An Adaptive Alternating Directions Method of Multipliers

Sedi Bartz * Rubén Campoy † Hung Phan *

March 15, 2021

Abstract

The alternating directions method of multipliers (ADMM) is a powerful splitting algorithm for linearly constrained convex optimization problems. In view of its popularity and applicability, a growing attention is drawn towards the ADMM in nonconvex settings. Recent studies of minimization problems for nonconvex functions include various combinations of assumptions on the objective function including, in particular, a Lipschitz gradient assumption. We consider the case where the objective is the sum of a strongly convex function and a weakly convex function. To this end we present and study an adaptive version of the ADMM which incorporates generalized notions of convexity and varying penalty parameters adapted to the convexity constants of the functions. We prove convergence of the scheme under natural assumptions. To this end we employ the recent adaptive Douglas–Rachford algorithm by revisiting the well known duality relation between the classical ADMM and the Douglas–Rachford splitting algorithm, generalizing this connection to our setting. We illustrate our approach by relating and comparing to alternatives, and by numerical experiments on a signal denoising problem.

1 Introduction

By now, the alternating directions method of multipliers (ADMM) is a well studied and applied splitting algorithm. In particular, it is applied to the problem

\[
\begin{aligned}
\min & \quad f(x) + g(z) \\
\text{s.t.} & \quad Mx = z, \\
x \in \mathbb{R}^n, \quad z \in \mathbb{R}^m;
\end{aligned}
\]

where \( f: \mathbb{R}^n \to \mathbb{R} \) and \( g: \mathbb{R}^m \to \mathbb{R} \) are proper, lower semicontinuous and convex functions, and \( M \in \mathbb{R}^{m \times n} \). The ADMM can be traced back to 1975 in the studies of Glowinski and Marroco [24], and of Gabay and Mercier [21]. It was revisited in the early 1980s in [19, 20]. The ADMM has been successfully applied to a wide range of statistical and learning problems such as sparse regression, signal and image processing, and support vector machines, to name a few. An extensive survey on the ADMM and its applications can be found in [9].

The ADMM can be viewed as an enhanced version of the method of multipliers in the case where the objective function is separable. The augmented Lagrangian associated with (P) is the function

\[
L_\gamma(x, z, y) = f(x) + g(z) + \langle y, Mx - z \rangle + \frac{\gamma}{2} \|Mx - z\|^2,
\]

(1)

where \( \gamma \geq 0 \) is the penalty parameter and \( y \in \mathbb{R}^m \) is the Lagrange multiplier. By employing the method of multipliers one solves (P) by iteratively minimizing \( L_\gamma(x, z, y) \) over the (primal) variables \( x \) and \( z \) while updating the Lagrange multiplier \( y \) (the dual variable). However, this requires to minimize of the Lagrangian jointly in \( x \) and \( z \). In order to avoid this situation, the ADMM takes advantage of the separability of the objective function and splits the minimization procedure into two separate steps, one for each variable. Specifically, by fixing a positive penalty parameter \( \gamma \), the iterative step of the ADDM for solving (P) is

\[
x^{k+1} = \arg\min_{x \in \mathbb{R}^n} L_\gamma(x, z^k, y^k),
\]

(2a)

\[
z^{k+1} = \arg\min_{z \in \mathbb{R}^m} L_\gamma(x^{k+1}, z, y^k),
\]

(2b)

\[
y^{k+1} = y^k + \gamma(Mx^{k+1} - z^{k+1}).
\]

(2c)

Convergence of this scheme is well established in the case where \( f \) and \( g \) are convex, see, e.g., [9, § 3.2]. In nonconvex cases it has been studied, e.g., [26, 28, 38, 39], under various combinations of assumptions which include, in particular, a Lipschitz continuity assumption on the gradient of \( f \) and/or \( g \).

In the present study we consider the case where \( f \) is strongly convex and \( g \) is weakly convex such that the objective of (P) is convex on the constraint. We introduce an adaptive alternating directions method of multipliers (aADMM) for which we incorporate a flexible range of penalty parameters adapted to the convexity constants of the functions \( f \) and \( g \). To this end we revisit the well-known relation between the classical ADMM and the Douglas–Rachford (DR) splitting algorithm [16, 29]. This duality relation was first observed in [20, § 5.1] and later revisited by other authors, see, e.g., [1, Appendix A] or [5, Remark 3.14]. A more detailed discussion regarding the ADMM is available in [18] while [30] is a recent survey on equivalences and other relations between splitting algorithms. We provide an analogous relation between our aADMM and the recent adaptive Douglas–Rachford (aDR) algorithm [3, 15]. We then employ this relation in order to derive convergence of our aADMM from the convergence of the aDR.

We point out (see Remark 4.4) that in our strongly-weakly convex setting, the functions \( f \) and \( g \) in problem (P) can be augmented into convex functions which transform the problem into a convex one, admissible for the classical ADMM, with the same minimizers, optimal values and computational difficulty level. However, the ADMM for the augmented problem corresponds to
a Douglas-Rachford algorithm which is not in direct duality relations with the original strongly-weakly convex problem. Consequently, this theoretical aspect is lacking. Instead, we preserve and analyze the original problem. Our approach does yield a natural duality relation with a corresponding adaptive Douglas-Rachford algorithm which is instrumental in our convergence analysis. An additional benefit of our approach is that we relax and improve previously imposed assumptions on the strongly-weakly convex scenario such as in [31] (see Remark 5.3 and Remark 5.4).

Our main result is Theorem 5.2, where we provide convergence of the ADMM. Moreover, in order to show how our framework generalizes and relaxes the framework of the classical convex ADMM, we incorporate in our convergence analysis the relaxed assumptions regarding the convexity of $f$ and $g$ while not imposing further on top of the traditional constraint qualifications of the ADMM. To this end we revisit and incorporate in our analysis some of the most commonly imposed assumptions and conditions on the classical ADMM. For the sake of accessibility and convenience, we summarize and unify our analysis with these classical conditions into an integrated tool in Corollary 5.6 for the aADMM and, in particular, in Corollary 5.7 for the classical ADMM.

Finally, we illustrate computational aspects of both approaches (our aADMM and the classical ADMM on an equivalent modified problem) by numerical experiments on a signal denoising problem with a weakly convex regularization term.

The remainder of the paper is organized as follows. In Section 2 we recall basic definitions and preliminary results. In Section 3 we recall notions of generalized monotonicity and the convergence of the adaptive Douglas–Rachford algorithm. In Section 4 we introduce our adaptive ADMM, we analyze some of its basic properties and we discuss conditions and constraint qualifications. The convergence of the scheme is established in Section 5. In Section 6 we conduct numerical experiments on a signal denoising problem with a weakly convex regularization term. Finally, we conclude our discussion in Section 7.

## 2 Preliminaries

Throughout, $\langle \cdot, \cdot \rangle$ denotes the inner product in $\mathbb{R}^n$ with induced norm $\| \cdot \|$ defined by $\| x \| = \sqrt{\langle x, x \rangle}$, $x \in \mathbb{R}^n$. We set $\mathbb{R}_+ := \{ r \in \mathbb{R} : r \geq 0 \}$ and $\mathbb{R}_{++} := \{ r \in \mathbb{R} : r > 0 \}$. Let $M \in \mathbb{R}^{m \times n}$. Then $\text{ran} \ M$, $\ker M$ and $\| M \|$ denote, respectively, the range, the null space and the matrix 2-norm of $M$. Let $C \subseteq \mathbb{R}^n$ be a set. The closure, the interior and the relative interior of $C$ are denoted by $\text{cl} \ C$, $\text{int} \ C$ and $\text{ri} \ C$, respectively. We denote by $A : \mathbb{R}^n \to \mathbb{R}^n$ a set-valued operator that maps any point $x \in \mathbb{R}^n$ to a set $A(x) \subseteq \mathbb{R}^n$. In the case where $A$ is single-valued we write $A : \mathbb{R}^n \to \mathbb{R}^n$. The graph, the domain, the range, the set of fixed points and the set of zeros of $A$, are denoted, respectively, by $\text{gra} \ A$, $\text{dom} \ A$, $\text{ran} \ A$, $\text{Fix} \ A$ and $\text{zer} \ A$, i.e.,

$$\text{gra} \ A := \{ (x, u) \in \mathbb{R}^n \times \mathbb{R}^n : u \in A(x) \}, \quad \text{dom} \ A := \{ x \in \mathbb{R}^n : A(x) \neq \emptyset \},$$

$$\text{ran} \ A := \{ x \in \mathbb{R}^n : x \in A(z) \text{ for some } z \in \mathbb{R}^n \},$$

$$\text{Fix} \ A := \{ x \in \mathbb{R}^n : x \in A(x) \} \quad \text{and} \quad \text{zer} \ A := \{ x \in \mathbb{R}^n : 0 \in A(x) \}.$$  

The inverse of $A$, denoted by $A^{-1}$, is the operator defined via its graph by $\text{gra} A^{-1} := \{ (u, x) \in \mathbb{R}^n \times \mathbb{R}^n : u \in A(x) \}$. We denote the identity mapping by $\text{Id}$. The resolvent of the operator
$A : \mathbb{R}^n \rightarrow \mathbb{R}^n$ with parameter $\gamma > 0$ is the operator $J_{\gamma A}$ defined by

$$J_{\gamma A} := (\text{Id} + \gamma A)^{-1}.$$ 

The $\lambda$-relaxed resolvent of $A$ with parameter $\gamma > 0$ is the operator $J_{\gamma A}^{\lambda}$ defined by

$$J_{\gamma A}^{\lambda} := (1 - \lambda) \text{Id} + \lambda J_{\gamma A}.$$ 

**Definition 2.1.** Let $D \subseteq \mathbb{R}^n$ be a nonempty set. The mapping $T : D \rightarrow \mathbb{R}^n$ is said to be

(i) *Lipschitz continuous* with Lipschitz constant $l > 0$ if

$$\|T(x) - T(y)\| \leq l\|x - y\|, \quad \forall x, y \in D;$$

(ii) *nonexpansive* if it is Lipschitz continuous with constant $l = 1$;

(iii) *conically $\theta$-averaged*, where $\theta > 0$, if there exists a nonexpansive mapping $R : D \rightarrow \mathbb{R}^n$ such that

$$T = (1 - \theta)I + \theta R.$$ 

Conically $\theta$-averaged mappings were studied in [7], referred to as *conically nonexpansive mappings*. They can be viewed as a natural extension of the classical $\theta$-averaged mappings (see, e.g., [4, Definition 4.33]). Additional properties and detailed discussions can be found in [3, 23].

An extended real-valued function $f : \mathbb{R}^n \rightarrow ]-\infty, +\infty]$ is said to be *proper* if its (effective) domain, the set $\text{dom} f := \{x \in \mathbb{R}^n : f(x) < +\infty\}$, is nonempty. We say that $f$ is *lower semicontinuous* if, at any $\bar{x} \in \mathbb{R}^n$,

$$f(\bar{x}) \leq \liminf_{x \rightarrow \bar{x}} f(x).$$

Let $\alpha \in \mathbb{R}$. We say that $f$ is $\alpha$-convex if $f - \frac{\alpha}{2}\|\cdot\|^2$ is convex, equivalently, if

$$f((1 - \lambda)x + \lambda y) \leq \lambda f(x) + (1 - \lambda)f(y) - \frac{\alpha}{2}\lambda(1 - \lambda)\|x - y\|^2, \quad \forall x, y \in \mathbb{R}^n, \quad \lambda \in [0, 1].$$

In particular, $f$ is convex if and only if $f$ is 0-convex. If $f$ is $\alpha$-convex, we say that $f$ is *strongly convex* in the case where $\alpha > 0$ and we say that $f$ is *weakly convex* (or *hypoconvex*) in the case where $\alpha < 0$. It follows that if $f_1$ is $\alpha_1$-convex and $f_2$ is $\alpha_2$-convex, then $f_1 + f_2$ is $(\alpha_1 + \alpha_2)$-convex.

The function $f$ is *coercive* if

$$\lim_{\|x\| \rightarrow \infty} f(x) = +\infty$$

and *supercoercive* if

$$\lim_{\|x\| \rightarrow \infty} \frac{f(x)}{\|x\|} = +\infty.$$ 

Then (see, e.g., [4, Corollary 11.17])

$$\text{strong convexity} \implies \text{supercoercivity} \implies \text{coercivity}.$$
Let \( \gamma > 0 \). The proximal operator with parameter \( \gamma \) associated with the function \( f \) is defined by
\[
\text{prox}_{\gamma f} : \mathbb{R}^n \ni y \mapsto \arg\min_{x \in \mathbb{R}^n} \left\{ f(x) + \frac{1}{2\gamma} \| x - y \|^2 \right\}, \quad \forall y \in \mathbb{R}^n.
\]
Let \( x \in \text{dom} \ f \). The (convex) subdifferential of \( f \) at \( x \) is the set
\[
\partial f(x) := \{ u \in \mathbb{R}^n : \langle y - x, u \rangle + f(x) \leq f(y), \quad \forall y \in \mathbb{R}^n \}.
\]

The Fréchet subdifferential of \( f \) at \( x \) is the set
\[
\hat{\partial} f(x) := \left\{ u \in \mathbb{R}^n : \liminf_{y \to x, y \neq x} \frac{f(y) - f(x) - \langle u, y - x \rangle}{\| y - x \|} \geq 0 \right\}.
\]

In the case where \( f \) is differentiable, we denote its gradient at \( x \) by \( \nabla f(x) \). We recall the following facts regarding subdifferentials and gradients.

**Fact 2.2.** Let \( f, g : \mathbb{R}^n \to ]-\infty, +\infty] \) be proper and let \( M \in \mathbb{R}^{n \times m} \).

(i) If \( f \) is convex, then \( \hat{\partial} f(x) = \partial f(x) \) for all \( x \in \text{dom} \ f \).

(ii) If \( f \) is differentiable at \( x \in \text{dom} \ f \), then \( \hat{\partial} f(x) = \{ \nabla f(x) \} \).

(iii) \( 0 \in \hat{\partial} f(\bar{x}) \) if and only if \( \bar{x} \in \text{dom} \ f \) minimizes \( f \) over \( \mathbb{R}^n \).

(iv) \( 0 \in \hat{\partial} f(\bar{x}) \) if \( f \) attains a local minimum at \( \bar{x} \in \text{dom} \ f \).

(v) If \( g \) is differentiable at \( x \in \text{dom} \ f \cap \text{dom} \ g \), then \( \hat{\partial} (f + g)(x) = \hat{\partial} f(x) + \nabla g(x) \).

(vi) If \( f \) and \( g \) are lower semicontinuous, then
\[
\hat{\partial} f(x) + \hat{\partial} g(x) \subseteq \hat{\partial} (f + g)(x) \quad \text{for all} \quad x \in \text{dom} \ f \cap \text{dom} \ g.
\]

(vii) If \( f \) is lower semicontinuous, then
\[
M^T \hat{\partial} f(Mx) \subseteq \hat{\partial} (f \circ M)(x) \quad \text{for all} \quad x \in \mathbb{R}^n \text{ such that } Mx \in \text{dom} \ f.
\]

**Proof.** (i): See, e.g., [33, Proposition 8.12]. (ii): See, e.g., [27, Proposition 1.1]. (iii): See, e.g., [4, Theorem 16.3]. (iv): See, e.g., [27, Proposition 1.10]. (v): See, e.g., [27, Corollary 1.12.2]. (vi): See, e.g. [33, Corollary 10.9]. (vii): See, e.g. [33, Theorem 10.6].

In order to carry out our analysis we adopt the Fréchet subdifferential. However, our approach is applicable if one adopts any of several other notions of the subdifferentials, such as the Mordukhovich subdifferential or the Clarke-Rockafellar subdifferential since these notions coincide for \( \alpha \)-convex functions (see [7, Proposition 6.3]).

Finally, let \( f, g : \mathbb{R}^n \to ]-\infty, +\infty] \) be proper and convex. We recall that the recession function of \( f \) is defined by
\[
\text{rec} \ f : \mathbb{R}^n \to ]-\infty, +\infty] : y \mapsto \sup_{x \in \text{dom} \ f} \{ f(x + y) - f(x) \},
\]
the Fenchel conjugate of $f$ is defined by

$$f^* : \mathbb{R}^n \to ]-\infty, +\infty] : u \mapsto \sup_{x \in \mathbb{R}^n} \{ \langle u, x \rangle - f(x) \},$$

and the infimal convolution of $f$ and $g$ is defined by

$$f \square g : \mathbb{R}^n \to ]-\infty, +\infty] : x \mapsto \inf_{y \in \mathbb{R}^n} \{ f(y) + g(x - y) \}.$$

3 Generalized monotonicity and the adaptive Douglas-Rachford algorithm

We recall the following notions of generalized monotonicity.

**Definition 3.1.** Let $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ and let $\alpha \in \mathbb{R}$. Then $A$ is said to be

(i) \textit{$\alpha$-monotone} if

$$\langle x - y, u - v \rangle \geq \alpha \|x - y\|^2, \quad \forall (x, u), (y, v) \in \text{gra} A;$$

(ii) \textit{$\alpha$-comonotone} if $A^{-1}$ is $\alpha$-monotone, i.e.,

$$\langle x - y, u - v \rangle \geq \alpha \|u - v\|^2, \quad \forall (x, u), (y, v) \in \text{gra} A.$$

An $\alpha$-monotone (resp. $\alpha$-comonotone) operator $A$ is said to be \textit{maximally $\alpha$-monotone} (resp. \textit{maximally $\alpha$-comonotone}) if there is no $\alpha$-monotone (resp. $\alpha$-comonotone) operator $B : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ such that $\text{gra} A$ is properly contained in $\text{gra} B$.

**Remark 3.2.** We note that in the case where $\alpha = 0$ in Definition 3.1, both 0-monotonicity and 0-comonotonicity simply mean \textit{monotonicity} (see, for example, [4, Definition 20.1]). In the case where $\alpha > 0$, $\alpha$-monotonicity is also referred to as \textit{strong monotonicity} (see, e.g., [4, Definition 22.1(iv)]) and $\alpha$-comonotonicity is also referred to as \textit{cocoercivity} (see, e.g., [4, Definition 4.10(iv)]). In the case where $\alpha < 0$, $\alpha$-monotonicity is also referred to as \textit{hypomonotonicity} (or \textit{weak monotonicity}) and $\alpha$-comonotonicity is also referred to as \textit{cohypomonotonicity} (see, e.g, [12, Definition 2.2]).

**Fact 3.3 (maximal monotonicity of the subdifferential).** Let $\alpha \in \mathbb{R}$ and suppose that $f : \mathbb{R}^n \to ]-\infty, +\infty]$ is $\alpha$-convex. Then the Fréchet subdifferential of $f$, $\partial f : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$, is maximally $\alpha$-monotone.

**Proof.** See, e.g., [15, Lemma 5.2].

We recall that under certain assumptions on the monotonicity parameters, the resolvents of comonotone operators are conically averaged.

**Fact 3.4 (resolvents of comonotone operators).** Let $\alpha \in \mathbb{R}$ and set $\gamma > 0$ such that $\gamma > -\alpha$. If $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ is $\alpha$-comonotone, then
(i) $J_{\gamma A}$ is single-valued and conically $\frac{\gamma}{2(\gamma + \alpha)}$-averaged;

(ii) $\text{dom} J_{\gamma A} = \mathbb{R}^n$ if and only if $A$ is maximally $\alpha$-comonotone.

Proof. See [3, Propositions 3.7 and 3.8(i)] and [7, Proposition 3.7(v)&(vi)].

**Fact 3.5 (maximal comonotonicity).** Let $\alpha \in \mathbb{R}$ and $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$. The following hold.

(i) $A$ is maximally $\alpha$-comonotone $\iff A^{-1}$ is maximally $\alpha$-monotone.

(ii) Suppose that $\alpha \geq 0$. Then $A$ is maximally $\alpha$-comonotone $\iff A$ is $\alpha$-comonotone and maximally monotone.

Proof. (i): Follows directly from Definition 3.1. (ii): Apply [15, Proposition 3.5(i)] to the operator $A^{-1}$ (alternatively, see [3, Proposition 3.2(ii)]).

**Lemma 3.6 (closedness of graph).** Let $\alpha \in \mathbb{R}$ and let $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be maximally $\alpha$-comonotone. Then $\text{gra} A$ is closed.

Proof. Let $(x_k, u_k)^\infty_{k=0} \subseteq \text{gra} A$ such that $(x_k, u_k) \to (x, u) \in \mathbb{R}^n \times \mathbb{R}^n$. By employing Fact 3.5(i), we see that $A^{-1}$ is maximally $\alpha$-monotone, which is equivalent to $B := A^{-1} - \alpha \text{Id}$ being maximally monotone. Consequently, $\text{gra} B$ is closed (see, for example, [4, Proposition 20.38]). Since $(u_k, x_k - \alpha u_k)^\infty_{k=0} \subseteq \text{gra} B$ and $(u_k, x_k - \alpha u_k) \to (u, x - \alpha u)$, we conclude that $(u, x - \alpha u) \in \text{gra} B$, which, in turn, implies that $(x, u) \in \text{gra} A$.

We conclude this section by recalling the convergence of the adaptive Douglas–Rachford (aDR) algorithm for maximally comonotone operators. The aDR can be viewed as an extension of the classical Douglas–Rachford splitting algorithm [16, 29], originally utilized to find a zero of the sum of two maximally monotone operators by employing their resolvents. The aDR algorithm was recently presented and studied in [15] in order to find a zero of the sum of a strongly monotone operator and a weakly monotone operator. This analysis was later extended in [3] to include, in particular, the case of a strongly comonotone operator and a weakly comonotone operator. Convergence results for the shadow sequence of the aDR (i.e., the image of the aDR sequence under the resolvent) in infinite-dimensional spaces have been recently provided in [2].

We recall the following fact regarding the convergence of the aDR for comonotone operators.

**Fact 3.7 (aDR for comonotone operators).** Let $\alpha, \beta \in \mathbb{R}$ be such that $\alpha + \beta \geq 0$. Let $A : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a maximally $\alpha$-comonotone operator and let $B : \mathbb{R}^n \rightrightarrows \mathbb{R}^n$ be a maximally $\beta$-comonotone operator such that $\text{zer}(A + B) \neq \emptyset$. Suppose that $(\gamma, \delta) \in \mathbb{R}^2_{++}$ satisfy

\begin{align}
0 < \gamma + 2\alpha &= \delta, \quad \text{if } \alpha + \beta = 0, \quad (3a) \\
\text{or } (\gamma + \delta)^2 &= 4(\gamma + \alpha)(\delta + \beta), \quad \text{if } \alpha + \beta > 0; \quad (3b)
\end{align}

and set $(\lambda, \mu) \in \mathbb{R}^2_{++}$ by

\begin{align}
(\lambda - 1)(\mu - 1) &= 1 \quad \text{and} \quad \delta = (\lambda - 1)\gamma. \quad (4)
\end{align}
Set further $\kappa \in ]0, \pi[ \text{ where}$

$$\kappa := \begin{cases} 1, & \text{if } \alpha + \beta = 0; \\ \frac{4(\gamma + \alpha)(\delta + \beta) - (\gamma + \delta)^2}{2(\gamma + \delta)(\alpha + \beta)}, & \text{if } \alpha + \beta > 0. \end{cases} \tag{5}$$

Finally, set $x_0 \in \mathbb{R}^n$ and let $(x_k)_{k=0}^{\infty}$ be generated by the recurrence

$$x_{k+1} = T_{aDR}(x_k) := (1 - \kappa)x_k + \kappa J_{\gamma A} J_{\delta B}^\mu (x_k), \quad k = 0, 1, 2, \ldots \tag{6}$$

Then

(i) $x_k \to x^* \in \text{Fix} T_{aDR} \text{ and } J_{\delta B}(x^*) \in \text{zer}(A + B)$;

(ii) $J_{\delta B}(x_k) \to J_{\delta B}(x^*) \in \text{zer}(A + B)$;

(iii) $J_{\delta B}(x_k) - J_{\gamma A} J_{\delta B}^\mu (x_k) \to 0$.

Proof. We note that (3) implies that $\alpha + \gamma > 0$ and $\delta + \beta > 0$. In view of Fact 3.4, $J_{\gamma A}$ and $J_{\delta B}$ are single-valued with full domain and, consequently, the iteration in (6) is well defined. By [3, Theorem 5.4], we arrive at

$$x_k \to x^* \in \text{Fix} T_{aDR} \text{ and } x_k - T_{aDR}(x_k) \to 0$$

which, combined with [15, Lemma 4.1], implies (i) and (iii). Finally, by invoking Fact 3.4(i) we see that $J_{\delta B}$ is conically averaged. This implies that $J_{\delta B}$ is Lipschitz continuous and, consequently, (ii) follows from (i).  \qed

4 Adaptive ADMM

The adaptive alternating directions method of multipliers requires natural generalized convexity assumptions as well as traditional assumptions on $(P)$. We divide these conditions and constraint qualifications into three categories - generalized convexity assumptions, existence of solutions for $(P)$ and existence and well posedness of our iterative steps. Compared with the traditional framework of the classical ADMM, we show that our settings are more general and admit a wider class of functions within the first category while maintaining traditional assumptions and constraint qualifications in the second and third categories. To this end we recollect the most common and widely imposed conditions on the classical ADMM as well as equivalences and relations between them. We divided our discussion into the following subsections: convexity qualifications, critical points and minimizes, introduction of the aADMM, constraint qualifications and related conditions for existence of our iterative steps.

4.1 Convexity assumptions

One of the underlying assumptions for the classical ADMM is that the functions $f$ and $g$ in $(P)$ are proper, lower semicontinuous and convex. We adapt to a wider class of functions via the following natural assumption.
Assumption 4.1. Let $M \in \mathbb{R}^{m \times n}$ be a nonzero matrix. We assume that the function $f : \mathbb{R}^n \to ]-\infty, +\infty]$ is proper, lower semicontinuous and $\alpha$-convex, and $g : \mathbb{R}^m \to ]-\infty, +\infty]$ is proper, lower semicontinuous and $\beta$-convex where $\alpha, \beta \in \mathbb{R}$ are parameters such that
\[
\alpha \geq 0 \quad \text{and} \quad \alpha + \beta \|M\|^2 \geq 0. \]

In order to characterize the solutions of $(P)$ under Assumption 4.1, we will employ the following lemma.

Lemma 4.2. Let $M \in \mathbb{R}^{m \times n}$. Suppose that $g : \mathbb{R}^m \to ]-\infty, +\infty]$ is a $\beta$-convex function where $\beta < 0$. Then $g \circ M$ is $\beta \|M\|^2$-convex.

Proof. Let $x, y \in \mathbb{R}^n$ and $\lambda \in [0, 1]$. Then the $\beta$-convexity of $g$ implies that
\[
(g \circ M)((1 - \lambda)x + \lambda y) = g((1 - \lambda)Mx + \lambda My) \\
\leq (1 - \lambda)g(Mx) + \lambda g(My) - \frac{\beta}{2} \lambda(1 - \lambda)\|Mx - My\|^2 \\
\leq (1 - \lambda)(g \circ M)(x) + \lambda(g \circ M)(y) - \left(\frac{\beta}{2}\|M\|^2\right)\lambda(1 - \lambda)\|x - y\|^2,
\]
i.e., $g \circ M$ is $\beta \|M\|^2$-convex. \hfill \Box

Lemma 4.3. Let Assumption 4.1 hold. Then $(x^*, z^*)$ is a solution of $(P)$ if and only if
\[
Mx^* = z^* \quad \text{and} \quad 0 \in \partial(f + g \circ M)(x^*). \]

Proof. We note that $(P)$ is equivalent to the unconstrained optimization problem of minimizing $f + g \circ M$ over $\mathbb{R}^n$. We claim that $f + g \circ M$ is a convex function. Indeed, under Assumption 4.1, if $\beta \geq 0$, then $f$ as well as $g$ are convex and so is $f + g \circ M$. If $\beta < 0$, then Lemma 4.2 implies that $g \circ M$ is $\beta \|M\|^2$-convex. Consequently, we see that $f + g \circ M$ is $(\alpha + \beta \|M\|^2)$-convex. In particular, $f + g \circ M$ is convex since $\alpha + \beta \|M\|^2 \geq 0$. Finally, by recalling Fact 2.2(iii), we conclude that the minimizers of $(P)$ are characterized by the first order optimality condition $0 \in \partial(f + g \circ M)(x^*)$. \hfill \Box

Remark 4.4 (on strongly-weakly convex settings). Under Assumption 4.1, problem $(P)$ can be referred to as a strongly-weakly convex problem, see, e.g., [15, 25]. Splitting methods for this problem require computability of subdifferentials and their resolvents. We observe that by setting
\[
\tilde{f} := f + \frac{\beta}{2}\|M(\cdot)\|^2 \quad \text{and} \quad \tilde{g} := g - \frac{\beta}{2}\|\cdot\|^2
\]

$(P)$ is equivalent to
\[
\min \left(\tilde{f}(x) + \tilde{g}(z)\right) \quad \text{s.t.} \quad Mx = z. \quad (\tilde{P})
\]

Under Assumption 4.1, both $\tilde{f}$ and $\tilde{g}$ are convex. Indeed, a straightforward verification implies that $\tilde{g}$ is convex. Furthermore, if $\beta \geq 0$, then $\tilde{f}$ is convex because $f$ and $\frac{\beta}{2}\|M(\cdot)\|^2$ are convex. If $\beta < 0$, then $\frac{\beta}{2}\|M(\cdot)\|^2$ is $\beta \|M\|^2$-convex by Lemma 4.2. We note that $f$ is $\alpha$-convex and $\alpha + \beta \|M\|^2 \geq 0$, so $\tilde{f}$ is $(\alpha + \beta \|M\|^2)$-convex, in particular, it is convex.
Consequently, one can apply the classical ADMM to \((\hat{P})\) in order to solve \((P)\) with a similar computational difficulty level. A similar strategy was pointed out as an alternative to the adaptive DR algorithm in [15, Remark 4.15].

We will experiment with the approach outlined in Remark 4.4 in Section 6. However, from the theoretical perspective, we pursue a different path: We do not modify \((P)\), instead, we provide an adaptive version of the ADMM which is admissible under the strongly-weakly convex setting of \((P)\). To this end we provide duality relations with the recent adaptive DR algorithm [15] which, in turn, are instrumental in the proof of convergence of our adaptive scheme. One of the justifications of our approach is that it complements and extends the natural and well known duality relation between the classical ADMM and the classical DR algorithm to the strongly-weakly convex setting. Experiments with our approach and some comparisons to the approach in Remark 4.4 are also included in Section 6. In particular, we highlight the flexibility in the choice of parameters in our aADMM.

4.2 Critical points

We address the issue of critical points and saddle points of the Lagrangian \(L_0\) in (1), as well as their relations to the solutions of \((P)\), under Assumption 4.1.

**Definition 4.5 (critical points).** We say that the tuple \((x^*, z^*, y^*) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) is a critical point of the (unaugmented) Lagrangian \(L_0\) of \((P)\) if

\[-M^Ty^* \in \partial f(x^*), \quad y^* \in \hat{\partial}g(z^*) \quad \text{and} \quad Mx^* - z^* = 0.\]  

We also recall that \((x^*, z^*, y^*)\) is a saddle point of \(L_0\) if

\[L_0(x^*, z^*, y) \leq L_0(x^*, z^*, y^*) \leq L_0(x, z, y^*), \quad \forall (x, z, y) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m.\]

**Lemma 4.6.** Let Assumption 4.1 hold. If \((x^*, z^*, y^*)\) is a critical point of \(L_0\), then \((x^*, z^*)\) is solution of \((P)\).

**Proof.** In view of (7), and by recalling Fact 2.2(vii) and (vi), we see that

\[0 = -M^Ty^* + M^Ty^* \in \partial f(x^*) + M^T\hat{\partial}g(Mx^*) \subseteq \partial f(x^*) + \hat{\partial}(g \circ M)(x^*) \subseteq \hat{\partial}(f + g \circ M)(x^*).\]

Consequently, by combining Lemma 4.3 and Fact 2.2(i), we derive that \((x^*, z^*)\) solves \((P)\). \(\Box\)

We see that any critical point produces a solution of \((P)\). The converse implication, however, requires a constraint qualification.

**Lemma 4.7.** Suppose that Assumption 4.1 and one of the following assertions hold:

(i) \(0 \in \text{ri}(\text{dom} g - M(\text{dom} f))\);

(ii) \((\text{ri dom} g) \cap (\text{ri} M(\text{dom} f)) \neq \emptyset\);

(iii) \((\text{int dom} g) \cap M(\text{dom} f) \neq \emptyset \quad \text{or} \quad (\text{dom} g) \cap \text{int}(M(\text{dom} f)) \neq \emptyset\).

10
Then the existence of critical points of $L_0$ is equivalent to the existence of solutions of $(P)$.

Proof. ($\Rightarrow$): Follows from Lemma 4.6.

($\Leftarrow$): We note that either (ii) or (iii) implies (i) (see, e.g., [4, Proposition 6.19]). Set $\tilde{f}$ and $\tilde{g}$ to be the convex functions in Remark 4.4. We observe that $\text{dom } f = \text{dom } \tilde{f}$, $\text{dom } g = \text{dom } \tilde{g}$, and that

$$\nabla \tilde{f} = \nabla f + \beta M^T M, \quad \nabla \tilde{g} = \nabla g - \beta \text{Id}.$$ 

Since the constraint qualification $0 \in \text{ri}(\text{dom } \tilde{g} - M(\text{dom } \tilde{f}))$ is satisfied, by employing subdifferential calculus (see [4, Theorem 16.47]) we arrive at

$$\nabla (f + g \circ M) = \nabla (\tilde{f} + \tilde{g} \circ M)$$
$$= \nabla \tilde{f} + M^T \circ \nabla \tilde{g} \circ M$$
$$= \nabla f + \beta M^T M + M^T \circ \nabla g - \beta M^T M$$
$$= \nabla f + M^T \circ \nabla g \circ M.$$ 

Finally, by invoking Lemma 4.3, if $(x^*, z^*)$ is a solution of $(P)$, then

$$z^* = Mx^* \quad \text{and} \quad 0 \in \nabla (f + g \circ M)(x^*) = \nabla f(x^*) + M^T \circ \nabla g \circ M(x^*).$$

Consequently, there exists $y^* \in \mathbb{R}^m$ such that $(x^*, z^*, y^*)$ is a critical point of $L_0$. \qed

The notion of a critical point and the one of a saddle point coincide in the case where both functions $f$ and $g$ are convex. We now show that in the case where convexity is absent, saddle points are still critical points.

Lemma 4.8 (critical points vs saddle points). Let $f : \mathbb{R}^n \rightarrow ]-\infty, \infty]$ and $g : \mathbb{R}^m \rightarrow ]-\infty, \infty]$ be proper. Then, the saddle points of $L_0$ are also critical points. If, in addition, $f$ and $g$ are convex, then any critical point of $L_0$ is a saddle point.

Proof. Let $x^* \in \text{dom}(f)$, $z^* \in \text{dom}(g)$. Then

$$f(x^*) + g(z^*) + \langle y, Mx^* - z^* \rangle \leq f(x^*) + g(z^*) + \langle y^*, Mx^* - z^* \rangle, \quad \forall y \in \mathbb{R}^m, \quad (8a)$$
$$\iff \langle y - y^*, Mx^* - z^* \rangle \leq 0, \quad \forall y \in \mathbb{R}^m, \quad (8b)$$
$$\iff Mx^* = z^*. \quad (8c)$$

Moreover,

$$f(x^*) + g(z^*) + \langle y^*, Mx^* - z^* \rangle \leq f(x) + g(z) + \langle y^*, Mx - z \rangle, \quad \forall (x, z) \in \mathbb{R}^n \times \mathbb{R}^m, \quad (9)$$

is equivalent to

$$f(x^*) + \langle y^*, Mx^* \rangle \leq f(x) + \langle y^*, Mx \rangle, \quad \forall x \in \mathbb{R}^n,$$

and

$$g(z^*) - \langle y^*, z^* \rangle \leq g(z) - \langle y^*, z \rangle, \quad \forall z \in \mathbb{R}^m.$$
i.e.,
\[-M^T y^* \in \partial f(x^*) \quad \text{and} \quad y^* \in \partial g(z^*) \subseteq \hat{\partial} g(z^*).\]

Hence, if \((x^*, z^*, y^*)\) is a saddle point, then \((x^*, z^*, y^*)\) is a critical point of \(L_0\).

Conversely, if, in addition, \(f\) and \(g\) are convex and if \((x^*, z^*, y^*)\) is a critical point of \(L_0\), then
\[Mx^* = z^*, \quad -M^T y^* \in \partial f(x^*) \quad \text{and} \quad y^* \in \hat{\partial} g(z^*) = \partial g(z^*),\]
which implies (8a) and (9), i.e., \((x^*, z^*, y^*)\) is a saddle point of \(L_0\). \(\square\)

In view of the relations between the critical points of \(L_0\) and the solutions of \((P)\), we impose the existence of a critical point in our convergence analysis.

**Assumption 4.9.** The Lagrangian \(L_0\) has a critical point.

**Remark 4.10.** Assumption 4.9 is standard in the analysis of the ADMM and its variants in the convex framework. In this case Lemma 4.8 implies that it is equivalent to the existence of saddle points, which is assumed in several classical studies such as [9, 18, 19].

Other authors obtain the existence of critical/saddle points from the nonemptiness of the solution set of \((P)\) when combined with one of the constraint qualifications in Lemma 4.7. For instance, the *Slater constraint qualification* in Lemma 4.7(ii) is used in [10, 13] while [8, 30] incorporate the assumption in Lemma 4.7(i).

We now relate the critical points of the Lagrangian to the zeros of \(Q + S\), where \(Q\) and \(S\) are the operators defined by
\[
Q : \mathbb{R}^m \rightrightarrows \mathbb{R}^m : y \mapsto \{-Mx : -M^T y \in \partial f(x)\} = (-M) \circ (\partial f)^{-1} \circ (-M^T)(y), \quad (10a)
\]
\[
S : \mathbb{R}^m \rightrightarrows \mathbb{R}^m : y \mapsto \{z : y \in \hat{\partial} g(z)\} = (\hat{\partial} g)^{-1}(y). \quad (10b)
\]

We will address the convergence of our aADMM by applying the adaptive DR algorithm [15] to \(Q\) and \(S\). This is a natural extension of the classical relation between the ADMM and the DR algorithm in the convex case (see, e.g., [18, 30]) to our generalized settings.

**Proposition 4.11.** The Lagrangian \(L_0\) has a critical point if and only if \(\text{zer}(Q + S) \neq \emptyset\), where \(Q\) and \(S\) are the operators defined in (10). More precisely, \(y^* \in \text{zer}(Q + S)\) if and only if there exist \(x^* \in \mathbb{R}^n\) and \(z^* \in \mathbb{R}^m\) such that \((x^*, z^*, y^*)\) is a critical point of \(L_0\).

**Proof.** We observe that \(y^* \in \text{zer}(Q + S)\) if and only if there exists \(z^* \in \mathbb{R}^m\) such that
\[z^* \in S(y^*) \quad \text{and} \quad -z^* \in Q(y^*). \quad (11)\]

The definition of \(Q\) and \(S\) implies that (11) is equivalent to \(y^* \in \hat{\partial} g(z^*)\) and the existence of \(x^* \in \mathbb{R}^n\) such that \(z^* = Mx^*\) and \(-M^T y^* \in \partial f(x^*),\) that is, \((x^*, z^*, y^*)\) is a critical point of \(L_0\). \(\square\)
4.3 The algorithm

We now formulate our adaptive version of the Alternating Directions Method of Multipliers, aADMM for short. The steps of the aADMM are analogous to the steps of the classical ADMM in (2), however, the aADMM is admissible in the strongly-weakly convex setting and it accommodates different penalty parameters in the two minimization steps. Specifically, we set an initial point \((x^0, z^0, y^0) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) and two parameters \(\gamma, \delta > 0\). Then the aADMM iterates according to the recurrences

\[
x^{k+1} = \arg\min_{x \in \mathbb{R}^n} L_\gamma(x, z^k, y^k),
\]

\[
z^{k+1} = \arg\min_{z \in \mathbb{R}^m} L_\delta(x^{k+1}, z, y^k),
\]

\[
y^{k+1} = y^k + \delta(Mx^{k+1} - z^{k+1}),
\]

equivalently,

\[
x^{k+1} = \arg\min_{x \in \mathbb{R}^n} \left\{ f(x) + \frac{\gamma}{2} \|Mx - z^k + \frac{y^k}{\gamma}\|^2 \right\},
\]

\[
z^{k+1} = \arg\min_{z \in \mathbb{R}^m} \left\{ g(z) + \frac{\delta}{2} \|Mx^{k+1} - z + \frac{y^k}{\delta}\|^2 \right\},
\]

\[
y^{k+1} = y^k + \delta(Mx^{k+1} - z^{k+1}).
\]

Clearly, by letting \(\gamma = \delta\), we obtain the steps of the original ADMM. Similar to the ADMM, the aADMM is only valid if the \(x^k\)-step in (12a) and the \(z^k\)-step in (12b) (equivalently, (13a) and (13b), respectively) are well defined. We will examine this issue in relation to the operators \(Q\) and \(S\) in (10). Our next argument follows the footsteps of [20] (see also [18]). It forms a foundation for convergence analysis of the aADMM by providing a sufficient condition for the existence of the \(z\)-update via the maximal comonotonicity of \(S\).

**Lemma 4.12 (existence of the \(z\)-update).** Let \(g : \mathbb{R}^m \to ]-\infty, \infty[\) be proper, \(\beta\)-convex and lower semicontinuous. Let \(x^{k+1} \in \mathbb{R}^n, y^k \in \mathbb{R}^m\) and \(\delta > \max\{0, -\beta\}\). Then the operator \(S\) defined by (10b) is maximally \(\beta\)-comonotone. Consequently, \(J_{\delta S}\) is single-valued with full domain and \(z^{k+1}\) defined in (12b) is uniquely determined by

\[
z^{k+1} = \frac{1}{\delta}(\text{Id} - J_{\delta S})(y^k + \delta Mx^{k+1}),
\]

and

\[
y^{k+1} = y^k + \delta(Mx^{k+1} - z^{k+1}) = J_{\delta S}(y^k + \delta Mx^{k+1}).
\]

**Proof.** Since \(g\) is \(\beta\)-convex, Fact 3.3 implies that \(\partial g\) is maximally \(\beta\)-monotone. Consequently, it follows from Fact 3.5(i) that \(S = (\partial g)^{-1}\) is maximally \(\beta\)-comonotone.

Now, since \(\delta > -\beta\), Fact 3.4 implies that \(J_{\delta S}\) is single-valued and has full domain. Furthermore, since \(g\) is \(\beta\)-convex and \(\delta > -\beta\), the function inside the argmin in (12b) is convex. By employing Fact 2.2 (iii) and then (v), we see that

\[
z^{k+1}\text{ satisfies (12b) } \iff 0 \in \partial g(z^{k+1}) - y^k - \delta(Mx^{k+1} - z^{k+1})
\]
\[ y^{k+1} \in \hat{\delta} g(z^{k+1}) \]
\[ z^{k+1} \in S(y^{k+1}) \]
\[ y^{k+1} + \delta z^{k+1} \in (\text{Id} + \delta S)(y^{k+1}) \]
\[ y^{k+1} = J_{\delta S}(y^{k+1} + \delta z^{k+1}) = J_{\delta S}(y^{k} + \delta M x^{k+1}) \]

which completes the proof. \[ \Box \]

We now provide a general condition for the existence of the \( x \)-update. We dedicate Section 4.4 to a detailed discussion of cases where this condition is satisfied.

**Lemma 4.13.** Let \( M \in \mathbb{R}^{m \times n} \) be nonzero and let \( f : \mathbb{R}^n \rightarrow ]-\infty, \infty] \) be proper, lower semicontinuous and \( \alpha \)-convex, where \( \alpha \in \mathbb{R}_+ \). Then the operator \( Q \) defined in (10a) is \( \frac{\alpha}{\|M\|^2} \)-comonotone.

**Proof.** Let \((y_1, -M x_1), (y_2, -M x_2) \in gra Q\). Then, \((x_1, -M^T y_1), (x_2, -M^T y_2) \in gra \partial f\). Since \( f \) is \( \alpha \)-convex, Fact 3.3 implies that \( \partial f \) is \( \alpha \)-monotone. Consequently,
\[ \langle x_1 - x_2, -M^T(y_1 - y_2) \rangle \geq \alpha \|x_1 - x_2\|^2 \]
which implies that
\[ (-M(x_1 - x_2), y_1 - y_2) \geq \frac{\alpha}{\|M\|^2} \|M\|^2 \|x_1 - x_2\|^2 \geq \frac{\alpha}{\|M\|^2} \|M(x_1 - x_2)\|^2. \]
Thus, \( Q \) is \( \frac{\alpha}{\|M\|^2} \)-comonotone. \[ \Box \]

**Lemma 4.14 (conditions for the existence of the \( x \)-update).** Let \( f : \mathbb{R}^n \rightarrow ]-\infty, \infty] \) be proper, convex and lower semicontinuous. Let \( M \in \mathbb{R}^{m \times n} \) be nonzero. Let \( y^k, z^k \in \mathbb{R}^m \) and \( \gamma > 0 \). Then the following assertions are equivalent.

(i) \( x^{k+1} \) satisfies (12a);
(ii) \( x^{k+1} \in (\partial f)^{-1}(-M^T v^k) \), where \( v^k = y^k + \gamma(M x^{k+1} - z^k) \);
(iii) \( v^k = J_{\gamma Q}(y^k - \gamma z^k) \), where \( Q \) is defined by (10a).

Consequently, \( x^{k+1} \) in (12a) exists for all \( (y^k, z^k) \) if and only if \( J_{\gamma Q} \) has full domain.

**Proof.** By invoking Fact 2.2 (iii) and (v), we see that
\[ x^{k+1} \] satisfies (12a)
\[ \iff 0 \in \partial f(x^{k+1}) + M^T y^k + \gamma M^T (M x^{k+1} - z^k) \]
\[ \iff -M^T v^k \in \partial f(x^{k+1}) \text{ where } v^k = y^k + \gamma(M x^{k+1} - z^k) \]
\[ \iff x^{k+1} \in (\partial f)^{-1}(-M^T v^k) \text{ where } y^k - \gamma z^k - v^k = -\gamma M x^{k+1} \]
\[ \iff y^k - \gamma z^k - v^k \in -\gamma M \circ (\partial f)^{-1} \circ (-M^T)(v^k) \]
\[ \iff y^k - \gamma z^k \in (\text{Id} + \gamma Q)(v^k) \]
\[ \iff v^k = J_{\gamma Q}(y^k - \gamma z^k). \]
In (14) we employed the single-valuedness of \( J_{\gamma Q} \) which follows from Lemma 4.13 when combined with Fact 3.4(i). \[ \Box \]
4.4 Constraint qualifications for the $x$-update

While the $z$-update is already well-defined under a generalized convexity assumption (by Lemma 4.12), the $x$-update depends on the resolvent of $Q$ having full domain (by Lemma 4.14). We now discuss constraint qualifications for the maximal comonotonicity of $Q$, which, in turn, guarantees full domain of its resolvent. To this end we assume that

**Assumption 4.15.** The following constraint qualification holds:

$$0 \in \text{ri}(\text{dom } f^* - \text{ran } M^T). \tag{15}$$

Assumption 4.15 is satisfied in several cases which we detail in the following lemma. Some of the historical context and references to such cases in the classical ADMM literature are provided in Remark 4.18.

**Lemma 4.16 (sufficient conditions for Assumption 4.15).** Let $f : \mathbb{R}^n \to ]-\infty, +\infty]$ be proper, convex and lower semicontinuous. Let $M \in \mathbb{R}^{m \times n}$. Then each of the following conditions implies (15):

(i) $\text{ri}(\text{dom } f^*) \cap \text{ran } M^T \neq \emptyset$.

(ii) $\text{ri}(\text{ran } \partial f) \cap \text{ran } M^T \neq \emptyset$.

(iii) $(\text{rec } f)(x) > 0$ for all $x \in \ker M \setminus \{x \in \mathbb{R}^n : -(\text{rec } f)(-x) = (\text{rec } f)(x) = 0\}$.

(iv) $f$ is coercive (in particular, supercoercive).

(v) $f$ is strongly convex.

(vi) $M^T M$ is invertible.

**Proof.** (i): By [32, Corollary 6.6.2],

$$\text{ri}(\text{dom } f^* - \text{ran } M^T) = \text{ri}(\text{dom } f^*) - \text{ran } M^T.$$ 

Consequently, (i) follows from [4, Corollary 6.15].

(ii): By invoking (i), it suffices to show that

$$\text{ri}(\text{dom } f^*) = \text{ri}(\text{ran } \partial f). \tag{16}$$

Indeed, by [4, Proposition 16.4(i) and Corollary 16.18(i)],

$$\text{ri dom } f^* \subseteq \text{dom } \partial f^* \subseteq \text{dom } f^*.$$ 

Now, by employing [32, Theorem 6.3],

$$\text{cl}(\text{dom } f^*) = \text{cl}(\text{dom } \partial f^*) \text{ and } \text{ri}(\text{dom } f^*) = \text{ri}(\text{dom } \partial f^*).$$

Finally, since $\text{dom } \partial f^* = \text{ran } \partial f$, we arrive at (16).
We consider the function \( F = f + h \), where \( h = \eta \| M(\cdot) - a \|^2 \) for some \( a \in \mathbb{R}^m \) and \( \eta > 0 \). By [4, Proposition 9.30(vi)],

\[
\text{rec } F = \text{rec } f + \text{rec } h.
\]

Moreover, since \( \| \cdot \|^2 \) is supercoercive, [4, Proposition 9.30(vii) and Example 9.32] imply that

\[
(\text{rec } h)(x) := \begin{cases} 
0, & \text{if } Mx = 0, \\
+\infty, & \text{otherwise}.
\end{cases}
\]

Hence, (iii) implies that \( (\text{rec } F)(x) > 0 \) for all vectors \( x \in \mathbb{R}^n \) except those satisfying \( -\text{rec } F(-x) = \text{rec } F(x) = 0 \). By [32, Corollary 13.3.4(b)], this is equivalent to

\[
0 \in \text{ri}(\text{dom } F^*).
\]

On the other hand, since \( \text{dom } h^* = \text{ran } M^T \), by employing [4, Proposition 12.6(ii)] we see that

\[
\text{dom } f^* - \text{ran } M^T = \text{dom } f^* + \text{dom } h^* = \text{dom}(f^* \square h^*).
\]

Now, since \( h \) has full domain, \( 0 \in \text{int}(\text{dom } f - \text{dom } h) \). Consequently, by [33, Theorem 11.23(a)] we arrive at

\[
f^* \square h^* = (f + h)^* \quad \text{which, in turn, implies that}
\]

\[
\text{dom } f^* - \text{ran } M^T = \text{dom}(f^* \square h^*) = \text{dom}(f + h)^* = \text{dom } F^*.
\]

By combining (17) and (18) we obtain (15).

(iv): If \( f \) is coercive, then [4, Proposition 14.16] implies that \( 0 \in \text{int}(\text{dom } f^*) \subseteq \text{ri}(\text{dom } f^*) \).

Since, clearly, \( 0 \in \text{ran } M^T \), we employ (i) and conclude (15).

(v): Follows from (iv) since every strongly convex function is coercive.

(vi): If \( M^T M \) is invertible, then \( \text{ran } M^T = \mathbb{R}^n \). Since \( \text{dom } f^* \neq \emptyset \), (15) follows trivially.

We now prove the existence of the \( x \)-update via maximal comonotonicity of \( Q \) which is guaranteed by Assumptions 4.1 and 4.15.

**Lemma 4.17 (existence of the \( x \)-update under constraint qualifications).** Let \( M \in \mathbb{R}^{m \times n} \) be nonzero and let \( f : \mathbb{R}^n \to ]-\infty, \infty[ \) be proper, lower semicontinuous, and \( \alpha \)-convex for some \( \alpha \in \mathbb{R}_+ \). Let Assumption 4.15 hold. Then the operator \( Q \) defined in (10a) is maximally \( \frac{\alpha}{\|M\|^2} \)-comonotone. Consequently, the \( x \)-update in (12a) is well-defined and

\[
y^{k+1} + \gamma(Mx^k - z^k) = J_{\gamma Q}(y^k - \gamma z^k).
\]

**Proof.** Since \( f \) is convex, proper and lsc, so is \( f^* \) (see, e.g., [4, Proposition 13.13]). Consequently, since Assumption 4.15 holds, the constraint qualifications in the chain rule [32, Theorem 23.9] (see also [4, Corollary 16.53]) are met for the convex function \( f^* \) and the linear operator \( -M^T \) and we obtain

\[
\partial(f^* \circ (-M^T)) = (-M) \circ (\partial f^*) \circ (-M^T) = (-M) \circ (\partial f)^{-1} \circ (-M^T) = Q.
\]

(19)
We see that $Q$ is the subdifferential of the proper, convex and lower semicontinuous function $f^* \circ (-M^T)$ and, as such, $Q$ is maximally monotone by Fact 3.3. It now follows that $Q$ is maximally $\frac{\alpha}{\|M\|^2}$-comonotone by Lemma 4.13 and Fact 3.5(ii).

Finally, Fact 3.4 implies that $J_{\gamma Q}$ is single-valued with full domain. The existence of the $x$-update now follows from Lemma 4.14.

\[ \text{Remark 4.18.} \] Assumption 4.15 and several of the constraint qualification in Lemma 4.16 have been widely used for the analysis of the classical ADMM in the literature. In this relation, we list some classical and recent references:

(i) In [20] the convergence of the ADMM for the variational inequality problem

\[
\text{find } x, w \in \mathbb{R}^n \text{ such that } w \in A(x) \quad \text{and} \quad \langle w, y - x \rangle + g(My) - g(Mx) \geq 0, \quad \forall y \in \mathbb{R}^n; \]

was established. One of the assumptions is that either $A$ is strongly monotone or $M^TM$ is an isomorphism (see [20, Theorem 5.1]). When applied to problem (P), these assumptions become

$f$ is strongly convex or $M^TM$ is invertible,

which implies Assumption 4.15 by Lemma 4.16 (iv) and (vi).

(ii) [9] is one of the most widely cited studies of the ADMM. Therein, no conditions are imposed (apart from the existence of saddle points; see Remark 4.10) in order to derive convergence of the ADMM. However, it was pointed out in [10] that this may fail since in this case the steps of the ADMM may not be well-defined, i.e., the argmins may not exist. In particular, for the existence of $x^{k+1}$, the authors of [10] require the condition in Lemma 4.16(iii) (see [10, Assumption 1]).

(iii) In [35], the condition in Lemma 4.16(i) was imposed to guarantee the existence of $x^{k+1}$.

(iv) In [17], the condition in Lemma 4.16(ii) was utilized in order to obtain the chain rule in (19). It was referred to as dual normality (see [17, Definition 3.22 and Proposition 3.30]). The argument therein also follows directly from [32, Theorem 23.9]. The chain rule leads to the maximal monotonicity of $Q$, which, in turn, guarantees the existence of $x^{k+1}$.

(v) The invertibility of $M^TM$ in Lemma 4.16(vi) is, arguably, the most common assumption for the convergence of ADMM in the literature. Indeed, it is assumed in [1, 8, 13, 19, 30], to name a few.

Although $M^TM$ being invertible or $f$ being strongly convex are two of the more restrictive conditions in Lemma 4.16, as we show next, they do provide an additional strength: uniqueness of the $x$-update which, in turn, implies convergence of the sequence $(x^k)_{k=0}^\infty$. Assumption 4.15 alone only guarantees the convergence of the sequence $(Mx^k)_{k=0}^\infty$ (see Theorem 5.2).

\[ \text{Lemma 4.19 (criteria for uniqueness of the } x\text{-update).} \] Let $M \in \mathbb{R}^{m \times n}$ be nonzero and let $f : \mathbb{R}^n \to ]-\infty, \infty]$ be proper, lower semicontinuous and $\alpha$-convex, where $\alpha \in \mathbb{R}_+$. Set

\[
v^k := J_{\gamma Q}(y^k - \gamma z^k) \text{ where } Q \text{ is the operator defined in (10a)}.\]
The following hold.

(i) If \( \alpha > 0 \) (i.e. \( f \) is strongly convex), then \( (\partial f)^{-1} \) is Lipschitz continuous and the \( x \)-update in (12a) is uniquely defined by

\[
x^{k+1} = (\partial f)^{-1}(-M^T v^k).
\]

(ii) If \( M^T M \) is invertible, then the \( x \)-update in (12a) is uniquely defined by

\[
x^{k+1} = (M^T M)^{-1} M^T \left( \frac{1}{\gamma} (v^k - y^k) + z^k \right).
\]

Proof. By employing Lemma 4.16(v) and Lemma 4.16(vi), respectively, we see that the conditions in (i) and (ii) imply Assumption 4.15. Consequently, Lemma 4.17 implies that the \( x \)-update in (12a) is well-defined and

\[
v^k := y^k + \gamma (M x^{k+1} - z^k) = J_{\gamma Q}(y^k - \gamma z^k).
\]

Now, if \( f \) is \( \alpha \)-strongly convex \((\alpha > 0)\), then by combining Fact 3.3 with Fact 3.5(i) we see that \( (\partial f)^{-1} \) is maximally \( \alpha \)-comonotone. Consequently, \( (\partial f)^{-1} \) is Lipschitz continuous, in particular, single-valued. It follows that the inclusion in Lemma 4.14(ii) is an equality, i.e.,

\[
x^{k+1} = (\partial f)^{-1}(-M^T v^k).
\]

If \( M^T M \) is invertible, since \( v^k = y^k + \gamma (M x^{k+1} - z^k) \), we conclude that

\[
x^{k+1} = (M^T M)^{-1} (M^T M) x^{k+1} = (M^T M)^{-1} M^T \left( \frac{1}{\gamma} (v^k - y^k) + z^k \right)
\]

which completes the proof.

Remark 4.20. We note that Lemma 4.19 is directly implied by (13a). Indeed, if \( f \) is strongly convex or \( M \) has full column rank (i.e. \( M^T M \) is invertible), then the function inside the argmin in (13a) is strongly convex, which, in turn, implies existence and uniqueness of minimizers.

5 Convergence of the aADMM

In order to obtain convergence of the aADMM, we adapt \( \gamma \) and \( \delta \) to the convexity parameters of the two functions \( f \) and \( g \). We will employ the following lemma in order to guarantee existence of such parameters.

Lemma 5.1 (existence of parameters). Let \( \alpha, \beta \in \mathbb{R} \) such that \( \alpha + \beta > 0 \). Then for every \( \gamma, \delta \in \mathbb{R}_{++} \) the following assertions are equivalent.

(i) \( 2\delta (\alpha + \beta) + (\gamma + \delta)^2 < 4(\gamma + \alpha)(\delta + \beta) \).

(ii) \( \delta + 2\beta > 0 \) and \( \gamma \in \left[ \delta + 2\beta - \sqrt{2(\alpha + \beta)(\delta + 2\beta)}, \delta + 2\beta + \sqrt{2(\alpha + \beta)(\delta + 2\beta)} \right] \).
Proof. A straightforward computation implies that
\[2\delta(\alpha + \beta) + (\gamma + \delta)^2 < 4(\gamma + \alpha)(\delta + \beta)\]
\[\iff \gamma^2 - 2(\delta + 2\beta)\gamma + (\delta + 2\beta)(\delta - 2\alpha) < 0\]
\[\iff \left\{ \begin{array}{l}
\delta + 2\beta > 0, \\
\delta + 2\beta - \sqrt{2(\alpha + \beta)(\delta + 2\beta)} < \gamma < \delta + 2\beta + \sqrt{2(\alpha + \beta)(\delta + 2\beta)};
\end{array} \right.\]
which completes the proof.

Theorem 5.2 (convergence of the aADMM). Suppose that Assumptions 4.1, 4.9 and 4.15 hold. Let \(\delta > \max\{0,-2\beta\}\) and set
\[
\gamma = \delta + 2\beta, \quad \text{if } \alpha + \beta \|M\|^2 = 0,
\]
\[
\gamma \in \max\{0,\delta + 2\beta - \Delta_\delta\}, \delta + 2\beta + \Delta_\delta[\,, \quad \text{if } \alpha + \beta \|M\|^2 > 0;
\]
where
\[\Delta_\delta := \frac{1}{\|M\|} \sqrt{2(\alpha + \beta\|M\|^2)(\delta + 2\beta)}.\]
Set \((x^0, z^0, y^0) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) and let \((x^k, z^k, y^k)_{k=0}^\infty\) be generated by the aADMM (12). Then
\[Mx^k \to Mx^*, \quad z^k \to z^* \quad \text{and} \quad y^k \to y^*\]
where \((x^*, z^*, y^*)\) is a critical point of \(L_0(x, z, y)\). Consequently, \((x^*, z^*)\) is a solution of \((P)\).

Proof. Let \(Q\) and \(S\) be defined by (10). Our aim is to establish that the sequence generated by the aADMM (12) corresponds to the sequence generated by the aDR (6) when applied to \(Q\) and \(S\). Note that \(\text{zer}(Q + S) \neq \emptyset\) due to Assumption 4.9 and Proposition 4.11.

On the one hand, for any \(\beta\), it holds that \(\max\{0,-2\beta\} \geq \max\{0,-\beta\}\). So \(\delta > \max\{0,-\beta\}\). Consequently, Lemma 4.12 implies that \(S\) is maximally \(\beta\)-comonotone and that the \(z\)-update in (12b) is uniquely defined by
\[y^{k+1} = J_{\delta S}(y^{k+1} + \delta z^{k+1}).\]
On the other hand, Lemma 4.17 implies that \(Q\) is maximally \(\frac{\alpha}{\|M\|^2}\)-comonotone, that the \(x\)-update in (12a) is well defined and
\[v^k := y^k + \gamma(Mx^{k+1} - z^k) = J_{\gamma Q}(y^k - \gamma z^k).\]
Set \(w^k := y^k + \delta z^k\) for each \(k = 0, 1, 2, \ldots\). Set further
\[\lambda := 1 + \frac{\delta}{\gamma} \quad \text{and} \quad \mu := 1 + \frac{\gamma}{\delta}.\]
Then, clearly, \( \lambda, \mu \) satisfy (4). We employ \( J_{\delta S} \) and \( J_{\gamma Q} \) in order to compute \( J_{\delta S}^\lambda(J_{\delta S}^\mu(w^k)) \) via the following steps:

\[
\begin{align*}
J_{\delta S}(w^k) &= J_{\delta S}(y^k + \delta z^k) = y^k, \\
J_{\delta S}^\mu(w^k) &= (1 - \mu)w^k + \mu J_{\delta S}(w^k) \\
&= (1 - \mu)(y^k + \delta z^k) + \mu y^k \\
&= y^k + (1 - \mu)\delta z^k \\
&= y^k - \gamma z^k,
\end{align*}
\]

and so,

\[
\begin{align*}
J_{\gamma Q}(J_{\delta S}^\mu(w^k)) &= J_{\gamma Q}(y^k - \gamma z^k) = v^k,
\end{align*}
\]

We also observe that \( w^{k+1} = y^{k+1} + \delta z^{k+1} = y^k + \delta M x^{k+1} = y^k + (\lambda - 1)\gamma M x^{k+1} = w^k + (\lambda - 1)(v^k - y^k) + \delta z^k \).

Consequently, by setting \( \kappa := \frac{\lambda - 1}{\lambda} = \frac{\delta}{\gamma + \delta} \in [0, 1] \) and by recalling (6) we arrive at

\[
T_{\text{aDR}}(w^k) := (1 - \kappa)w^k + \kappa J_{\gamma Q}^\lambda(J_{\delta S}^\mu(w^k)) = w^k + (\lambda - 1)(v^k - y^k) = w^{k+1}.
\]

Summing up, the sequence \( (w^k)_{k=0}^{\infty} \) is generated by the aDR algorithm applied to \( S \) and \( Q \).

We now apply Fact 3.7 to the two operators \( Q \) and \( S \). To this end, it suffices to check that the conditions in Fact 3.7 for the parameters, i.e., conditions (3) and (5) for \( \frac{\alpha}{\|M\|^2}, \beta, \gamma, \delta, \) and \( \kappa \), are met. By Assumption 4.1,

\[
\frac{\alpha}{\|M\|^2} + \beta \geq 0.
\]

If \( \frac{\alpha}{\|M\|^2} + \beta = 0 \), then (20a) implies \( \delta = \gamma - 2\beta = \gamma + 2\frac{\alpha}{\|M\|^2} \), that is, (3a) is satisfied.

If \( \frac{\alpha}{\|M\|^2} + \beta > 0 \), then, by Lemma 5.1, we see that (20b) implies that

\[
2\delta \left( \frac{\alpha}{\|M\|^2} + \beta \right) + (\gamma + \delta)^2 < 4 \left( \gamma + \frac{\alpha}{\|M\|^2} \right) (\delta + \beta) \tag{21a}
\]

\[
\Longleftrightarrow \frac{\delta}{\gamma + \delta} < \frac{4 \left( \gamma + \frac{\alpha}{\|M\|^2} \right) (\delta + \beta) - (\gamma + \delta)^2}{2(\gamma + \delta) \left( \frac{\alpha}{\|M\|^2} + \beta \right)} =: \overline{\kappa}. \tag{21b}
\]

On the one hand, (21a) implies

\[
(\gamma + \delta)^2 < 4 \left( \gamma + \frac{\alpha}{\|M\|^2} \right) (\delta + \beta),
\]

On the other hand, (21b) implies

\[
\frac{\delta}{\gamma + \delta} < \frac{4 \left( \gamma + \frac{\alpha}{\|M\|^2} \right) (\delta + \beta) - (\gamma + \delta)^2}{2(\gamma + \delta) \left( \frac{\alpha}{\|M\|^2} + \beta \right)} =: \overline{\kappa}.
\]
which leads to (3b). On the other hand, (21b) implies that $0 < \kappa < \kappa$, i.e., (5) is satisfied.

Consequently, we meet all of the conditions in order to apply Fact 3.7: Fact 3.7(i) implies that $w^k \to w^* \in \text{Fix} T_{\text{ADR}}$ while Fact 3.7(ii) implies that
\[
y^k = J_{\delta S}(w^k) \to J_{\delta S}(w^*) =: y^* \in \text{zer}(Q + S).
\]
By the convergence of $w^k$ and $y^k$ we see that
\[
z^k = \frac{1}{\delta}(w^k - y^k) \to \frac{1}{\delta}(w^* - y^*) =: z^*.
\]
Finally, Fact 3.7(iii) implies that $y^k - v^k \to 0$, thus, $v^k \to y^*$ and
\[
Mx^k \to z^*.
\]
We prove that there exists $x^* \in \mathbb{R}^n$ such that $Mx^* = z^*$ and that $(x^*, z^*, y^*)$ is a critical point. Indeed, we note that
\[
(y^k, z^k)_{k=0}^\infty \subseteq \text{gra} S \quad \text{and} \quad (v^k, -Mx^{k+1})_{k=0}^\infty \subseteq \text{gra} Q.
\]
By taking limits in (22) and by recalling Lemma 3.6, we conclude that $(y^*, z^*) \in \text{gra} S$ and $(y^*, -z^*) \in \text{gra} Q$, equivalently,
\[
y^* \in \partial g(z^*) \quad \text{and} \quad -M^Ty^* \in \partial f(x^*),
\]
for some $x^*$ such that $z^* = Mx^*$. Finally, since we now have a critical point $(x^*, z^*, y^*)$, we invoke Lemma 4.6 which concludes the proof.

Remark 5.3 (on the strongly-weakly convex assumption). In the strongly-weakly convex settings, certain assumptions are usually imposed on the parameters $(\alpha, \beta)$. In our adaptive approach, Assumption 4.1 requires
\[
\alpha + \beta \|M\|^2 \geq 0.
\]
This is an improvement of [31, Assumption 3.1(i)], which can be reformulated in the form
\[
\alpha + \beta \|M\|^2 > 0.
\]
Consequently, our analysis is applicable in the setting of the classical ADMM for convex functions (i.e., $\alpha = \beta = 0$) while [31] is not. This observation aligns with the analysis of the adaptive DR algorithm in [3, 15] (see [15, Remark 5.5]).

Remark 5.4 (parameters in the classical ADMM). We consider the classical ADMM in the case of strong convexity $\alpha + \beta \|M\|^2 > 0$. We then set $\gamma = \delta \in \mathbb{R}_{++}$ for $\delta$ such that $\delta + 2\beta > 0$ and
\[
\delta + 2\beta - \sqrt{2 \left( \frac{\alpha}{\|M\|^2} + \beta \right)} (\delta + 2\beta) < \delta < \delta + 2\beta + \sqrt{2 \left( \frac{\alpha}{\|M\|^2} + \beta \right)} (\delta + 2\beta).
\]
which is equivalent to
\[
\delta > \max \left\{ -2\beta, \frac{-2\alpha\beta}{\alpha + \beta \|M\|^2} \right\} = \frac{-2\alpha\beta}{\alpha + \beta \|M\|^2}, \quad \text{if } \beta \leq 0.
\]

This range of parameters improves the results in [31] which require (see [31, Assumption 3.1(ii)])
\[
\delta > -2\beta + \frac{8\beta^2 \|MM^T\|}{\alpha + \beta \|M\|^2} = \frac{-2\alpha\beta}{\alpha + \beta \|M\|^2} + \frac{6\beta^2 \|M\|^2}{\alpha + \beta \|M\|^2}.
\]

In Theorem 5.2 we see that the sequence \((Mx^k)_{k=0}^\infty\) converges, however there is no indication as to whether \((x^k)_{k=0}^\infty\) converges or not. Similarly to the classical case (see, for instance, [1, Proposition 2.2] and [36, Proposition 2]), this can be remedied if we assume that \(M^TM\) is invertible or \(f\) is strongly convex \((\alpha > 0)\).

**Theorem 5.5 (convergence of the aADMM under stronger assumptions).** Suppose that Assumption 4.1, Assumption 4.9 and one of the following conditions hold:

(i) \(f\) is strongly convex \((i.e., \alpha > 0)\),

(ii) \(M^TM\) is invertible.

Let \(\delta > \max\{0, -2\beta\}\) and let \(\gamma > 0\) satisfy (20). Set \((x^0, z^0, y^0) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) and let \((x^k, z^k, y^k)_{k=0}^\infty\) be generated by the aADMM (12). Then
\[
x^k \rightarrow x^*, \quad z^k \rightarrow z^* \quad \text{and} \quad y^k \rightarrow y^*
\]
where \((x^*, z^*, y^*)\) is a critical point of \(L_0(x, z, y)\). Consequently, \((x^*, z^*)\) is a solution of \((P)\).

**Proof.** By employing Lemma 4.16(v) and Lemma 4.16(vi), respectively, we see that the conditions in (i) and (ii) imply Assumption 4.15. Consequently, we employ Theorem 5.2 in order to obtain a critical point \((x^*, z^*, y^*)\) of \(L_0(x, z, y)\) where
\[
Mx^k \rightarrow Mx^*, \quad z^k \rightarrow z^* \quad \text{and} \quad y^k \rightarrow y^*.
\]
Set \(v^k := y^k + \gamma(Mx^{k+1} - z^k), \quad k = 0, 1, \ldots\) Then \(v^k \rightarrow y^*\). If \(f\) is strongly convex, then, by employing Lemma 4.19(i), we conclude that \((\partial f)^{-1}\) is Lipschitz continuous and
\[
x^{k+1} = (\partial f)^{-1}(-M^Tv^k) \rightarrow (\partial f)^{-1}(-M^Ty^*) = x^*.
\]

Suppose now that \(M^TM\) is invertible. Then, by employing Lemma 4.19(ii), we conclude that
\[
x^{k+1} = (M^TM)^{-1}M^T \left( \frac{1}{\gamma}(v^k - y^k) + z^k \right) \rightarrow (M^TM)^{-1}M^Tz^* = x^*
\]
which completes the proof. \[\square\]
5.1 Summary: Existence and Convergence

For the sake of convenience and accessibility, we recollect and unify all of the conditions from our discussion regarding the existence of a solution of \((P)\) and the convergence of the aADMM and the ADMM.

**Corollary 5.6 (existence and convergence of aADMM).** Let \(M \in \mathbb{R}^{m \times n}\) be a nonzero matrix, let \(f : \mathbb{R}^n \rightarrow ]-\infty, +\infty]\) be proper, lower semicontinuous and \(\alpha\)-convex, and let \(g : \mathbb{R}^m \rightarrow ]-\infty, +\infty]\) be proper, lower semicontinuous and \(\beta\)-convex where \(\alpha, \beta \in \mathbb{R}\) are parameters such that

\[
\alpha \geq 0 \quad \text{and} \quad \alpha + \beta \|M\|^2 \geq 0.
\]

Suppose that one of the following conditions holds:

(A.1) the Lagrangian \(L_0\) has a critical point,

(A.2) the Lagrangian \(L_0\) has a saddle point,

(A.3) problem \((P)\) has an optimal solution and \(0 \in \text{ri}(\text{dom} \, g - M(\text{dom} \, f))\);

and that one of the following conditions holds:

(B.1) \(0 \in \text{ri}(\text{dom} \, f^* - \text{ran} \, M^T)\),

(B.2) \(\text{ri}(\text{ran} \, \partial f) \cap \text{ran} \, M^T \neq \emptyset\),

(B.3) \((\text{rec} \, f)(x) > 0 \quad \text{for all} \quad x \in \ker M \setminus \{x \in \mathbb{R}^n : -(\text{rec} \, f)(-x) = (\text{rec} \, f)(x) = 0\}\),

(B.4) \(f\) is coercive (in particular, supercoercive),

(B.5) \(\alpha > 0\) (i.e., \(f\) is strongly convex),

(B.6) \(M^T \, M\) is invertible.

Let \(\delta > \max\{0, -2\beta\}\) and set

\[
\gamma = \delta + 2\beta, \quad \text{if} \quad \alpha + \beta \|M\|^2 = 0,
\]

\[
\gamma \in \max\{0, \delta + 2\beta - \Delta_\delta\}, \delta + 2\beta + \Delta_\delta\], \quad \text{if} \quad \alpha + \beta \|M\|^2 > 0;
\]

where

\[
\Delta_\delta := \frac{1}{\|M\|} \sqrt{2(\alpha + \beta \|M\|^2) (\delta + 2\beta)}.
\]

Set \((x^0, z^0, y^0) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) and let \((x^k, z^k, y^k)_{k=0}^{\infty}\) be generated by the aADMM (12). Then

\[
M x^k \to M x^*, \quad z^k \to z^* \quad \text{and} \quad y^k \to y^*
\]

where \((x^*, z^*, y^*)\) is a critical point of \(L_0(x, z, y)\). Consequently, \((x^*, z^*)\) is a solution of \((P)\). If, in particular, (B.5) or (B.6) holds, then \(x^k \to x^*\).
Proof. Clearly, Assumption 4.1 holds. By Lemma 4.7 and Lemma 4.8, each one of the conditions (A.1)–(A.3) implies Assumption 4.9. Finally, by Lemma 4.16, each one of the conditions (B.1)–(B.6) implies Assumption 4.15. We conclude the proof by invoking Theorem 5.2 and Theorem 5.5.

As we point out in Remark 5.3, our assumptions on \((P)\) extend the framework of the classical ADMM for two convex functions.

**Corollary 5.7 (existence and convergence of ADMM).** Let \(M \in \mathbb{R}^{m \times n}\) be a nonzero matrix and let \(f : \mathbb{R}^n \to ]-\infty, +\infty]\) and \(g : \mathbb{R}^m \to ]-\infty, +\infty]\) be proper, lower semicontinuous and convex. Suppose that one of the following conditions holds:

(A.1) the Lagrangian \(L_0\) has a saddle point (equivalently, a critical point),

(A.2) problem \((P)\) has an optimal solution and \(0 \in \text{ri}(\text{dom} g - M(\text{dom} f))\);

and that one of the following conditions holds:

(B.1) \(0 \in \text{ri}(\text{dom} f^* - \text{ran} MT)\),

(B.2) \(\text{ri}(\text{ran} \partial f) \cap \text{ran} MT \neq \emptyset\),

(B.3) \((\text{rec} f)(x) > 0 \text{ for all } x \in \ker M \setminus \{x \in \mathbb{R}^n : -(\text{rec} f)(-x) = (\text{rec} f)(x) = 0\}\),

(B.4) \(f\) is coercive (in particular, supercoercive),

(B.5) \(f\) is strongly convex,

(B.6) \(MT\) is invertible.

Let \(\gamma > 0\). Set \((x^0, z^0, y^0) \in \mathbb{R}^n \times \mathbb{R}^m \times \mathbb{R}^m\) and let \((x^k, z^k, y^k)_{k=0}^\infty\) be generated by the ADMM (2). Then

\[
Mx^k \to Mx^*, \quad z^k \to z^* \quad \text{and} \quad y^k \to y^*
\]

where \((x^*, z^*, y^*)\) is a critical point of \(L_0(x, z, y)\). Consequently, \((x^*, z^*)\) is a solution of \((P)\). If, in particular, (B.5) or (B.6) holds, then \(x^k \to x^*\).

**Proof.** The proof follows from Corollary 5.7 when we set \(\alpha = \beta = 0\).

### 5.2 Optimality conditions and stopping criteria

By following [9, § 3.3], we discuss the primal-dual residual stopping criteria for the aADMM which we will employ in Section 6 for our numerical experiments.

By Definition 4.5, \((x^*, z^*, y^*)\) is a critical point if

\[
\begin{align*}
0 & \in \partial f(x^*) + MTy^*, \\
0 & \in \hat{\partial} g(z^*) - y^*, \\
Mx^* & - z^* = 0.
\end{align*}
\]

(23a)  
(23b)  
(23c)  

24
Clearly, the sequence \( r^k := Mx^k - z^k \) can be viewed as residual for (23c). By optimality at each step in (12) we obtain
\[
0 \in \partial f(x^{k+1}) + M^Ty^k + \gamma M^T(Mx^{k+1} - z^k),
0 \in \tilde{\partial}g(z^{k+1}) - y^k - \delta(Mx^{k+1} - z^{k+1}).
\]

We note that \( y^{k+1} = y^k + \delta(Mx^{k+1} - z^{k+1}) \). Consequently,
\[
0 \in \partial f(x^{k+1}) + M^Ty^{k+1} - \delta M^T(Mx^{k+1} - z^{k+1}) + \gamma M^T(Mx^{k+1} - z^k),
0 \in \tilde{\partial}g(z^{k+1}) - y^{k+1}.
\]

We see that (23b) holds at each step whereas for (23a) we will monitor the dual residual
\[
s^{k+1} := -\delta M^T(Mx^{k+1} - z^{k+1}) + \gamma M^T(Mx^{k+1} - z^k)
= M^T(\gamma z^k - \delta z^{k+1} - (\gamma - \delta)Mx^{k+1}).
\]

We will therefore employ the primal-dual residual stopping criteria
\[
\|r^k\| := \|Mx^k - z^k\| \leq \epsilon_{primal}, \quad (26a)
\|s^k\| := \|M^T(\gamma z^{k+1} - \delta z^k - (\gamma - \delta)x^k)\| \leq \epsilon_{dual}, \quad (26b)
\]
for some fixed \( \epsilon_{primal} > 0 \) and \( \epsilon_{dual} > 0 \). We note that the case where \( \delta = \gamma \) in (26) coincides with the primal-dual stopping criteria employed for the classical ADMM (see [9, §3.3]). Finally, \( \epsilon_{primal} \) and \( \epsilon_{dual} \) may be chosen using absolute and relative tolerances, for example,
\[
\epsilon_{primal} = \sqrt{m} \epsilon_{abs} + \epsilon_{rel} \max\{\|Mx^k\|, \|z^k\|\},
\epsilon_{dual} = \sqrt{n} \epsilon_{abs} + \epsilon_{rel} \|M^Tz^k\|,
\]
where \( m \) and \( n \) are the dimensions of the matrix \( M \).

**Remark 5.8 (Stopping criteria from the aDR perspective).** As a counterpart, we examine the stopping criteria from the perspective of the aDR algorithm. By employing the notations in the proof of Theorem 5.2, we consider
\[
w^k := y^k + \delta z^k \implies y^k = J_{\delta S}(w^k).
\]
Since \( w^k \to w^* \in \text{Fix}T_{aDR} \), it is reasonable to employ the Cauchy-type stopping criteria
\[
\|w^{k+1} - w^k\| \leq \epsilon_{aDR}. \quad (27)
\]
We observe that
\[
r^k = \delta^{-1}(y^k - y^{k-1}),
s^k = M^T((\delta - \gamma)Mx^k - \delta z^k + \gamma z^k) + M^T\gamma(z^{k-1} - z^k)
= M^T(\delta - \gamma)y^k + M^T\gamma(z^{k-1} - z^k).
\]
Consequently, (26) is equivalent to \( \|y^{k+1} - y^k\| \) and \( \|z^{k+1} - z^k\| \) being small. By the triangle inequality,
\[
\|w^{k+1} - w^k\| \leq \|y^{k+1} - y^k\| + \delta \|z^{k+1} - z^k\|. \tag{28}
\]
On the other hand, since \( z^k \in S(y^k) \) and \( S \) is maximally \( \beta \)-comonotone, we obtain
\[
\begin{align*}
\|w^{k+1} - w^k\|^2 &= \|y^{k+1} - y^k\|^2 + \delta^2 \|z^{k+1} - z^k\|^2 + 2\delta (y^{k+1} - y^k, z^{k+1} - z^k) \\
&\geq \|y^{k+1} - y^k\|^2 + \delta (\delta + 2\beta) \|z^{k+1} - z^k\|^2. \tag{29}
\end{align*}
\]
In view of (28) and (29), we see that the Cauchy stopping criteria (27) with appropriately chosen \( \epsilon_{aDR} \) is equivalent to (26), which justifies the use of primal-dual residual stopping criteria.

6 Numerical experiments

We now examine the applicability and efficiency of our aADMM with numerical experiments. To this end we focus on a total variation signal denoising problem for which the classical ADMM has been widely used (see, e.g., [11, 13, 14, 37] and the references therein). All of our codes are in Python 3.7.

Suppose that a discretized observed signal \( \hat{\phi} \in \mathbb{R}^n \) is the result of
\[
\hat{\phi} = \phi + \xi,
\]
where \( \phi \in \mathbb{R}^n \) is the original signal and \( \xi \in \mathbb{R}^n \) is a Gaussian noise with 0 mean and variance \( \sigma^2 \). The objective of the denoising is to obtain an accurate approximation of \( \phi \) from \( \hat{\phi} \). A common approach consists of solving the total variation regularization problem [34] (see, e.g., [9, §6.4.1])
\[
\min_{x \in \mathbb{R}^n} \frac{1}{2} \|x - \hat{\phi}\|^2 + \omega P(Dx), \tag{30}
\]
where \( \omega > 0 \) is the regularization parameter, \( P : \mathbb{R}^{n-1} \to \mathbb{R}_+ \) is a penalty function in order to induce sparsity and \( D \in \mathbb{R}^{n \times (n-1)} \) is the total variation matrix defined component-wise by
\[
D_{ij} := \begin{cases} 
1, & \text{if } j = i; \\
-1, & \text{if } j = i + 1; \\
0, & \text{otherwise.}
\end{cases}
\]
We observe that problem (30) is of the form \( (P) \) when we let
\[
f := \frac{1}{2} \| \cdot - \hat{\phi} \|^2, \quad g = \omega P(\cdot), \quad \text{and} \quad M := D.
\]
Moreover, the particular structure of this problem enables an easy computation of the ADMM iteration, as we show next.
**x-update for quadratic functions:** Since \( f \) is a quadratic function, the \( x \)-update of the ADMM and the aADMM can be obtained via the solution of a system of linear equations. More precisely, steps (2a) and (12a) are computed by solving the linear system

\[
(\text{Id} + \gamma M^T M) x^{k+1} = M^T (\gamma z^k - y^k) + \tilde{\phi},
\]

**z-update as a proximal step:** The minimization step with respect to \( z \) can be computed via the proximity operator of \( g \). Indeed, (12b) reduces to

\[
z^{k+1} = \text{prox}_{\frac{1}{\gamma} g}(M x^{k+1} + \delta^{-1} y^k) = \text{prox}_{\frac{1}{\gamma} p}(M x^{k+1} + \delta^{-1} y^k),
\]

whereas for (2b) one only replaces \( \delta \) by \( \gamma \) in (31).

We assume that the penalty function is separable in the sense that there exists \( p : \mathbb{R} \to \mathbb{R}_+ \) such that

\[
P(z) = \sum_{i=1}^{n-1} p(z_i), \quad \text{for all } z = (z_1, \ldots, z_{n-1}) \in \mathbb{R}^{n-1}.
\]

The proximal mapping of \( P \), usually referred to as thresholding or shrinkage, can be computed component-wise. The type of penalty function chosen in (30), together with the regularization parameter \( \omega \), has a significant impact on the quality of the denoised solution. In Table 1 we list three types of penalty functions and their corresponding thresholding mappings (see, e.g., [40]).

| Nickname | Penalty function | Thresholding mapping |
|----------|------------------|---------------------|
| Hard     | \( p^{(H)}(x) = \begin{cases} 0, & \text{if } x = 0, \\ 1, & \text{otherwise.} \end{cases} \) | \( \text{prox}_{\gamma p^{(H)}}(x) = \begin{cases} 0, & \text{if } |x| < \sqrt{2\gamma}, \\ \{0, x\}, & \text{if } |x| = \sqrt{2\gamma} \\ x, & \text{if } |x| > \sqrt{2\gamma} \end{cases} \) |
| Soft     | \( p^{(S)}(x) = |x| \) | \( \text{prox}_{\gamma p^{(S)}}(x) = \begin{cases} 0, & \text{if } |x| \leq \gamma, \\ \text{sign}(x)(|x| - \gamma), & \text{otherwise.} \end{cases} \) |
| Firm     | \( p^{(F)}_{\zeta}(x) := \begin{cases} |x| - \frac{x^2}{2\zeta}, & \text{if } |x| \leq \zeta, \\ \zeta, & \text{otherwise.} \end{cases} \) | \( \text{prox}_{\gamma p^{(F)}_{\zeta}}(x) = \begin{cases} 0, & \text{if } |x| \leq \gamma, \\ \text{sign}(x)(|x| - \gamma)\zeta, & \text{if } \gamma < |x| < \zeta, \\ x, & \text{otherwise.} \end{cases} \) |

**Table 1:** Three penalty functions and the corresponding thresholding mappings.

The hard penalty is associated with the \( l_0 \)-norm, it is the one to impose sparsity on the solution. Since the hard penalty is nonconvex (in fact, it is not \( \alpha \)-convex for any choice of \( \alpha \in \mathbb{R} \)), there is no guarantee for the convergence of the ADMM when applied to this problem. As an alternative, the \( l_0 \)-norm is replaced by the \( l_1 \)-norm, leading to the proximal mapping known as soft thresholding. Although convex, this penalty may yield to biased solutions when the variation of the original signal is large. In order to obtain less biased solutions, some weakly convex penalties, such as the firm thresholding [22], associated to a minimax concave penalty, arises as a tradeoff between the hard and the soft thresholdings (see Figure 1).
We observe that the firm penalty function $p_{\zeta}(F)(x)$ is weakly convex with parameter $-\frac{1}{\zeta}$. Indeed, one verifies that the function $p_{\zeta}(F)(x) + \frac{x^2}{2\zeta}$ is convex either by direct computation or via a more general argument such as [6, Theorem 5.4].

Since $f$ is 1-strongly convex, Assumption 4.1 holds whenever $\zeta \geq 4\omega$ since

$$1 - \|D\|^{2\omega} \frac{\omega}{\zeta} \geq 0 \iff \zeta \geq \|D\|^{2\omega}$$

and the fact that $\|D\| \leq 2$.

**Experiment 1: convex versus weakly convex penalties**

In our first experiment we aim to show that using a weakly convex penalty function may produce more accurate solutions than the $l_1$-norm in certain circumstances. To this end we employ generated\(^1\) block signals (piecewise constant signals) to which we add a gaussian noise with standard deviation $\sigma = 0.5$. Given a generated noisy signal, for 50 values of the penalty parameter $\omega$ equally distributed in the interval $[0, 5]$, we compute two solutions of problem $(30)$, one with respect to the soft thresholding (convex) and another with respect to the firm one (weakly convex) with $\zeta = 4\omega$. In order to measure the quality of the reconstruction of a denoised signal $x = (x_1, \ldots, x_n) \in \mathbb{R}^n$ with respect to the original signal $\phi = (\phi_1, \ldots, \phi_n) \in \mathbb{R}^n$, we employ the mean absolute error (MAE), defined by

$$\text{MAE}(x, s) = \frac{1}{n} \sum_{i=1}^{n} |x_i - \phi_i|.$$ 

The results for a signal of size $n = 256$ are shown in Figure 2(a). We see that the weakly convex penalty (firm) achieves more accurate solutions. Indeed, the MAE of the solution produced by

\(^1\)Signals were generated with the Python package PyWavelets [https://pywavelets.readthedocs.io/](https://pywavelets.readthedocs.io/)
the firm thresholding is always smaller than that of the soft thresholding, except for small values of \( \omega \) for which the quality of both solutions is deficient. In order to visualize the performance of each penalty function we plot in Figure 2(b) the denoised solutions for \( \omega = 2 \), as well as the original and the noisy signals. We see that the firm thresholding produces less biased solutions at the break points of the signal, in particular, at the break points corresponding to relatively short pieces, where the true variation of the original signal is large.

![Mean Absolute Error](image)

(a) MAE with respect to \( \omega \)  

![Original, noised and denoised signals](image)

(b) Original, noised and denoised signals for \( \omega = 2 \)

Figure 2: Denoising of a block signal of size \( n = 256 \) with soft and firm thresholdings. (a) Mean absolute error of the solutions for each penalty type with respect to the regularization parameter \( \omega \). (b) Plot of the original, noised and the two denoised signals for \( \omega = 2 \).

We repeated the experiment for different signal size \( n \) and different variance of the noise \( \sigma \). The results are similar: the firm thresholding produces solutions with less error for all large enough value of the penalty parameter \( \omega \). Due to the similarity we do not include these in this presentation.

For denosing with the soft thresholding we used the classical ADMM, whereas for the firm denoising we employed the aADMM. In this experiment we focused on the quality of the solutions produced by each penalty function in order to motivate the application of weakly convex functions, rather than the algorithm performance. In our second experiment we do focus on the performance of the algorithm.

**Experiment 2: ADMM versus aADMM**

We now examine the efficiency of the aADMM for signal denoising with weakly convex penalty. We focus on solving the total variation regularization problem \((30)\) with firm thresholding. We consider generated block signals of different sizes \( n \), noised with a Gaussian error of standard deviation \( \sigma \). For every size, we set the parameters

\[
\sigma := 0.5, \quad \omega := 2 \quad \text{and} \quad \zeta := 4\omega = 8.
\]
As noted in Remark 4.4, we can apply the classical ADMM to problem (30) with a weakly convex penalty \( P^F_\zeta \) via a convex reformulation. Thus, we compare the performance between the ADMM and the aADMM. For each \( n \in \{1000, 2000, \ldots, 10000\} \), we generated 10 noisy signals randomly. Then, for each of these noisy signals, we run the ADMM with 10 random starting points, for each \( \gamma \in \{0.2, 0.4, \ldots, 7.0\} \). At each instance, the aADDM was also launched for the same value of \( \gamma \), while the parameter \( \delta \) in the \( z \)-update step was set to

\[
\delta := \gamma - 2\beta = \gamma + \frac{2\omega}{\zeta} = \gamma + \frac{1}{2}
\]

so that the conditions for convergence in (20) hold. For both algorithms we employ the primal-dual residuals stopping criteria from Section 5.2 where we set \( \epsilon_{\text{abs}} = \epsilon_{\text{rel}} := 10^{-4} \).

The results of the experiments are shown in Figure 3: We plot the median ratio between the number of iterations required by aADMM and classical ADMM with respect to \( \gamma \), for each size. A ratio less than one indicates that the aADMM converged faster. While, on average, both algorithms behave similarly for large values of \( \gamma \), the superiority of aADMM for small values of \( \gamma \), where the ratio is always smaller than 1, is evident in this experiment.

![Figure 3](image-url)

**Figure 3**: Median of 100 ratios between the median (among 50 instances) of iterations required to converge by aADMM and classical ADMM, with respect to the penalty parameter \( \gamma \), for denoising signals of sizes 1000, 2000, \ldots, 10000 with firm thresholding.

In Figure 4 we plot the percentiles 0, 5, \ldots, 95 and 100 of the ratios between the numbers of iterations with respect to \( \gamma \) (for all sizes). This plot exhibits a small variance of the ratio, which demonstrates that the medians in Figure 3 are suitable representatives. Indeed, the curve for 95%-percentile still lies close to 1, which indicates that the aADMM is at least comparable with (or even better than) the ADMM within 95% of the times. In fact, the curve for the 70%-percentile lies entirely below 1. This implies that for all tested values of \( \gamma \) and all instances, the aADMM was at least as fast as the ADMM 70% of the time.
Finally, in order to better analyze the results, we further examine the outputs for $n = 1000$, $n = 5000$ and $n = 10000$ in Figure 5. Instead of the ratios between both algorithms, we plot the median of the number iterations required by each of the algorithms separately. On the one hand, we confirm our previous conclusions: for every fixed value of $\gamma$, the aADMM is as rapid as the classical ADMM (and much faster for small $\gamma$). On the other hand, if one was able to predict the optimal choice for $\gamma$, then both algorithms perform similarly. However, the optimal $\gamma$ is unknown.
7 Conclusions

We provided an adaptive version of the alternating directions method of multipliers for solving linearly constrained optimization problems where the objective is the sum of a weakly convex function and a strongly convex function. Convergence of our scheme was derived as dual to the convergence of the adaptive Douglas–Rachford splitting algorithm. Consequently, the theory regarding the dual relations between the classical ADMM and the classical DR algorithm have been extended to and established in the strongly-weakly convex framework. In the process we have also relaxed stronger assumptions imposed in other studies where the ADMM was applied in this framework (see Remarks 5.3 and 5.4).

The performance of our scheme was tested in some numerical experiments of signal denoising. In our experiments we observed that the aADMM outperforms the classical ADMM in terms of the required number of iterations. However, our numerical experiments are far from providing a complete computational study. A much more detailed and comprehensive numerical analysis will be the subject matter of future studies.
