Negative thermal expansion triggered anomalous thermal upconversion luminescence behaviors in Er$^{3+}$/Yb$^{3+}$-codoped Y$_2$Mo$_3$O$_{12}$ microparticles for highly sensitive thermometry†

Huocheng Lv, Peng Du, Laihui Luo and Weiping Li

For the sake of overcoming the challenges of optical thermometers with high sensitivity, we designed Er$^{3+}$/Yb$^{3+}$-codoped Y$_2$Mo$_3$O$_{12}$ microparticles with thermally enhanced upconversion (UC) emission. Excited at 980 nm, the impact of the Yb$^{3+}$ ion content on the UC emission properties of the prepared samples is studied. It is found that the optimal doping content for Yb$^{3+}$ ions in the Y$_2$Mo$_3$O$_{12}$ host is 13 mol% and the involved UC mechanism pertains to the two-photon excitation process. As the temperature increases from 303 to 583 K, an enhancement in the UC emission intensity is seen triggered by the NTE effect. Furthermore, via use of the fluorescence intensity rate, the thermometric behaviors of the Y$_2$Mo$_3$O$_{12}$:Er$^{3+}$/0.22Yb$^{3+}$ microparticles are explored, in which their maximum absolute and relative sensitivities are 6.79% K$^{-1}$ and 0.79% K$^{-1}$, respectively. Additionally, in comparison with those of the Y$_2$Mo$_3$O$_{12}$:Er$^{3+}$/0.22Yb$^{3+}$ microparticles, Y$_2$Mo$_3$O$_{12}$:Er$^{3+}$/0.22Yb$^{3+}$@BiOF:Tm$^{3+}$/Yb$^{3+}$ composites exhibit superior thermometric properties with high absolute and relative sensitivities of 16.89% K$^{-1}$ and 1.09% K$^{-1}$, respectively. As Y$_2$Mo$_3$O$_{12}$ compounds have NTE properties and high thermal stability, our findings may inspire new insight into developing thermally enhanced upconversion materials for highly sensitive thermometry.

1. Introduction

Upconversion (UC) emission via the use of rare-earth ion doped luminescent materials is regarded as a feasible strategy to realize versatile applications in many aspects, such as high-resolution bioimaging, light-emitting diodes, optical thermometry, pollutant degradation, etc. In particular, the utilization of UC emission to implement optical thermometry has attracted considerable attention owing to its satisfactory features (e.g., rapid response, high spatial resolution, non-contact readout, etc.) in comparison with those of traditional thermometers. Currently, the fluorescence intensity rate (FIR), which makes use of the temperature-dependent emission intensities of thermally coupled levels (TCLs) of rare-earth ions, has been greatly researched for optical thermometry. In terms of the TCLs, their energy band gap ($\Delta E$) should be within a certain range of 200–2000 cm$^{-1}$, which is not of benefit for achieving high relative sensitivity ($i.e., S_r \propto \Delta E/kT^2$). Thus, a new technique, which takes advantage of the temperature-dependent FIR value of two emitting centers, was proposed to circumvent this issue. Since the emission of Er$^{3+}$ and Nd$^{3+}$ ions exhibited different temperature dependence, Dong et al. found that the absolute sensitivity (i.e., $S_a$) of NaYF$_4$:Er$^{3+}$/Nd$^{3+}$/Yb$^{3+}$ UC nanocrystals was 8.9% K$^{-1}$ and it was higher than that of reported optical thermometers based on TCLs. Also, utilizing the temperature-dependent emission of Er$^{3+}$ and Tm$^{3+}$ ions, Xu et al. reported that the maximum $S_a$ value of Y$_2$O$_3$:Er$^{3+}$/Tm$^{3+}$/Yb$^{3+}$ nanoparticles was 1.12% K$^{-1}$. In spite of these achievements, the implementation of optical thermometry by using UC emission is still hindered by some inherent limitations of upconversion materials, such as weak and impressionless emission. For example, thermal quenching (i.e., loss of the emission at elevated temperature) generally exists in upconversion materials, which greatly restricts the feasibility of UC emission. Consequently, some facile and available strategies should be proposed to figure out this shortage.

Recently, the interest in negative thermal expansion (NTE) materials, whose unit cell volumes decrease as the temperature increases, is increasing owing to their scientific curiosity (e.g., the mechanism behind the NTE) and practical applications (e.g., adjusting the thermal expansion coefficient). Among NTE compounds, A$_2$Mo$_3$O$_{12}$ (A represents a trivalent cation) has...
received extensive attention on account of its merits of large chemical flexibility, stable structure, high ion conduction and strong NTE performance.\textsuperscript{16,17} Especially, \(Y_2Mo_3O_{12}\) shows the best NTE behaviors with lowest anisotropy since the \(Y^{3+}\) ions possess a relatively bigger ionic radius and smaller electronegativity in comparison with other trivalent cations,\textsuperscript{18,19} and thus it has been widely researched as a host material. Interestingly, Wang \textit{et al.} revealed that the NTE effect in \(Yb_2W_2O_{12}\) and \(Sc_2Mo_3O_{12}\) compounds was of benefit for thermally enhancing the UC emission of rare-earth ions (i.e., \(Er^{3+}, Ho^{3+}\), and \(Tm^{3+}\)) due to the lattice distortion and contraction.\textsuperscript{20,21} These results provide an idea that thermally enhanced UC emission is expected to be realized in rare-earth ion doped NTE materials. Nevertheless, the investigation on the thermal enhancement of UC emission as well as its corresponding mechanism in rare-earth ion doped NTE compounds is still not sufficient.

Inspired by this, we selected the \(Er^{3+}\) ion as the activator because of its intense green emission originating from the TQLs of \(2H_{11/2}\) and \(4S_{3/2}\), whereas the \(Yb^{3+}\) ion was employed as the sensitizer since it can capture near-infrared light efficiently and transfer the energy to \(Er^{3+}\) ions.\textsuperscript{22,23} With the aid of sol–gel reaction technology, a series of \(Er^{3+}/Yb^{3+}\)-codoped \(Y_2Mo_3O_{12}\) upconverting microparticles were synthesized. The phase structure, morphology and UC emission features of the developed compounds were studied in detail. Furthermore, the NTE effect triggered thermal enhancement of UC emission in the resultant samples was also explored. \textit{Via} the utilization of the FIR technique to analyze the temperature-dependent emission intensities of TCLs, the thermometric properties of the synthesized microparticles in the temperature range of 303–583 K were investigated. Ultimately, to further improve the temperature sensing capacity of the developed microparticles with NTE behaviors, we constructed a composite in which the negative (i.e., \(Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}\)) and positive (i.e., BiOF: \(Tm^{3+}/Yb^{3+}\)) thermal expansion materials were involved.

2. Experimental

2.1 Synthesis of \(Er^{3+}/Yb^{3+}\)-codoped \(Y_2Mo_3O_{12}\) microparticles

The sol–gel reaction technique was applied to prepare the \(Y_{3-0.01-x}Mo_{x}O_{12}:0.02Er^{3+}/2xYb^{3+}\) (abbreviated as \(Y_2Mo_3O_{12}:Er^{3+}/2Yb^{3+}\); \(0 \leq x \leq 0.16\)) compounds. Notably, the \(x\) value stands for the molar ratio. High purity powders including \((NH_4)_6Mo_7O_{24}\cdot4H_2O, Er(NO_3)_3\cdot5H_2O, Y(NO_3)_3\cdot6H_2O, Yb(NO_3)_3\cdot5H_2O\) and citric acid were used as starting materials. Briefly, \(Y(NO_3)_3\cdot6H_2O\) ([1.98 – 2x] mmol), \(Er(NO_3)_3\cdot5H_2O\) (0.02 mmol), \(Yb(NO_3)_3\cdot5H_2O\) (2x mmol) and \((NH_4)_6Mo_7O_{24}\cdot4H_2O\) (0.143 mmol) were weighed and put into a beaker which contained 200 mL of deionized water. Then, 10 mmol of citric acid was added into the above solution under strong mechanical stirring. After that, the beaker was sealed and the temperature was boosted to 80 °C. After stirring for 30 min, the lid was shifted and it was heated at 80 °C for 12 h to remove the water, leading to the generation of a wet-gel. Afterwards, we transferred it to an oven and kept it at 120 °C for another 12 h to form the xerogel. Lastly, the xerogel was sintered at 800 °C for 6 h in a furnace to form the final products.

2.2 Synthesis of \(Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}@\text{BiOF}:Tm^{3+}/Yb^{3+}\) composites

The \(Bi_{0.14}OF:0.01Tm^{3+}/0.05Yb^{3+}\) (BiOF: \(Tm^{3+}/Yb^{3+}\)) positive thermal expansion phosphors were prepared by a solid-state reaction method. Powders including \(Bi_2O_3, NH_4F, Er_2O_3\) and \(Yb_2O_3\) were employed as the raw materials. Proper amounts of these above powders were weighed and mixed adequately by means of an agate mortar. Then, this mixture was kept in a crucible and sintered at 500 °C for 3 h to achieve the BiOF: \(Tm^{3+}/Yb^{3+}\) phosphors. After that, a typical self-assembly method was adopted to prepare the \(Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}@\text{BiOF}:Tm^{3+}/Yb^{3+}\) composites. In brief, proper amounts of BiOF: \(Tm^{3+}/Yb^{3+}\) and \(Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}\) microparticles (i.e., mass rate = 1:5) were weighed and added into ethanol (30 mL). After stirring for 2 h, the mixture was heated at 80 °C to remove the ethanol, leading to the formation of the \(Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}@\text{BiOF}:Tm^{3+}/Yb^{3+}\) composites.

2.3 Sample characterization

The crystal structure and crystallinity of the final products were checked using an X-ray diffractometer (Bruker D8 Advance; Cu Kz radiation). The elemental composition and morphology of the samples were measured \textit{via} a field-emission scanning electron microscope (FE-SEM; HITACHI SU3500) equipped with an energy-dispersive X-ray spectroscopy (EDS) accessory. The surface properties and thermal stability of the resultant microparticles were examined by using a Fourier transform infrared (FT-IR) spectrophotometer (Bruker Tensor 27) and differential scanning calorimetry and thermogravimetric analysis (DSC–TG) device (SDTQ 600), respectively. An ultraviolet-visible (UV-vis) spectrophotometer (Cary 500) was adopted to record the diffuse reflectance spectrum. The UC emission spectra of the studied samples were detected \textit{via} a fluorescence spectrometer (Edinburgh FSS) with a temperature control system (Linkam HFS600E-PB2) attached.

3. Results and discussion

3.1 Phase structure and microstructure behaviors

The impact of the doping content on the phase compositions of the final products is verified by utilizing X-ray diffraction (XRD). Fig. 1(a) shows the XRD profiles of the \(Y_2Mo_3O_{12}:Er^{3+}/2Yb^{3+}\) microparticles. As illustrated, when the \(Yb^{3+}\) ion content is low (i.e., \(x \leq 0.11\)), these recorded diffraction peaks are able to be primarily indexed by the standard orthorhombic \(Y_2Mo_3O_{12}\) (JCPDS \#28-1541), revealing that the designed \(Er^{3+}/Yb^{3+}\)-codoped \(Y_2Mo_3O_{12}\) compounds are successfully synthesized by means of the sol–gel reaction technique. Nevertheless, two tiny peaks from the impurity phase of \(Y_2Mo_3O_{15}\) (JCPDS \#53-0358) are detected in the XRD profiles when the doping content is over 11 mol% (i.e., \(x = 0.11\)), as shown in Fig. 1(a), suggesting that the \(Yb^{3+}\) ions present a solubility limitation in the selected host lattices. In order to understand the crystal structure of the studied samples in depth, the Rietveld XRD refinements of the \(Y_2Mo_3O_{12}:Er^{3+}\) and \(Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}\) microparticles are
performed and the corresponding results are depicted in Fig. 1(b and c), respectively. The refinement results imply that the prepared samples have a pure orthorhombic phase with the Pbcn space group. Furthermore, the lattice constants of the $Y_2Mo_3O_{12}:Er^{3+}/xYb^{3+}$ ($x = 0$ and 0.11) microparticles are demonstrated to be smaller, which are assigned to the different ionic radii between the $Y^{3+}$ ions and dopants (i.e., $Mo^{6+}$, $O^{2-}$, $Er^{3+}$, $Yb^{3+}$), than those of $Y_2Mo_3O_{12}$ (see Table S1, ESI†). The existence of $Y$, $Mo$, $O$, $Er$, and $Yb$ in the studied compounds, as shown in Fig. S5(a) (ESI†), further confirming the formation of the $Er^{3+}/Yb^{3+}$-codoped $Y_2Mo_3O_{12}$ compounds.

As shown in Fig. S1 (ESI†), the spatial structure of the $Y_2Mo_3O_{12}$ unit cell is drawn and shown in Fig. 1(d). Evidently, $Y_2Mo_3O_{12}$ with an orthorhombic phase consists of corner-shared $MoO_4$ tetrahedrons and $YO_6$ octahedrons, namely, each $YO_6$ octahedron shares its corner with six $MoO_4$ tetrahedrons, while each $MoO_4$ tetrahedron shares its corner with four $YO_6$ octahedrons. Note that this kind of structure is easily rotated at high temperature, leading to the shrinkage of the crystal lattice as well as promoted energy transfer (ET) between the sensitizer and activator.20,21

To shed more light on the stability of the studied samples, the thermogravimetric (TG) spectrum of the $Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}$ microparticles is illustrated in Fig. S2 (ESI†). With elevating the temperature from 300 to 867 K, no significant change is seen in the mass, revealing the excellent thermal stability of the resultant microparticles. The surface performance of the synthesized microparticles is explored by employing the FT-IR spectra, as demonstrated in Fig. S3 (ESI†). Furthermore, the FE-SEM images of the final products reveal the non-uniform morphology of the particles with micron sizes (see Fig. S4, ESI†), in which the shape and size of the particles are insensitive to the doping concentration. Additionally, the compositional analysis based on the EDS spectrum clarifies the existence of $Y$, $Mo$, $O$, $Er$ and $Yb$ in the studied compounds, as shown in Fig. S5(a) (ESI†). The inset shows the CIE coordinate diagram of the $Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}$ microparticles along with their optical image excited at 980 nm.

3.2 UC emission performance of the resultant microparticles

To find the optimal doping content of $Yb^{3+}$ ions in the $Y_2Mo_3O_{12}$ host lattices, the UC emission spectra of the $Y_2Mo_3O_{12}:Er^{3+}/2xYb^{3+}$ microparticles excited at 980 nm were examined and are presented in Fig. 2(a). Clearly, three emission bands with central wavelengths of about 530 nm (i.e., $^4I_{15/2} \rightarrow ^4I_{13/2}$), 553 nm (i.e., $^4S_{3/2} \rightarrow ^4I_{13/2}$) and 661 nm (i.e., $^4F_{9/2} \rightarrow ^4I_{15/2}$) arising from the $Er^{3+}$ ions are observed in the luminescence profiles and their shapes are independent of the doping content except for their intensities.24,25 It is revealed in Fig. 2(b) that both the green and red UC emission intensities are reinforced with the increase of the dopant content and arrive at their maximum values when the $Yb^{3+}$ ion concentration is 13 mol% (i.e., $x = 0.13$), whereas the UC emission intensities start to decline with further elevating the doping concentration due to the energy back transfer from $Er^{3+}$ to $Yb^{3+}$ ions. Notably, from the XRD results, one knows that the developed microparticles doped with 13 mol% $Yb^{3+}$ ions exhibit an impurity phase (see Fig. 1(a)). Thus, to eliminate the influence of the impurity phase on the UC emission and thermometric properties of the studied samples, we selected the $Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}$ microparticles as a representative sample since they not only possess a pure phase structure but also show a relatively intense UC emission intensity.

The Commission International de l’Eclairage (CIE) coordinates of the $Y_2Mo_3O_{12}:Er^{3+}/0.22Yb^{3+}$ microparticles are (0.274, 0.705), (i.e., $Y$, $Mo$, $O$, $Er$, and $Yb$) are distributed equally throughout the whole microparticles (see Fig. S5(b–g), ESI†). The diffuse reflectance spectra data not only prove the existence of $Er^{3+}$ and $Yb^{3+}$ ions in the studied samples, but also reveal that the energy band gap of the final products is independent of the doping concentration, as depicted in Fig. S6 (ESI†).
which are situated in the green region, and it can emit bright green emission upon 980 nm irradiation (see the inset of Fig. 2(b)). In an attempt to expose the NIR-light-induced UC emission mechanism, the pump power dependent UC emission spectra of the Y$_2$Mo$_3$O$_{12}$:Er$^{3+}$/0.22Yb$^{3+}$ microparticles were recorded and are depicted in Fig. 2(c). As revealed, with raising the pump power, a monotonous increment is seen in the emission intensity without altering the luminescence profiles. As proposed in previous literature,$^{24,26}$ the amounts of photons (i.e., $n$) which are needed to populate the high excited levels are able to be estimated by using the function of $I_{UC} \propto P^n$ (herein, $I_{UC}$ and $P$ denote the emission intensity and pump power, respectively). It is evident that the $n$ values of the emission corresponding to the $^2H_{11/2} \rightarrow ^4I_{15/2}$, $^4S_{3/2} \rightarrow ^4I_{15/2}$ and $^4F_{9/2} \rightarrow ^1I_{15/2}$ transitions are 1.74, 1.59 and 1.51 (see Fig. 2(d)), respectively, implying that the above UC emission mechanism is contributed by a two-photon excitation process. Ultimately, the simplified energy level diagram of Er$^{3+}$ and Yb$^{3+}$ as well as the possible luminescence processes is illustrated in Fig. S7 (ESI†).

For the sake of exploring the impact of NTE on the UC emission properties of the final products, the evolution of the luminescence profile as a function of temperature in the 303–583 K range is investigated. When excited at 980 nm, the resultant microparticles emit the featured emission of Er$^{3+}$ ions and the positions are hardly impacted by the temperature, whereas the emission intensities are changed with altering the temperature (Fig. 3(a)). As the temperature is increased from 303 to 583 K, the intensities of all the emission bands are appreciably reinforced, as displayed in Fig. 3(b). Especially, the intensity of green UC emission at 530 nm is enhanced by around 4.4-fold when the temperature is boosted from 303 to 583 K, while those at 553 and 661 nm are boosted by about 1.4-fold and 2.6-fold, respectively. As confirmed in previous literature,$^{18,27}$ one knows that the unit cell volume of the Y$_2$Mo$_3$O$_{12}$ host lattice is reduced with rising temperature, leading to the decline of the distance between the sensitizer (i.e., Yb$^{3+}$) and activator (i.e., Er$^{3+}$). Consequently, the ET from Yb$^{3+}$ to Er$^{3+}$ ions is able to be promoted and more desired excited levels are generated (Fig. 3(c)),$^{20,21}$ resulting in the thermal improvement of the UC emission intensities. Furthermore, the distortion of the host lattices can also contribute to the enhanced UC emission intensity since it can elevate the possibility of the electronic transitions of rare-earth ions.$^{29}$ Owing to these two processes, anomalous thermal UC luminescence behaviors are achieved in Er$^{3+}$/Yb$^{3+}$-codoped Y$_2$Mo$_3$O$_{12}$ microparticles. Notably, the increment rates of the obtained emission are different, which is mainly caused by the features of the TCLs of Er$^{3+}$ ions. In particular, with elevating the temperature, electrons located in the $^4S_{3/2}$ level can be pumped to the $^3H_{11/2}$ level via the thermal activation process. Also, the population of the $^4F_{9/2}$ level from the $^2S_{1/2}$ level can also be impacted by temperature. Thus, the population of the $^3H_{11/2}$, $^1S_{1/2}$ and $^4F_{9/2}$ levels will be different at high temperature, leading to the diverse enhancement rates in their emission intensities. Aside from the promoted UC emission intensity, the color coordinates of the resultant microparticles are also changed from (0.274, 0.705) to (0.228, 0.739) when the temperature is elevated from 303 to 583 K due to the inconsistent responses of the green and red UC emission to temperature, as displayed in Table S2 (ESI†). In addition, with rising temperature, the emitted light becomes brighter and brighter, as demonstrated in the inset of Fig. 3(d), straightforwardly illustrating that the UC emission performance of the rare-earth ions in NTE compounds is able to be promoted via heating.

### 3.3 Thermometric behaviors of the prepared microparticles

As is known, the $^2H_{11/2}$ and $^4S_{3/2}$ levels belong to the TCLs of Er$^{3+}$ ions, which makes Er$^{3+}$ ion based luminescent materials promising candidates for optical thermometry. For the purpose of investigating the thermometric properties of Er$^{3+}$ ions in NET compounds, the normalized temperature-dependent green UC emission spectra of the Y$_2$Mo$_3$O$_{12}$:Er$^{3+}$/0.22Yb$^{3+}$ microparticles are shown in Fig. 4(a). Specifically, the intensity of the $^2H_{11/2} \rightarrow ^4I_{15/2}$ transition is improved compared with that of the $^4S_{3/2} \rightarrow ^1I_{15/2}$ transition when the temperature is increased from 303 to 583 K, resulting in a temperature-dependent FIR value. As disclosed, the FIR value of the emission arising from the $^1H_{11/2} \rightarrow ^1I_{15/2}$ to $^4S_{3/2} \rightarrow ^1I_{15/2}$ transitions is boosted from 0.71 to 2.45 with adjusting the temperature in the 303–583 K range (see Fig. 4(b)). From previous reports,$^{29,30}$ it is obvious that the FIR value of TCLs shows a good exponential relation with temperature (i.e., $T$), as defined below:

$$FIR = \frac{I_U}{I_L} = A \exp(-\Delta E/kT) \tag{1}$$

where $I_U$ and $I_L$ refer to the intensities of emission originating from the upper and lower TCLs, respectively, $A$ is a coefficient, $\Delta E$ is related to the band gap between the TCLs and $k$ denotes the Boltzmann constant. Via the use of eqn (1) to fit the
6.79% K/C0

thermometry.

dFIR

particles are promising luminescent probes for optical

values which are achieved from eqn (1)

Thus, simultaneously taking advantage of the temperature-
dependent UC emission intensities of rare-earth ions in

negative and positive thermal expansion combined materials

be a valid route to ameliorate the thermometric properties

of luminescent materials. As a proof of this guess, we

synthesized Y2Mo3O12:Er3+/0.22Yb3+@BiOF:Tm3+/Yb3+ composites

and explored their thermometric behaviors. Herein, BiOF:Tm3+/Yb3+

phosphors, which can emit intense UC blue emission at 480

arising from the 1G4–3H6 transition of Tm3+ ions, lead to temperature-dependent FIR

emission of Er3+ ions is greatly increased from 2.17 to 16.93 when the temperature is tuned in the 303–583 K range. Notably, the relationship between the temperature and the FIR value of non-TCLs of rare-earth ions is able to be described as follows:34,35

Aside from utilizing the temperature-dependent emission

intensities of TCLs to realize temperature monitoring, another technique, which is based on luminescent compounds with dual-emitting centers, is also intensively adopted. Moreover, it is widely acknowledged that most compounds pertain to positive thermal expansion materials, in which their unit cell volumes are enlarged at elevated temperature, leading to the thermal quenching effect. Obviously, the UC emission performances of the rare-earth ions in positive and negative thermal expansion materials exhibit inverse responses to temperature. Thus, simultaneously taking advantage of the temperature-dependent UC emission intensities of rare-earth ions in negative and positive thermal expansion combined materials would be a valid route to ameliorate the thermometric properties of luminescent materials. As a proof of this guess, we synthesized Y2Mo3O12:Er3+/0.22Yb3+@BiOF:Tm3+/Yb3+ composites and explored their thermometric behaviors. Herein, BiOF:Tm3+/Yb3+ phosphors, which can emit intense UC blue emission at 480 arising from the 1G4–3H6 transition of Tm3+ ions, belong to positive expansion materials and their UC emission intensity gradually decreases with rising temperature (see Fig. S8, ESI†). Upon 980 nm excitation, the UC emission spectra of the designed Y2Mo3O12:Er3+/0.22Yb3+@BiOF:Tm3+/Yb3+ composites as a function of temperature were examined. It is demonstrated in Fig. 5(a) that the intensities of the blue (i.e., Tm3+) and green (i.e., Er3+) emission are dependent on the temperature. In particular, the intensity of Tm3+ ions exhibits a downward trend as the temperature changes from 303 to 583 K, whereas that of the Er3+ ions shows an opposite changing tendency, as illustrated in Fig. S9 (ESI†). Furthermore, from the normalized temperature-dependent UC emission spectra (Fig. 5(b)), one obtains that the green emission intensity of Er3+ ions is sharply enhanced in comparison with that of Tm3+ ions, leading to temperature-dependent FIR values. As disclosed in Fig. 5(c), the FIR value of the blue (i.e., Tm3+) to green (i.e., Er3+) emission is greatly increased from 2.17 to 16.93 when the temperature is tuned in the 303–583 K range. Notably, the relationship between the temperature and the FIR value of non-TCLs of rare-earth ions is able to be described as follows:34,35

Table 1  Comparison of the thermometric properties of developed optical thermometers based on rare-earth ion doped luminescent materials

![Image](https://via.placeholder.com/150)

![Image](https://via.placeholder.com/150)
The temperature-dependent UC emission spectra (normalized at 980 nm) of the Y2Mo3O12:Er3+/0.22Yb3+@BiOF:Tm3+/Yb3+ composites is shown in Fig. S10 (ESI†). Clearly, the FIR values are reversible and repeatable after several cycling heating-cooling processes. To better understand the reversibility of the developed composites, the repeatability (i.e., R) is estimated via the function of $R = 1 - (\max(Q) - Q_i)/Q_i$ (where $Q$ and $Q_i$ refer to the calculated FIR value and its average value, respectively) and its value is found to be as high as 94.5%. In addition, with the aid of the following functions, the temperature uncertainty (i.e., $\Delta T$) of the thermometer via using the developed composites is detected, as defined:44,45

$$\Delta T = \frac{1}{S_r} \frac{\delta F}{FIR}$$

$$\frac{\delta F}{FIR} = \sqrt{\left(\frac{\delta I_1}{I_1}\right)^2 + \left(\frac{\delta I_2}{I_2}\right)^2}$$

where $I_1$ and $I_2$ refer to the emission intensities of Tm$^{3+}$ (blue) and Er$^{3+}$ (green) ions, respectively, and $\delta I_1$ and $\delta I_2$ stand for the errors of $I_1$ and $I_2$, respectively. Consequently, the $\Delta T$ value of the prepared composites is found to be 0.02–0.82 K when the temperature is changed in the range of 303–583 K. These results suggest that the Y2Mo3O12:Er$^{3+}$/0.22Yb$^{3+}$@BiOF:Tm$^{3+}$/Yb$^{3+}$ composites with good reversibility, high sensitivities, and wide operation temperature range are suitable for optical thermometry as temperature-sensing luminescent materials.

4. Conclusion

In summary, a facile sol–gel reaction technique is adopted to prepare Y2Mo3O12:Er$^{3+}$/2xYb$^{3+}$ microparticles. Upon 980 nm excitation, the synthesized samples emit bright UC emission from the Er$^{3+}$ ions and the optimal doping content for the Yb$^{3+}$ ions in the Y2Mo3O12 host lattice is 13 mol%. Owing to the NTE effect, anomalous thermal UC luminescence behaviors are observed in the Er$^{3+}$/Yb$^{3+}$-codoped Y2Mo3O12 microparticles. Through analyzing the temperature-dependent emission of TCLs, the thermometric performances of the Y2Mo3O12:Er$^{3+}$/0.22Yb$^{3+}$ microparticles are estimated, in which the maximum $S_a$ and $S_t$ values are 6.79% K$^{-1}$ and 0.79% K$^{-1}$, respectively. For the purpose of further improving the temperature sensing ability of the luminescent materials, we constructed Y2Mo3O12:Er$^{3+}$/0.22Yb$^{3+}$@BiOF:Tm$^{3+}$/Yb$^{3+}$ composites. Since the UC emission intensities of Tm$^{3+}$ and Er$^{3+}$ ions display opposite temperature dependence, the developed composites possess splendid thermometric properties with high $S_a$ and $S_t$ values of 16.89% K$^{-1}$ and 1.09% K$^{-1}$, respectively. These results demonstrate that the Er$^{3+}$/Yb$^{3+}$-codoped Y2Mo3O12 microparticles are potential candidates for optical thermometry and their

reported rare-earth ion based optical thermometers, but also its $S_a$ value is comparable with other previously developed optical thermometers (see Table 1). Besides, the reversibility of the developed composites is also explored so as to further reveal their feasibility for practical applications. The temperature-triggered switching of the FIR values of the Y2Mo3O12:Er$^{3+}$/0.22Yb$^{3+}$@BiOF:Tm$^{3+}$/Yb$^{3+}$ composites was investigated, as shown in Fig. S10 (ESI†). Clearly, the FIR values are reversible and repeatable after several cycling heating-cooling processes. To better understand the reversibility of the developed composites, the repeatability (i.e., R) is estimated via the function of $R = 1 - (\max(Q) - Q_i)/Q_i$ (where $Q$ and $Q_i$ refer to the calculated FIR value and its average value, respectively) and its value is found to be as high as 94.5%. In addition, with the aid of the following functions, the temperature uncertainty (i.e., $\Delta T$) of the thermometer via using the developed composites is detected, as defined:44,45

$$\Delta T = \frac{1}{S_r} \frac{\delta F}{FIR}$$

$$\frac{\delta F}{FIR} = \sqrt{\left(\frac{\delta I_1}{I_1}\right)^2 + \left(\frac{\delta I_2}{I_2}\right)^2}$$

where $I_1$ and $I_2$ refer to the emission intensities of Tm$^{3+}$ (blue) and Er$^{3+}$ (green) ions, respectively, and $\delta I_1$ and $\delta I_2$ stand for the errors of $I_1$ and $I_2$, respectively.
