with genetic disorders. Guideline-directed heart failure treatment was also initiated. She was discharged from the hospital after 73 days.

In summary, both cases presented features of fulminant myocarditis with a temporal association with the BNT162b2 mRNA Covid-19 vaccination, in absence of other apparent causes, and with unique features of systemic hyperinflammation associated with refractory shock.

Several reports in the past months had suggested a possible association between the BNT162b2 mRNA Covid-19 and myocarditis [3–8], and the Center for the Disease Control (CDC) in the United States of America has now acknowledged an increased risk of myocarditis, especially in young adults [10]. An excess in number of cases after the second injection, as compared with the first injection, in young adults has been noted [10]. The severity of the cases reported so far have been, for the most part, rather mild [8,10]. The CDC report of 12 July 2021 identified 633 reports of myocarditis and pericarditis with a very small number being critical requiring intensive care [10].

The CDC report also recommends that despite a higher risk of vaccine associated myocarditis, Covid-19 vaccination appears to be overall associated with significantly less adverse outcomes than Covid-19 infection among all age groups [10]. The rapid presentation of the two cases presented herein and the evolution into multigorgan failure and refractory shock are therefore highly unusual and reflects the fact the fulminant myocarditis can present as part of a systemic hyperinflammatory syndrome, as seen in patients with Covid-19 [9], and it is associated with grave prognosis and death. These cases identify the need for awareness of a potential, albeit extremely rare, link of BNT162b2 mRNA Covid-19 vaccination associated with fulminant myocarditis as part of a severe systemic hyperinflammatory syndrome, requiring mechanical cardiac support and, most importantly, immunosuppressive therapy. The degree of the inflammatory biomarkers and multigorgan dysfunction seen in the two cases described, as in some patients with Covid-19, is indeed out of proportion to with hemodynamic failure and shock and it is not rapidly resolved by cardiac mechanical support, reflecting a significant degree of vasoplegia. The optimal immunosuppressive treatment for systemic hyperinflammation associated with fulminant myocarditis is unknown [11]. We chose a combination of high dose methylprednisolone, IVIG and anakinra (Table 1) as a strategy used across a variety of immunologic and rheumatologic diseases characterized with inappropriate macrophage activation.
Table 1

Key biomarkers at admission and immunomodulating therapy.

| Presentation          | Patient #1                                      | Patient #2                                      |
|-----------------------|-------------------------------------------------|-------------------------------------------------|
| Symptoms              | Nausea and vomiting                             | Fever, cough, chest pain, nausea and vomiting   |
| Vaccine type          | BNT162b2 mRNA Covid-19                         | BNT162b2 mRNA Covid-19                         |
| Timing                | 2 days after 2nd dose                           | 9 days after 1st dose                           |
| Hemodynamics          | Hypotension and tachycardia                     | Hypotension and tachycardia                     |
| ECG                   | ST segment elevation                            | Non-specific changes                            |
| Echocardiogram        | LVEF 20%                                        | LVEF 15%                                        |
| CRP                   | 13.1 mg/dl                                      | 5.6 mg/dl                                      |
| Interleukin-6         | 333 pg/ml                                       | 17.2 pg/ml [12 h after therapy]                |
| Ferritin              | 23,000 ng/ml                                    | >30,000 ng/ml                                  |
| INR                   | 2.0                                             | 4.5                                            |
| D-dimer               | 4.21 μg/ml                                      | >20 μg/ml                                      |
| Lactic acid           | 6 mmol/l                                        | 13 mmol/l                                      |
| CK-MB                 | 252 ng/ml                                       | 42 ng/ml                                       |
| SARS-CoV2 spike IgG   | 62.8 a.u./ml                                    | 64 a.u./ml                                     |
| SARS-CoV2 NC IgG      | negative                                        | negative                                       |

**Immunosuppressive Therapy**

| Methylprednisolone    | 1000 mg                                         | 1000 mg daily for 3 days, followed by a slow prednisone taper over several weeks |
| Anakinra              | 60 mg                                           | 30 mg daily for 4 days                                                              |
| Outcomes              | 100 mg (2 doses)                                | 100 mg daily                                                                     |
|                       | Deceased 21 h after admission                   | Recovering, minimal symptoms, LVEF 35%, delayed enhancement after gadolinium at cardiac magnetic resonance; discharged from the hospital after 73 days |

**Abnormalities:** a.u. = arbitrary units; CRP = C reactive protein; CK-MB = creatine kinase myocardial band; IgG = Immunoglobulin G; INR = International normalized ratio; SARS-CoV2 = Severe Acute Respiratory Distress Syndrome Coronavirus-2.
