We find self-adjoint extensions of the rational Calogero model in presence of the harmonic interaction. The corresponding eigenfunctions may describe the near-horizon quantum states of certain types of black holes.

PACS numbers: 03.65.-w, 04.70.Dy
Keywords: Calogero model, Self-adjoint extension, Black Holes

The dynamics of particles or fields in the near-horizon region of black holes [1,2] is often described in terms of the Calogero Model [3]. In particular, it has been shown that the existence of the near-horizon conformal symmetry [4] as well as the logarithmic correction to the black hole entropy [5] can be described in terms of the self-adjoint extension [6, 9] of the Calogero model in absence of the confining potential [2]. On the other hand, it has been argued that in certain string theoretic description of black holes, the near-horizon dynamics is governed by a many particle Calogero model in presence of the confining potential [2]. It is therefore of interest to find the quantum states of this model in presence of the self-adjoint extension. These states would be expected to encode the dynamics for such black holes.

In the following we consider the above eigenvalue equation for a sector of configuration space corresponding to a definite ordering of particles given by \( x_1 \geq x_2 \geq \cdots \geq x_N \). The translation-invariant eigenfunctions of the Hamiltonian \( \hat{H} \) can be written as

\[
\psi = \prod_{i<j} (x_i - x_j)^{a+\frac{1}{2}} \phi(r) P_k(x),
\]

where \( x \equiv (x_1, x_2, \ldots, x_N) \), \( r^2 = \frac{1}{N} \sum_{i<j} (x_i - x_j)^2 \) and \( P_k(x) \) is a translation-invariant as well as homogeneous polynomial of degree \( k(\geq 0) \) [3]. The radial part of the wavefunction satisfies the equation

\[
\tilde{H} = \left[ -\frac{d^2}{dr^2} - (1 + 2\nu)\frac{1}{r} \frac{d}{dr} + w^2 r^2 \right],
\]

\( w^2 = \frac{1}{8}\Omega^2 N \) and \( \nu = k + \frac{1}{2}(N - 3) + \frac{1}{2}N(N - 1)(a + \frac{1}{2}) \).

The Hamiltonian \( \hat{H} \) is a symmetric (Hermitian) operator on the domain \( D(\hat{H}) \equiv \{ \phi(0) = \phi'(0) = 0, \phi, \phi' \text{ absolutely continuous} \} \). However, when \( -1 < \nu < 1 \), \( \hat{H} \) is not self-adjoint in \( D(\hat{H}) \) but admits a one-parameter family of self-adjoint extensions [4, 9] labelled by \( \epsilon = e^{iz} \) where \( z \in \mathbb{R} \) (mod 2\( \pi \)). For \( \nu \neq 0 \), the spectrum is determined by the equation

\[
f(E) \equiv \frac{\Gamma \left( \frac{\nu}{2} - \frac{E}{w} \right)}{\Gamma \left( \frac{\nu}{2} - \frac{E}{w} \right)} = \xi_2 \cos \left( \frac{\epsilon}{2} - \eta_1 \right) \xi_1 \cos \left( \frac{\epsilon}{2} - \eta_2 \right),
\]

where \( \Gamma \left( \frac{\nu}{2} + \frac{1}{4w} \right) \equiv \xi_1 e^{i\eta_1} \) and \( \Gamma \left( \frac{\nu}{2} + \frac{1}{4w} \right) \equiv \xi_2 e^{i\eta_2} \). This equation is plotted in the figure below. The corresponding eigenfunctions are given by

\[
\phi(r) = Be^{-\frac{r^2}{2w^2}} U(d,c,wr^2),
\]

* Talk delivered by Kumar S. Gupta
where \( c = 1 + \nu, \ d = \frac{1 + \nu}{2w} - \frac{\nu}{4w}, \ B \) is a constant and \( U \) denotes the confluent hypergeometric function of the second kind.

For given values of the parameters \( \nu \) and \( w \), the bound state energy \( E \) is obtained from Eqn. (4) as a function of \( z \). Different choices of \( z \) thus leads to inequivalent quantizations of the many-body Calogero model. It may be mentioned that the self-adjoint extensions described above exist for all values of \( N \) and for higher "angular momentum" \( (k \neq 0) \) sectors of the theory as well.

The following features about the spectrum may be noted:

1) We have obtained the spectrum analytically when the r.h.s. of Eqn. (4) is either 0 or \( \infty \). When the r.h.s. of Eqn. (4) is 0, we get \( E_n = 2w(2n + \nu + 1) \) where \( n \) is a positive integer, corresponding to the choice of \( z = z_1 = \pi + 2\eta_1 \). Similarly, when the r.h.s. of Eqn. (4) is \( \infty \), we get \( E_n = 2w(2n - \nu + 1) \) corresponding to the value of \( z \) given by \( z = z_2 = \pi + 2\eta_2 \). For choices of \( z \) other than \( z_1 \) or \( z_2 \), the nature of the spectrum can be understood from Figure 1, which is a plot of Eqn. (4) for specific values of \( \nu, z \) and \( w \). In that plot, the horizontal straight line corresponds to the r.h.s of Eqn. (4). The energy eigenvalues are obtained from the intersection of \( f(E) \) with the horizontal straight line. Note that the spectrum generically consists of infinite number of positive energy solutions and at most one negative energy solution.

2) Contrary to the spectrum of the rational Calogero model, the energy spectrum obtained from Eqn. (4) is not equispaced for finite values of \( E \) and for generic values of \( z \). This may seem surprising with the presence of \( SU(1, 1) \) as the spectrum generating algebra in this system \[10\], which demands that the eigenvalues be evenly spaced. However, when \( z \neq z_1, z_2 \), the generator of dilatations does not in general leave the domain of the Hamiltonian invariant \[8, 11\]. Consequently, \( SU(1, 1) \) cannot be implemented as the spectrum generating algebra except for \( z = z_1, z_2 \).

It is plausible that the eigenfunctions described above would describe the near-horizon quantum states of certain types of black holes as described in Ref. \[2\]. Calculation for the corresponding density of states and entropy would be of future interest.
