ON HIGGS BUNDLES OVER SHIMURA VARIETIES OF BALL QUOTIENT TYPE

KE CHEN, XIN LU, SHENG-LI TAN, AND KANG ZUO

Dedicated to Prof. Ngaiming Mok on the occasion of his sixtieth birthday

Abstract. We prove the generic exclusion of certain Shimura varieties of unitary and orthogonal types from the Torelli locus. The proof relies on a slope inequality on surface fibration due to G. Xiao, and the main result implies that certain Shimura varieties only meet the Torelli locus in dimension zero.

1. Introduction

The Coleman-Oort conjecture, cf. [8], predicts that when the genus \( g \) is large enough, the Torelli locus \( T_g \) inside the Siegel modular variety \( A_g \) does not contain generically any Shimura subvariety of strictly positive dimension; in other words, the open Torelli locus \( T_g^0 \) does not contain any Zariski open subvariety of an arbitrary Shimura subvariety of dimension \( > 0 \) in \( A_g \). Using the André-Oort conjecture, an unconditional proof of which has recently been given in [11], this amounts to the finiteness of CM points in \( T_g^0 \) for \( g \) sufficiently large, which is also the original formulation of Coleman.

In [3] Hain has established the conjecture for a large class of Shimura subvarieties in \( A_g \) that do not contain locally symmetric divisors. In particular, it holds for Shimura subvarieties uniformized by Hermitian symmetric domains of rank at least 2. His proof makes use of rigidity property of mapping class groups, namely for an arithmetic group.

Γ coming from a simple \( \mathbb{Q} \)-group of \( \mathbb{R} \)-rank at least 2, any homomorphism from \( \Gamma \) to the mapping class group \( \Gamma_{g,r}^n \) is of finite image.

Note that the phenomenon of rigidity in [3] is also related to the metric rigidity property studied by Ngaiming Mok in [7]:

**Example 1.1.** The idea can be illustrated through the case of Hilbert modular varieties treated in [4]: assume that \( g \geq 5 \) and let \( M \subset A_g \) be the Hilbert modular subvariety parametrizing abelian varieties of dimension \( g \) with real multiplication by \( \mathcal{O}_F \), where \( F \) is a totally real field of degree \( g \) with an order \( \mathcal{O}_F \) in \( F \). Consider an extremal situation where \( M \) is not only contained in \( T_g^{\circ} \), but actually lifts to \( i : M \hookrightarrow M_g \), giving rise to a surjective pull-back \( i^* \Omega^1_{M_g} \rightarrow \Omega^1_M \). Note that \( \Omega^1_M \) is merely semi-positive, dual to the proper semi-negativity of \( \tan_M \) studied in [7], and it admits non-trivial quotients which are NOT big, which is absurd because \( \Omega^1_{M_g} \), and thus \( i^* \Omega^1_{M_g} \) as well, is already big.

On the other hand, for Shimura varieties uniformized by simple Hermitian symmetric domains of rank 1, such as those associated to \( \text{SU}(n, 1) \) and \( \text{Spin}(N, 2) \), Hodge-theoretic techniques provide complements when the rigidity property fails. In our previous work [1], we have proved the Coleman-Oort conjecture for a class of Shimura varieties of these types. The starting point is a numerical property of semi-stable fibration of surfaces over curves, which is translated, via the Simpson correspondence, into constraints on the fundamental group representations for the Shimura varieties of interest, and one concludes by Satake’s classification of rational symplectic representations. More precisely, the following inequality due to G. Xiao will play a crucial role in our study:

**Theorem 1.2** (Xiao’s inequality). Let \( f : S \rightarrow B \) be a non-isotrivial fibration of a smooth projective algebraic surface \( S \) over a smooth projective algebraic curve \( B \). Assume that \( f \) is generically smooth and its fibers are semi-stable curves of genus \( g \geq 2 \). Then holds the inequality

\[
12 \deg f_* \omega_{S/B} \geq (2g - 2 + \text{rank} A_{\text{max}}) \mu_{\text{max}}
\]

where \( \mu_{\text{max}} \) is the maximum of slopes of vector subbundles of \( \omega_{S/B} \), and \( A_{\text{max}} \subset f_* \omega_{S/B} \) is the maximal subbundle of \( f_* \omega_{S/B} \) of slope \( \mu_{\text{max}} \).

**Remark 1.3.** (1) The inequality above is slightly different from the original version of Xiao [12], where he obtains \( 12 \deg f_* \omega_{S/B} \geq (2g - 2) \mu_{\text{max}} \) and thus

\[
\frac{\text{rank} F^{1,0}}{g} \leq \frac{5}{6} + \frac{1}{6g}.
\]

The proof of the version in Theorem 1.2 is exactly the same as in [12], which is not reproduced in this paper.

(2) In [1] we have made use of the following refined form

\[
12 \deg f_* \omega_{S/B} \geq (4g - 4 - 2 \text{rank} F^{1,0}) \mu_{\text{max}}, \quad \text{and} \quad \frac{\text{rank} F^{1,0}}{g} \leq \frac{4}{5} + \frac{2}{5g},
\]

where a decomposition \( f_* \omega_{S/B} = A^{1,0} \oplus F^{1,0} \) is assumed, with \( A^{1,0} \) semi-stable and ample while \( F^{1,0} \) is the maximal flat part. Such a decomposition holds when \( B \) is constructed out of a Shimura curve contained generically in \( T_g \) due to properties of Higgs bundles.
on Shimura curves: only one single non-zero slope appears in the Harder-Narasimhan filtration of $f_*\omega_{S/B}$. The Shimura varieties studied in [1] do contain Shimura curves, while in the more general case of the present paper we can only resort to the inequality as in [Theorem 1.2] because several different slopes might be involved.

**Theorem 1.4** (Shimura varieties of SU($n,1$)-type). Let $M \subset A_V$ be a Shimura subvariety of SU($n,1$)-type defined over a totally real field $F$ of degree $d$, such that the corresponding symplectic representation is primary of type $\Lambda_m$ for some integer $m \in [1, n]$ of multiplicity $r$. Then $M$ is NOT contained generically in $T_g$ as long as the following inequality holds:

$$\frac{n + m - 1}{n} \left( \frac{n + 1}{m} \cdot d + \frac{1}{2} - \frac{1}{r} \frac{n}{m-1} \right) > 12.$$

**Remark 1.5.** The theorem above actually implies that the Shimura variety $M$ under consideration only meets the open Torelli locus $T^o_g$ at finitely many points: otherwise $M$ contains a curve $C$ which is generically contained in $T_g$, and the arguments in the proof (cf. Section 3) produces an inequality contradicting Xiao’s estimation. Our naive bound on the flat part also treats the similar phenomenon for more general Shimura varieties, cf. Proposition 2.4 and Corollary 2.5.

The theorem above is applied to the generic exclusion from the Torelli locus of some Shimura varieties of orthogonal type containing Shimura varieties of unitary type. In fact, if $h : W \times W \to \mathbb{C}$ is an Hermitian form over $\mathbb{C}$ of signature $(n,1)$, then its real part is a quadratic form of signature $(2n,2)$, and one obtains a natural equivariant embedding of the corresponding Hermitian symmetric domains. Adding suitable arithmetic constraints we expand this example into the following theorem:

**Theorem 1.6** (Shimura varieties of orthogonal types). Let $M' \subset A_V$ be a Shimura subvariety of Spin($N,2$)-type given by some Shimura datum $(G', X'; X'^+)$, namely associated to some quadratic space $(W, q)$ over a totally real field $F$ of degree $d$, of signature

- $(N, 2)$ along one fixed real embedding $\sigma = \sigma_1 : F \hookrightarrow \mathbb{R}$;
- definite along the other embeddings $\sigma_2, \ldots, \sigma_d : F \hookrightarrow \mathbb{R}$.

Assume that $M'$ contains a Shimura subvariety of SU($n,1$)-type associated to some Hermitian space $(H, h)$ over some CM quadratic extension $E$ of $F$, such that the signature of $h$ is

- $(n, 1)$ along $\sigma$;
- definite along the other embeddings $\sigma_2, \ldots, \sigma_d$;

which fits into an orthogonal direct sum decomposition $W = U \oplus \text{Res}_{E/F} H$ with $U$ some $F$-subspace of signature $(N - 2n, 0)$ along $\sigma$. If $N > 2n$ and the inclusion $M' \hookrightarrow A_V$ is defined by a symplectic representation of primary type, then $M'$ is NOT contained generically in $T_g$ as long as $d > 3 + \frac{1}{m-2(N+1)/2} - \frac{1}{2n+2}$, where $m$ is the multiplicity of the spinor representation in $W \otimes_{F,E} \mathbb{R}$ for the group Spin($N,2$), the only non-compact factor in $G^{\text{der}}(\mathbb{R})$.

In particular the inequality holds whenever $d \geq 4$; if $N > 2n+4$, then it holds for $d \geq 3$. 

The theorem deals with the case $N > 2n$, while the case $N = 2n$ is treated in detail taking care of the parity of $n$ and the primary type of symplectic representations involved, cf. Proposition 4.4.

Similar to [1], the criteria obtained involve certain representation-theoretic parameters describing the symplectic representations defining Shimura subvarieties, and they are NOT pure bounds on the genus $g$.

The paper is organized as follows. In Section 2 we collect preliminaries on Shimura subvarieties in $\mathcal{A}_g$ and prove a naive bound on the compact factors in the Mumford-Tate groups for Shimura subvarieties contained generically in the Torelli locus. Section 3 computes the slopes of certain Higgs bundles on Shimura varieties of SU$(n,1)$-type and proves Theorem 1.4. Finally in Section 4 we apply the results in Section 3 to a class of Shimura varieties of orthogonal types.

2. A naive bound for flat Higgs subbundles

In this paper Shimura varieties and Shimura subvarieties in $\mathcal{A}_g$ are connected algebraic varieties over $\mathbb{C}$, following the definitions given in [1, 5]:

Definition 2.1 (Shimura varieties). A (connected) Shimura datum is of the form $(G, X; X^+)$ consisting of

- $(G, X)$ a (pure) Shimura datum in the sense of [2];
- $X^+$ is a connected component of $X$.

Note that $X$ is a homogeneous space under $G(\mathbb{R})$ of homomorphisms $S \to G_{\mathbb{R}}$ subject to certain Hodge-theoretic constraints, with $S$ the Deligne torus $\text{Res}_{\mathbb{C}/\mathbb{R}} \mathbb{G}_m$; $X^+$ is homogeneous under $G_{\text{ad}}(\mathbb{R})^+$, and is an Hermitian symmetric domain.

Take $\Gamma \subset G(\mathbb{R})^+$ a congruence subgroup, we have the (connected) Shimura variety $M = \Gamma \backslash X^+$, where $\Gamma$ acts on $X^+$ through its image in $G_{\text{ad}}(\mathbb{R})^+$. The theorem of Baily-Borel compactification affirms that $M$ is a normal quasi-projective algebraic variety over $\mathbb{C}$, and we always assume that $\Gamma$ is torsion-free, so that $M$ is smooth and its fundamental group is identified with $\Gamma$.

The canonical projection $\varphi = \varphi_\Gamma : X^+ \to \Gamma \backslash X^+, x \mapsto \Gamma x$ is called the uniformization map. A Shimura subvariety in $M$ is given as $M' = \varphi(X'^+)$ for some connected Shimura subdatum $(G', X'; X'^+)$, namely $(G', X')$ is a Shimura subdatum of $(G, X)$ in the sense of [2] and $X'^+$ is a connected component of $X'$ contained in $X^+$. It is known that $M'$ is a closed subvariety in $M$, and its fundamental group is isomorphic to $\Gamma \cap G_{\text{det}}(\mathbb{R})^+$.

Example 2.2 (Siegel modular variety). Fix $V$ a rational symplectic space of dimension $2g$, we have the Shimura datum $(G_{\text{Sp}} V, \mathcal{H}_V; \mathcal{H}_V^+)$ where $\mathcal{H}_V^+$ is the Siegel upper half space of genus $g$. Usually we assume that $V$ comes from the standard symplectic $\mathbb{Z}$-module of discriminant 1, and thus a suitable choice of a congruence subgroup $\Gamma \subset G_{\text{Sp}} V(\mathbb{Q})$ defines Siegel modular varieties $\mathcal{A}_g = \mathcal{A}_V := \Gamma \backslash \mathcal{H}_V^+$ parameterizing principally polarized abelian varieties of dimension $g$ with level-$\Gamma$ structures.

We mainly consider Shimura subvarieties in $\mathcal{A}_V$. As is explained in [1], a Shimura subdatum $(G, X; X^+)$ defining a Shimura subvariety $M \subset \mathcal{A}_V$ gives rise to a rational symplectic representation $G \to G_{\text{Sp}} V$ satisfying Satake’s condition (H2) in the sense of
We always assume that the level structure $\Gamma$ is suitably chosen so that the inclusion $M \hookrightarrow A_g$ extends to their smooth toroidal compactifications $\overline{M} \hookrightarrow \overline{A}_g$, which joins to $M$ resp. to $A_g$ finitely many boundary divisors.

We write $T^o_g$ for the schematic image of

$$j : M_g \to A_g = A^V,$$

called the open Torelli locus, and $T_g$ for its closure, called the Torelli locus. The slope inequality of Xiao is mainly applied to the following situation:

**Proposition 2.3** (Higgs bundles for surface fibration). Let $C$ be a closed curve in $A_g$ contained generically in the Torelli locus, namely $C^o := C \cap T^o_g$ is open in $C$. Let $B^o$ be the normalization of the preimage of $C^o$ in $M_g$, giving rise to a family of curve $f^o : S^o \to B^o$ which is compactified into a surface fibration $f : S \to B$ with semi-stable fibers of genus $g$. Write $i : B \to C$ for the induced morphism from $B$ into $C$, and $V_{C}^{1,0}$ for the $(1,0)$-part of the logarithmic Higgs bundle $V_C$ on $C$ deduced from the variation of Hodge structure on $A_g$ defined by the moduli problem. Then holds the isomorphism

$$f_* \omega_{S/B} \cong i^* V_{C}^{1,0}$$

where $\omega_{S/B}$ is the relative dualizing sheaf for $f$. In particular we have the decomposition $f_* \omega_{S/B} = F_B \oplus A_B$, where $F_B$ is the semi-stable subbundle of slope 0 corresponding to the Higgs subbundle in $V_C$ given by the maximal unitary subrepresentation in of the $\mathbb{C}$-linear representation of $\pi_1(C)$ associated to $V_C$ using Simpson’s correspondence.

In the rest of this section we derive a naive bound on the flat part in the canonical Higgs bundle associated to a Shimura variety of dimension $> 0$ contained in $T_g$ generically using Xiao’s inequality.

**Proposition 2.4** (naive bound on the flat part). Let $M \subset A_g$ be a Shimura subvariety defined by a subdatum $(G, X; X^+)$, such that the derived part of the $\mathbb{Q}$-group $G$ admits an isomorphism $G^{\text{der}} = \text{Res}_{F/\mathbb{Q}} H$ for some totally real field $F$ and some semi-simple $F$-group $H$, and the representation $G^{\text{der}} \hookrightarrow \text{Sp}_V$ decomposes into

$$V = V_0 \oplus \text{Res}_{F/\mathbb{Q}} W$$

with $V_0$ a trivial subrepresentation and $H$ acting on $W$ preserving some symplectic $F$-form. Assume further that $F$ is of degree $d$ over $\mathbb{Q}$, such that:

- along $r(> 0)$ real embeddings $\sigma_1, \ldots, \sigma_r : F \hookrightarrow \mathbb{R}$, the Lie group $H(\mathbb{R}, \sigma_i)$ is compact;
- along the other $d - r(> 0)$ real embeddings $\sigma_{r+1}, \ldots, \sigma_d : F \hookrightarrow \mathbb{R}$, the Lie group $H(\mathbb{R}, \sigma_j)$ is non-compact.

Here $H(\mathbb{R}, \sigma_i)$ is the evaluation of $H$ at $\sigma_i : F \hookrightarrow \mathbb{R}$.

If $M$ is contained generically in the Torelli locus, then holds the inequality

$$\frac{r}{d} \leq \frac{5}{6} + \frac{1}{6g}.$$
Proof. The \( \mathbb{Q} \)-linear representation \( V = V_0 \oplus \text{Res}_{F/Q} W \) decomposes into

\[
V \otimes_{\mathbb{Q}} \mathbb{R} = V_0 \otimes_{\mathbb{Q}} \mathbb{R} \oplus \left( \bigoplus_{i=1}^d W \otimes_{F, \sigma_i} \mathbb{R} \right)
\]

after the base change \( \mathbb{Q} \hookrightarrow \mathbb{R} \), with \( G^{\text{der}}(\mathbb{R}) \) acting on \( V_0 \otimes_{\mathbb{Q}} \mathbb{R} \) trivially, and \( H(\mathbb{R}, \sigma_i) \) acting on \( V \otimes_{\mathbb{Q}} \mathbb{R} \) through the summand \( W \otimes_{F, \sigma_i} \mathbb{R} \). Let

\[
\mathcal{V} = \mathcal{V}_M = V_0 \oplus \bigoplus_{i=1}^d W_i
\]

be the Higgs bundle decomposition on \( \overline{M} \) according to the decomposition of

\[
V \otimes_{\mathbb{Q}} \mathbb{C} = (V \otimes_{\mathbb{Q}} \mathbb{R}) \otimes_{\mathbb{R}} \mathbb{C},
\]

where \( \mathcal{V}_0 \) corresponds to \( V_0 \) and \( \mathcal{W}_i \) corresponds to \( W \otimes_{F, \sigma_i} \mathbb{R} \otimes_{\mathbb{R}} \mathbb{C} \) respectively. Then the Higgs subbundles \( \mathcal{V}_0 \) and \( \mathcal{W}_i \) for \( i = 1, \cdots, r \) are flat as the \( G^{\text{der}}(\mathbb{R}) \)-action factors through compact Lie groups. In particular, the portion of of flat part in \( \mathcal{V} \) is at least

\[
\frac{\text{rank } \mathcal{F}^{1,0}}{\text{rank } \mathcal{V}^{1,0}} = \frac{\text{rank } \mathcal{F}}{\text{rank } \mathcal{V}} = \frac{\text{rank } \mathcal{V}_0 + \sum_{i=1}^r \text{rank } \mathcal{W}_i}{\text{rank } \mathcal{V}} \geq \frac{\sum_{i=1}^r \text{rank } \mathcal{W}_i}{\sum_{i=1}^d \text{rank } \mathcal{W}_i} = \frac{r}{d}
\]

since \( \text{rank } \mathcal{W}_i = 2 \dim_F W \) for all \( i \).

Assume that \( M \) is contained generically in \( \mathcal{T}_g \). Then the linear system of the ample line bundle of top degree automorphic forms on \( M \) produces a curve \( C \) in \( \overline{M} \) such that \( C \cap M \) is open and dense in \( C \), and up to Hecke translation we may assume further that \( C \) is contained generically in \( \mathcal{T}_g \). Restricting \( \mathcal{V}_M \) to \( C \) gives us the Higgs bundle \( \mathcal{V}_C \), which flat part \( \mathcal{F}_C \) contains the pull-back of \( \mathcal{F} \) to \( C \), hence

\[
\frac{\text{rank } \mathcal{F}_C}{\text{rank } \mathcal{V}_C} \geq \frac{\text{rank } \mathcal{F}}{\text{rank } \mathcal{V}} = \frac{r}{d}
\]

It remains to notice that the map \( i : B \rightarrow C \) is finite, and we have

\[
\text{rank } \mathcal{F}_B = \text{rank } \mathcal{F}_C
\]

for the flat part \( \mathcal{F}_B \) in \( f_* \omega_{S/B} \), hence Xiao’s inequality \textbf{Theorem 1.2} would fail for \( B \) as long as \( \frac{r}{d} > \frac{5}{6} + \frac{1}{6g} \), which is absurd. \( \square \)

Corollary 2.5. Let \( M \subset \mathcal{A}_V = \mathcal{A}_g \) be a Shimura subvariety defined by \( (G, X; X^+) \) with \( G^{\text{der}} \simeq \text{Res}_{F/Q} H \) for some semi-simple group \( H \) over a totally real field \( F \), which is compact along \( r \) real embeddings of \( F \) and non-compact along the remaining \( d - r \) embeddings, \( d \) being the degree \( [F : \mathbb{Q}] \). If \( \frac{r}{d} > \frac{5}{6} + \frac{1}{6g} \), then \( M \) only meets \( \mathcal{T}_g \) at finitely many points.

The proof is similar and immediate: otherwise one finds a curve in \( \overline{M} \) contradicting Xiao’s inequality.
3. Shimura subvarieties of $\mathbf{SU}(n,1)$-type

We first briefly recall the set-up for Shimura subvarieties of $\mathbf{SU}(n,1)$-type, which is slightly more general than the one used in [1], as we no longer require the existence of an Hermitian form over a CM field.

**Definition 3.1** (Shimura subvarieties of $\mathbf{SU}(n,1)$-type). For the fixed symplectic $\mathbb{Q}$-vector space $V$ of dimension $2g$, a Shimura subvariety of $A_V$ is said to be of $\mathbf{SU}(n,1)$-type if it is defined by a Shimura subdatum $(G, X; X^+) \subset (\mathbf{GSp}_V, H_V; H_V^+)$ such that $G^\text{der} \simeq \text{Res}_{F/\mathbb{Q}} H$ with

- $F$ is a totally real number field of degree $d$ and $H$ is a simple $F$-group;
- among the real embeddings $\sigma_1, \cdots, \sigma_d$, we have $H(\mathbb{R}, \sigma_1) \simeq \mathbf{SU}(n,1)$, and $H(\mathbb{R}, \sigma_i) \simeq \mathbf{SU}(n+1)$ for $i = 2, \cdots, d$.

We call $F$ the definition field of the datum.

Note that when $n \geq 2$, $X = X^+$ is connected. The inclusion

$$(G, X; X^+) \hookrightarrow (\mathbf{GSp}_V, H_V; H_V^+)$$

gives rise to the representation of $G$ on $V$, and from [10] we know that the restriction of this representation to $G^\text{der} = \text{Res}_{F/\mathbb{Q}} H$ is decomposed into $V = V_0 \oplus V'$ where

- $G^\text{der}$ acts on $V_0$ trivially;
- the representation $G^\text{der} \to \mathbf{GL}_V$ is the scalar restriction of an $F$-linear representation $H \to \mathbf{GL}_{W,F}$ where $W$ is an $F$-vector space carrying a symplectic $F$-form preserved by $H$.

Let $M$ be the Shimura subvariety in $A_V$ of $\mathbf{SU}(n,1)$-type in the sense above, defined by $(G, X; X^+)$, isomorphic to $\Gamma \backslash X$ for a torsion-free congruence subgroup $\Gamma \subset G^\text{der}(\mathbb{Q})^+$, and we write $\mathcal{V}$ for the Higgs bundle of the $\mathbb{C}$-PVHS on $M$ given by the moduli problem. Similar to the situation in [1] which we have also used in Section 2 for the naive bound, there exists a decomposition of Higgs bundles

$$\mathcal{V} = \mathcal{V}_0 \oplus \sum_{i=1}^d \mathcal{W}_i$$

with $\mathcal{V}_0$ a trivial Higgs bundle corresponding to $V_0$, and $\mathcal{W}_i$ the Higgs bundle associated to $W \otimes_{F,\sigma_i} \mathbb{R}$, in which the only non-flat part is given by $\mathcal{W}_1$.

According to the Satake classification over $\mathbb{R}$ cf.[9], along $\sigma_1 : F \hookrightarrow \mathbb{R}$ the base change admits a decomposition

$$\sigma_1^* W = W \otimes_{F,\sigma_1} \mathbb{R} \simeq \bigoplus_{m=1}^{n-1} \Lambda_m^\oplus r_m$$

where $\Lambda_m = \wedge^m_{\mathbb{C}} \text{Std}$ is the $m$-th exterior power of the standard representation of $\mathbf{SU}(n,1)$ on $\mathbb{C}^{n+1}$. Note that the action of $\mathbf{SU}(n,1)$ on $\Lambda_m$ preserves an Hermitian form of signature $(m, n-m)$, and $\dim_{\mathbb{R}} \Lambda_m = 2 \binom{n+1}{m}$.

In the sequel we assume for simplicity that $V$ is primary of type $\Lambda_m$ in the sense of [1, Subsection 5.2], namely $V_0 = 0$ and $\sigma_1^* W \simeq (\wedge^m \text{Std})^\oplus r$ for some multiplicity $r \geq 1$. 

We need the following fact to compute the Harder-Narasimhan filtration on certain curves, cf. [6, 7.12]:

**Lemma 3.2** (decomposition of the canonical Higgs bundle). Let $\mathcal{E}$ be the Higgs bundle on $M$ associated to the $\mathbb{C}$-representation

$\Gamma \hookrightarrow \mathbf{G}^{\text{der}}(\mathbb{R}) \to H(\mathbb{R}, \sigma_1) \xrightarrow{\text{Std}} \mathbf{GL}_C(\mathbb{C}^{n+1} \otimes_R \mathbb{C})$

(through the unique non-compact factor of $\mathbf{G}^{\text{der}}(\mathbb{R})$). Then the Hodge decomposition of $\mathcal{E}$ is of the form $\mathcal{E} = \mathcal{E}^{1,0} \oplus \mathcal{E}^{0,1}$ with

- $\mathcal{E}^{1,0} \cong \Omega_M^1 \otimes L^\vee \oplus L$;
- $\mathcal{E}^{0,1} \cong (\mathcal{E}^{1,0})^\vee = \text{Tan}_M \otimes L \oplus L^\vee$.

Here $L$ is a line bundle on $M$ such that $L \otimes (n+1) = \omega_M (= \Omega_M^n)$, and the summands in $\mathcal{E}^{1,0}$ and $\mathcal{E}^{0,1}$ are stable subbundles.

In particular, writing $S = \Omega_M^1 \otimes L^\vee$ which gives $\mathcal{E}^{1,0} = S \oplus L$, we have

$$c_1(L) = \frac{1}{n+1} c_1(\omega_M) = c_1(\Omega_M^1 \otimes L^\vee), \quad c_1(\mathcal{E}^{1,0}) = 2c_1(L) = \frac{2}{n+1} c_1(\omega_M).$$

For the $m$-th exterior power

$$\wedge^m \mathcal{E}^{1,0} = \wedge^m S \oplus \wedge^{m-1} S \otimes L,$$

we have

$$c_1(\wedge^m S) = \left(\frac{n-1}{m-1}\right) \cdot \frac{1}{n+1} c_1(\omega_M),$$

$$c_1(\wedge^{m-1} S \otimes L) = \left(2 \left(\frac{n}{m-1}\right) - \left(\frac{n-1}{m-1}\right) \right) \cdot \frac{1}{n+1} c_1(\omega_M),$$

$$c_1(\wedge^m \mathcal{E}^{1,0}) = \left(\frac{n}{m-1}\right) \cdot \frac{2}{n+1} c_1(\omega_M).$$

Similar properties hold for the canonical logarithmic extensions of these structures to $\overline{M}$ (the smooth toroidal compactification of $M$).

**Proof.** The decomposition for $\mathcal{E}$ and the first Chern classes for $S$ and $L$ are given in [6]. The claim for higher exterior powers follows from the splitting principle of Chern classes (using the facts that $c_1(\wedge^m M) = (\text{rank } M - 1) \cdot c_1(M)$ and $c_1(M' \otimes M'') = \text{rank } (M') c_1(M'') + \text{rank } (M'') c_1(M')$).

**Theorem 3.3** (exclusion of Shimura subvarieties of $\text{SU}(n,1)$-type). Let $M \subset \mathcal{A}_W = \mathcal{A}_g$ be a Shimura subvariety of $\text{SU}(n,1)$-type defined by a Shimura subdatum $(\mathbf{G}, X; \Sigma)$ as in [Definition 3.1] such that the rational symplectic representation $\mathbf{G}^{\text{der}} \hookrightarrow \text{Sp}_{W}$ is primary of type $\Lambda_m$ in the sense of [1]. Then $M$ is NOT contained generically in the Torelli locus in $\mathcal{A}_W$ as long as the following inequality holds:

$$\frac{n + m - 1}{n} \left(\frac{n+1}{m} \cdot d - \frac{2}{r^{(n-1)/m}}\right) > 12.$$
Proof. Assume on the contrary that \( M \) is contained generically in \( T_g \). Then the same construction used in Proposition 2.4 produces a curve \( C \) in the \( n \)-dimensional subvariety \( \mathcal{M}(\subset \mathcal{A}_V) \) using successive \( n - 1 \) hyperplane sections of a fixed very ample power \( \omega^N_M \) of the automorphic line bundle on \( M \), such that \( C^n = C \cap T_g^c \) is open and dense in \( C \), which gives rise to a surface fibration \( f : S \to B \) and a finite morphism \( i : B \to C \).

The logarithmic Higgs bundle \( \mathcal{V}^{1,0} \) on \( \mathcal{M} \) defined by the moduli problem \( M \hookrightarrow \mathcal{A}_V \) already admits the following filtration

\[
0 = \mathcal{V}_0 \subsetneq \mathcal{V}_1 \subsetneq \mathcal{V}_2 \subsetneq \mathcal{V}_3 = \mathcal{V}^{1,0}
\]

where:
- \( \mathcal{V}_1 \) is the summand \((\wedge^{m-1} S \otimes \mathcal{L})^\oplus_r \) in \( \mathcal{W}_1 \);
- \( \mathcal{V}_2 = \mathcal{W}_1 \simeq \mathcal{V}_1 \oplus (\wedge^{m} S)^\oplus_r \);
- \( \mathcal{V}_3 = \mathcal{V}^{1,0} \) only differs from \( \mathcal{W}_1 \) by a direct summand \( F \) flat of degree zero.

The graded quotients of this filtration are already semi-stable. Computing their degrees over \( \mathbb{C} \) we find that the maximal slope in \( \mathcal{V}_3 \) is realized on \( \mathcal{V}_1 \)

\[
\mu(\mathcal{V}_1) = \mu(\wedge^{m-1} S \otimes \mathcal{L}) = \frac{2^m n}{m-1} - \frac{(n-1)}{m-1} \cdot d_C,
\]

with the constant \( d_C = \frac{n^{n-1}}{n+1} c_1(\omega_M)^n \) as we have used the fixed very ample line bundle \( \omega^N_M \) on \( M \) which extends to \( \omega^N_M \) on \( \mathcal{M} \). Note also that

\[
\deg(\mathcal{V}^{1,0}_C) = r \deg(\wedge^m \mathcal{E}^{1,0}) = 2r \left( \frac{n}{m-1} \right) \cdot d_C,
\]

\[
g = \frac{1}{2} \dim \mathcal{V} = rd \left( \frac{n+1}{m} \right),
\]

and that the maximal slope part is \( \mathcal{V}_1 \simeq (\wedge^{m-1} S \otimes \mathcal{L})^\oplus_r \), which is of rank \( r \left( \frac{n}{m-1} \right) \).

Passing from \( C \) to \( B \) only changes \( d_C \) (resp. \( \mu(\mathcal{V}_1) \)) to \( d_B \) (resp. \( \mu(\iota^* \mathcal{V}_1) \)) by a positive multiple \( \deg \iota \), and Xiao’s inequality gives us

\[
12 \cdot 2r \left( \frac{n}{m-1} \right) \cdot d_B \geq \left( 2rd \left( \frac{n+1}{m} \right) - 2 + r \left( \frac{n}{m-1} \right) \right) \cdot \left( 2 - \frac{(n-1)}{m-1} \right) \cdot d_B,
\]

which is

\[
\frac{n + m - 1}{n} \left( \frac{n+1}{m} d + 1 + \frac{1}{r \left( \frac{n}{m-1} \right)} \right) \leq 12
\]

and hence the generic exclusion when the inequality above fails. \( \square \)

For example, when \( m = 1 \), we obtain the generic exclusion for such Shimura subvarieties satisfying

\[
(n + 1)d > \frac{23}{2} + \frac{1}{r}
\]

which is
\( (n+1)d \geq 13 \) when \( r = 1, 2 \); this is, for example, the case when the symplectic representation is directly obtained as the imaginary part of an Hermitian form of signature \((n, 1)\) over some CM quadratic extension \(E/F\), and \( g = d(n+1) \);

\( (n+1)d \geq 12 \) when \( r \geq 3 \); this is the same as the inequality \( d(n+1) \geq 12 \) given in [\( \mathbb{H} \)] under more restrictive assumptions.

4. Shimura varieties of orthogonal type

In this section we consider a class of Shimura varieties of orthogonal type containing Shimura subvarieties of \( SU(n, 1) \)-type. Recall the following:

**Definition 4.1** (Shimura subvarieties of orthogonal type). A Shimura subvariety of orthogonal type, or more precisely, of \( Spin(N, 2) \)-type, in \( \mathcal{A}_V \) is defined by a subdatum \((G, X; X^+)\) such that \( G^{der}(\mathbb{R}) \cong Spin(N, 2) \times Spin(N+2)^{d-1} \) for some \( d \). Here \( Spin(a, b) \) is the spin group of the standard quadratic space \( \mathbb{R}^{a+b} \) of signature \((a, b)\).

The Hermitian symmetric domain \( X \) above is the one associated to \( Spin(N, 2) \), and we often make use of the following two equivalent descriptions of \( X \):

1. \( X \) is the open subset of two-dimensional negative definite \( \mathbb{R} \)-subspaces in \( \mathbb{R}^{N+2} \) in the Grassmannian \( \text{Gr}(2, \mathbb{R}^{N+2}) \);
2. \( X \) is the open subset of negative definite isotropic \( \mathbb{C} \)-lines in \( \mathbb{P}(\mathbb{C}^{N+2}) \), namely those \( \mathbb{C}v \) such that \( b(v, \overline{v}) = 0 \) and \( b(v, \overline{v}) < 0 \) for \( b \) the quadratic form of signature on \( \mathbb{R}^{N+2} \) extended to \( \mathbb{C}^{N+2} \); in particular \( X \) is an open subset of the quadric defined by \( b \) in \( \mathbb{P}(\mathbb{C}^{N+2}) \).

The equivalence between (1) and (2) is well-known: starting with \( u, u' \in \mathbb{R}^{N+2} \) which are negative definite and orthogonal to each other, we can choose a suitable \( J \in \mathbb{C}^\times \) purely imaginary so that \( v = u + Ju' \) defines a line in (2); conversely, given a line \( \mathbb{C}v \) in (2), one produces a pair of negative definite vectors \((u, u')\) orthogonal to each other giving rise to a negative definite \( \mathbb{R} \)-plane in (1).

The two descriptions above also give us a natural equivariant embedding of Hermitian symmetric domains: if \((V, q)\) is a quadratic space of signature \((N, 2)\) over \( \mathbb{R} \), and \( U \subset V \) is a positive definite subspace of dimension \( N - 2n(\geq 0) \), such that the restriction of \( q \) to the orthogonal complement of \( U \) in \( V \) is the real part of some Hermitian space \((W, \overline{b})\) of signature \((n, 1)\), then we have a natural inclusion of semi-simple Lie groups \( SU(W, h) \hookrightarrow SO(V, q) \) inducing an equivariant holomorphic embedding of the corresponding Hermitian symmetric domains \( X(W, h) \hookrightarrow X(V, q) \), sending a negative definite \( \mathbb{C} \)-line in \( X(W, h) \) to the associated negative definite \( \mathbb{R} \)-plane in \( X(V, q) \). Note that this inclusion actually factors through

\[
SU(W, h) \hookrightarrow SO(W, b) \hookrightarrow SO(V, q)
\]

and

\[
X(W, h) \hookrightarrow X(W, b) \hookrightarrow X(V, q),
\]

where we write \( b \) for the real part of \( h \), equal to the restriction of \( q \) to \( W \) as a real subspace of \( V \). Also the inclusions \( SU(W, h) \) into special orthogonal groups lift into homomorphisms into the corresponding spin groups, because special unitary groups are simply connected.
In this section we are only interested in the Coleman-Oort problem for Shimura varieties of \( \text{Spin}(N,2) \)-type containing Shimura varieties of \( \text{SU}(n,1) \)-type. We start with the case \( N = 2n \) before entering the general case where \( N > 2n \).

Let \((W, h)\) be an Hermitian space over a CM field \( E \), and write \( F \) for the totally real part of \( E \). Assume that the signature of \( h \) is:

- \((n,1)\) along one real embedding \( \sigma : F \hookrightarrow \mathbb{R} \);
- definite along the other embeddings \( \sigma_2, \cdots , \sigma_d : F \hookrightarrow \mathbb{R} \)

with \( d = [F : \mathbb{Q}] \). We also have the real part of \((W,h)\), namely \((U,q)\) with \( U = \text{Res}_{E/F} W \) and \( q = \text{tr}_{E/F} h \). Write \( H = \text{SU}(W,h) \) for the special unitary \( F \)-group associated to \((W,h)\), contained in \( H' = \text{Spin}(U,q) \) the spin \( F \)-group of \((U,q)\). Let \( M' \subset A_V = A_g \) be a Shimura subvariety of \( \text{Spin}(2n,2) \)-type, i.e. defined by a Shimura subdatum \((G', X^r; X^{t+})\) with \( \text{G}^\text{der} = \text{Res}_{F/\mathbb{Q}} H' \), which contains a Shimura subvariety \( M' \) of \( \text{SU}(n,1) \)-type defined by a Shimura subdatum \((G, X; \mathbb{C})\) with \( \text{G}^\text{der} = \text{Res}_{F/\mathbb{Q}} H \).

We have used spinor representations in \( \Pi \):

- the spinor representations of the Lie group \( \text{Spin}(2n,2) \) are \( P_+ \) and \( P_- \): choose any splitting of \( \mathbb{C}^{2n+2} \) into \( T \oplus T^\vee \) such that the quadratic form is equivalent to the pairing
  \[
  ((u, u^\vee), (v, v^\vee)) \mapsto u^\vee(v) + v^\vee(u)
  \]
  we have \( P_+ = \wedge^+ T := \wedge^\text{even} T \) and \( P_- = \wedge^- T := \wedge^\text{odd} T \cong P_+^\vee \), both of dimension \( 2^n \) over \( \mathbb{C} \).

We need to find suitable splitting for \((U,q)\), at least over \( \mathbb{C} \), using \((W,h)\). Consider the following lemma for the quadratic extension \( \mathbb{C}/\mathbb{R} \), in which we temporarily use \((U,q)\) and \((W,h)\) to denote the quadratic and Hermitian forms involved:

**Lemma 4.2.** Let \( h : W \times W \to \mathbb{C} \) be an Hermitian form over \( \mathbb{C} \), with real part \( q : U \times U \to \mathbb{R} \), and \( q_c : U_c \times U_c \to \mathbb{C} \). Then \( U_c \) admits a natural splitting by \( W \hookrightarrow U_c = W \otimes_{\mathbb{R}} \mathbb{C} \), and \( U_c \cong W \oplus \bar{W} \) with respect to the real structure on \( U_c \) given by \( U \).

**Proof.** We may diagonalize \((W,h)\) into direct sums of one dimensional \( \mathbb{C} \)-spaces, and reduce to the case when \( \dim_{\mathbb{C}} W = 1 \): \( W = \mathbb{C} w \) for some basis \( w \), and \( h(zw, z'w) = c\bar{z}z' \) for \( z, z' \in \mathbb{C} \) and \( c \in \mathbb{R}_\times \). Thus \( U \) admits a basis \((w, iw)\) for a fixed choice \( i = \sqrt{-1} \), and \( q = \text{tr}_{\mathbb{C}/\mathbb{R}} h \) sends \((aw + biw, a'w + b'iw)\) to \( c(aa' + bb') \). It suffices to choose the splitting to be

\[
W \hookrightarrow U_c = W \otimes_{\mathbb{R}} \mathbb{C}, \ w \mapsto w \otimes (1 + i)
\]

in which case \( \bar{W} \) is simply \( W \otimes (1 - i) \). \( \square \)

Return to the general setting over a CM field \( E/F \). Evaluate the inclusion \( H = \text{SU}(W,h) \hookrightarrow H' = \text{Spin}(U,q) \) at \( \sigma = \sigma_1 : F \hookrightarrow \mathbb{R} \), we get \( \text{SU}(n,1) \hookrightarrow \text{Spin}(2n,2) \).

The \( \mathbb{C} \)-representations \( P_\pm \cong \wedge^\pm (W_c) \) of \((H(\mathbb{R}), \sigma)\) restricts to sums of wedge product \( \mathbb{C} \)-representations of \((H(\mathbb{R}), \sigma)\):

**Lemma 4.3.** Let \( M \hookrightarrow M' \) be the inclusion of a Shimura variety of \( \text{SU}(n,1) \)-type into a Shimura variety of \( \text{Spin}(2n,2) \)-type associated to \( H \hookrightarrow H' \) as above. Consider the
Higgs bundles $\mathcal{P}_\pm$ on $M'$ associated to the spinor representation $P_\pm$ of $H'(\mathbb{R}, \sigma)$. Then the restriction of $\mathcal{P}_\pm$ to $M$ decomposes into

$$\mathcal{P}_+ = \bigoplus_{m \text{ even}} \mathcal{E}_m, \quad \mathcal{P}_- = \bigoplus_{m \text{ odd}} \mathcal{E}_m$$

with $\mathcal{E}_m$ the Higgs bundle associated to the $m$-th exterior power $\Lambda_m$ of the representation $G^\text{der}(\mathbb{R}) \to H(\mathbb{R}, \sigma_1) \xrightarrow{\text{Std}} GL_{n+1}(\mathbb{C})$.

In particular, $\mathcal{E}_1 = \mathcal{E}$ and $\mathcal{E}^{1,0} = S \otimes L$, and $\mathcal{E}_m^{1,0}$ decomposes into the direct sum of $\wedge^m S$ and $\wedge^{m-1} S \otimes L$, whose ranks and Chern classes are given as in Lemma 3.2. Take $C$ a generic curve in $\overline{M}$ produced from the linear system of $\omega_M^n$ a fixed very ample power of $\omega_M$, the slopes of these summands on $C$ are as follows:

$$\mu(\wedge^m S_C) = \frac{m}{n} d_C, \quad \mu(\wedge^{m-1} S_C \otimes L_C) = \frac{2n - m}{n} d_C$$

for $m = 1, \ldots, n$, with $d_C = \frac{\lambda^{n-1}}{n+1} c_1(\omega_M^n)^n$. We also have $c_1(\mathcal{E}_0^{1,0}) = 0$ and $c_1(\mathcal{E}_n^{1,0}) = \frac{2}{n+1} c_1(\omega_M)$, and thus $\mu(\mathcal{E}_0^{1,0}) = 0$ and $\mu(\mathcal{E}_n^{1,0}) = 2d_C$.

The proof is immediate after Lemma 3.2.

The following proposition takes care of the inclusion $SU(n, 1) \hookrightarrow Spin(2n, 2)$ in a natural arithmetic setting. Note that the case (1) is singled out for later use in Theorem 4.5.

**Proposition 4.4** (restriction on the real part). Let $M' \subset A_V = A_g$ be a Shimura subvariety of $Spin(2n, 2)$-type, containing a Shimura subvariety $M \subset M'$ of $SU(n, 1)$-type in the sense above. Assume that the symplectic representation $G^\text{der} \hookrightarrow Sp_V$ defining $M' \hookrightarrow A_V$ admits no trivial subrepresentations. If $M'$ is contained generically in $T_g$, then the following hold:

1. If $P_+$ and $P_-$ appear with equal multiplicity $r$, then $d \leq 3 + 2^{-n-1}(\frac{1}{r} - \frac{1}{2})$;
2. If $M' \hookrightarrow A_V$ is primary of type $P_-$ of multiplicity $r$, then along the parity of $n$ we have:
   - $d \leq 3 + 2^{-n}(\frac{1}{r} - \frac{1}{2})$ when $n$ is even;
   - $d \leq \frac{6n}{2n+1} + 2^{-n}(\frac{1}{r} - \frac{1}{2})$ when $n$ is odd;
3. If $M' \hookrightarrow A_V$ is primary of type $P_+$ of multiplicity $r$, then along the parity of $n$ we have:
   - $d \leq \frac{3n}{n+1} + 2^{-n}(\frac{1}{r} - \frac{1}{2})$ when $n$ is even;
   - $d \leq 3 + 2^{-n}(\frac{1}{r} - \frac{1}{2})$ when $n$ is odd.

**Proof.** We have $G^\text{der} = \text{Res}_{F/Q} H$ and $G^\text{der} = \text{Res}_{F/Q} H'$, and the inclusion $G' \hookrightarrow Sp_V$ is restricted from $H' \hookrightarrow Sp_W$, where $W$ is an $F$-symplectic space, so that $V \simeq \text{Res}_{F/Q} W$ and the canonical logarithmic Higgs bundle $\mathcal{V} = V_{M'}$ admits a decomposition $\mathcal{V} = \oplus_{i=1, \ldots, q} \mathcal{W}_i$ with $\mathcal{W}_i$ corresponds to the action of $G^\text{der}(\mathbb{R})$ on $W \otimes_{F, \sigma_i} \mathbb{R}$ through $H'(\mathbb{R}, \sigma_i)$. In particular, the $(1, 0)$-parts $\mathcal{W}_2^{1,0}, \ldots, \mathcal{W}_d^{1,0}$ are already flat.

Similar to Theorem 3.3, we may assume that a generic curve $C$ is chosen in $\overline{M}'$ such that $C$ is contained generically in $T_g$ and lifts to a semi-stable surface fibration $f : S \to B$ together with a finite morphism $i : B \to S$ satisfying Proposition 2.3.
(1) In this case we have
\[ W \otimes F_{,r} \mathbb{R} \simeq (P_+ \oplus P_-)^{\oplus r} \simeq (\wedge (\mathcal{C}^{n+1}))^{\oplus r} \]
for some multiplicity \(r\), and thus \( \mathcal{W}_1^{1,0} \simeq (\oplus_{m=0}^{n+1} \mathcal{E}_m^{1,0})^{\oplus r} \). Therefore the maximal slope in \( \mathcal{V}_C^{1,0} \) the restriction to \( C \) is given by
\[ \mu_{\text{max}} = \mu((\mathcal{E}_n^{1,0})^{\oplus r}) = \mu(\mathcal{E}_n^{1,0}) = 2d_C \]
with \((\mathcal{E}_n^{1,0})^{\oplus r}\) of rank \(r\), while deg \( \mathcal{V}_C^{1,0} = \deg \mathcal{W}_1^{1,0} = r \sum_m \deg(\mathcal{E}_m^{1,0}) = r \cdot 2^{n+1}d_C \). and the flat part is
\[ (\wedge (\mathcal{E}_n^{1,0})^{\oplus r}) = \mathcal{W}_1^{1,0} \oplus \cdots \oplus \mathcal{W}_d^{1,0}. \]
Here we have used the same constant \(d_C\) as in Theorem \(\ref{thm:2} \). Passing to \( B \) using \( i : B \to C \), the slopes and degrees only differ by a common multiple \(d(i)\), namely one replaces the constant \(d_C\) by \(d_B = \deg(i)d_C\).

When \(M'\) is contained generically in \(T_g\), we may choose \(C \in \overline{M} \subset \overline{M}\) such that \(C\) is contained generically in \(T_g\), so that Xiao’s inequality for \(f : S \to B\) gives
\[ 12 \cdot 2^{n+1}r \geq (2 \cdot 2^{n+1}rd - 2 + r)2 \]
which is \(d \leq 3 + 2^{n+1}(\frac{1}{r} - \frac{1}{2})\).

(2) In this case \( \mathcal{V}_C^{1,0} = \mathcal{W}_1^{1,0} \oplus \cdots \mathcal{W}_d^{1,0} \) is of rank \(rd \cdot 2^n\), with \( \mathcal{W}_d^{1,0}, \cdots, \mathcal{W}_d^{1,0}\) flat, and \( \mathcal{W}_C^{1,0} \simeq (\mathcal{P}_+^{1,0})^{\oplus r}\) contains no flat part, and it already contains \((\mathcal{E}_1^{1,0})^{\oplus r}\) of slope \((2 - \frac{1}{n})d_C\), which is:

(2-1) maximal when \(E_{n+1,C}\) does not contribute, namely \(n\) is odd, and in this case the maximal slope is realized on \(L^{\oplus r}\) contained in \((\mathcal{E}_1^{1,0})^{\oplus r}\), of rank \(r\);

(2-2) strictly smaller than the maximal slope \(2d_C = \mu(E_{n+1,C})\) when \(n\) is even, and the maximal slope is realized on \((\mathcal{E}_{n+1,C}^{1,0})^{\oplus r}\) of rank \(r\).

Note that \( \mathcal{W}_C^{1,0} \simeq (\mathcal{P}_-^{1,0})^{\oplus r}\) is of rank \(2^n r\) and degree \(2^{n+1}d_C\), hence Xiao’s inequality implies:

(2-1) when \(n\) is odd: \(12 \cdot 2^n r \geq (2^{n+1}r - 2 + r)(2 - \frac{1}{n})\), which is \(d \leq \frac{6n}{2n-1} + 2^{n-1}(\frac{1}{r} - \frac{1}{2})\);

(2-2) when \(n\) is even: \(12 \cdot 2^n r \geq (2^{n+1}r - 2 + r) \cdot 2\), which is \(d \leq 3 + 2^{n-1}(\frac{1}{r} - \frac{1}{2})\).

(3) In this case \( \mathcal{W}_C^{1,0} \simeq (\mathcal{P}_-^{1,0})^{\oplus r}\) is of rank \(2^n r\). Along the parity of \(n\) we have:

(3-1) when \(n\) is even: the maximal slope comes from the summand \(\mathcal{S}_C \otimes L_C\) in \(\mathcal{E}_2^{1,0}\), which is \((2 - \frac{2}{n})d_C\) of rank \(rn\), and Xiao’s inequality becomes
\[ 12 \cdot 2^n r \geq (2^{n+1}r - 2 + rn)(1 - \frac{1}{n}) \cdot 2, \]
namely \(d \leq \frac{6n}{2n-1} + 2^{n-1}(\frac{1}{r} - \frac{2}{2})\) (note that \(n \geq 2\)).

(3-2) when \(n\) is odd: the maximal slope comes from the summand \(\mathcal{E}_{n+1,C}^{1,0}\), which is \(2d_C\) of rank \(r\), and similar to the case (2-2), Xiao’s inequality is \(12 \cdot 2^n r \geq (2^{n+1}r - 2 + r) \cdot 2\), namely \(d \leq 3 + 2^{n-1}(\frac{1}{r} - \frac{1}{2})\).
In particular, when \( r \geq 3 \), the generic exclusion of \( M \) holds whenever \( d \geq \frac{3n}{n-1} \) for \( n \) even and \( d \geq \frac{3n}{2n-1} \) for \( n \) odd, which are slightly finer than the bound \( d \geq 6 \) given in [1].

We proceed to the remaining case when \( N > 2n \):

**Theorem 4.5** (generic exclusion of Shimura varieties of orthogonal types). Let \( M' \subset A_V \) be a Shimura variety of \( \text{Spin}(N, 2) \)-type which contains a Shimura subvariety \( M \) of \( \text{SU}(n, 1) \)-type in the sense above, namely \( M' \) is associated to some quadratic space \((W, q)\) over some CM field \( E/F \) subject to the constraints of signature used in this section, and let \( U \) be a positive definite subspace of signature \((N - 2n, 0)\), whose orthogonal complement is the real part of some Hermitian space \((H, h)\) over \( E/F \) giving rise to the Shimura subvariety \( M \) mentioned above.

Assume that the symplectic representation defining \( M' \hookrightarrow A_V \) is primary. Then \( M' \) is NOT contained generically in \( T_g \) as long as \([F : \mathbb{Q}] > 3 + \frac{1}{m(2(n+1)/2)} - \frac{1}{2n-2}\), where \( m \) is the multiplicity of the spinor representation in \( W \otimes_{E,F} \mathbb{R} \) for the group \( \text{Spin}(N, 2) \).

**Proof.** Recall the behavior of spinor representations to spin subgroups used in [1], where we consider the case over \( \mathbb{C} \) for simplicity:

- the restriction of the spinor representation \( P \) of \( \text{Spin}(2k + 1) \) to \( \text{Spin}(2k) \), using an orthogonal decomposition of the form \( \mathbb{C}^{2k+1} = L \oplus \mathbb{C}^{2k} \) for some line \( L \), is the direct sum of \( P_+ \) and \( P_- \), the two half-spin representations of \( \text{Spin}(2k) \);
- similarly, the restrictions of \( P_+ \) and \( P_- \) of \( \text{Spin}(2k + 2) \) to \( \text{Spin}(2k + 1) \) are both isomorphic to the spinor representation of \( \text{Spin}(2k + 1) \) as long as the restriction comes from an orthogonal decomposition \( \mathbb{C}^{2k+2} = L \oplus \mathbb{C}^{2k+1} \) by some line \( L \).

In our setting, the condition \( N - 2n > 0 \) refines the inclusion \( W \supset \text{Res}_{E/F} H \) into \( W \supset W' \supset \text{Res}_{E/F} H \) with \( W' \) of dimension \( 3 + 2n \) over \( F \), such that

- \( W = U' \oplus W' \) is an orthogonal direct sum decomposition with \( U' \) of signature \((N - 2n - 1, 0)\) along \( \sigma \);
- \( W' = L \oplus \text{Res}_{E/F} H \) is an orthogonal direct sum decomposition with \( L \) a positive definite line.

The inclusion of Shimura varieties \( M \subset M' \) is thus refined into \( M \subset M'' \subset M' \) with \( M'' \) the Shimura variety of \( \text{Spin}(2n + 1, 2) \)-type associated to \((W', q|_{W'})\), and we write \((G'', X'', X''^+)\) for the corresponding Shimura subdatum of \((\text{GSp}_V, \mathcal{H}_V; \mathcal{H}_V^+)\). Since \( M' \hookrightarrow A_V \) is defined by some symplectic representation \( G_{\text{der}} \hookrightarrow \text{Sp}_V \) primary of spinor type, its restriction to \( G_{\text{der}} \hookrightarrow \text{Sp}_V \) is primary of spinor type, namely it is the scalar restriction from \( \rho : H'' \hookrightarrow \text{Sp}_{V''} \) along \( F \) over \( Q \), where \( H'' \) is the spin \( F \)-group of \( W'' \) and \( V'' \) is an \( F \)-symplectic space such that \( V = \text{Res}_{F/Q} V'' \) and the base change of \( \rho \) along \( \sigma : F \hookrightarrow \mathbb{R} \) decomposes into a direct sum of copies of the unique spinor representation \( P \) for \( \text{Spin}(2n + 1, 2) \).

We have explained that the restriction of \( P \) to \( \text{Spin}(2n, 2) \) is the direct sum of the two half-spin representations \( P_- \) and \( P_+ \) of equal multiplicity, hence it suffices to apply **Proposition 4.4**(1) to the further inclusion \( \text{SU}(n, 1) \subset \text{Spin}(2n, 2) \subset \text{Spin}(2n + 1, 2) \) to deduce the bound \( d = [F : \mathbb{Q}] > 3 + 2^{n-1}(\frac{1}{2} - \frac{1}{2}) \) from Xiao’s inequality.

It remains to make precise the multiplicity \( r \) along the parity of \( N \). Assume that the inclusion \( M' \hookrightarrow A_V \) is primary of multiplicity \( m \): in other words, the rational symplectic
representation defining $M' \hookrightarrow A_V$ is the scalar restriction of some $F$-linear symplectic representation $H \to \text{Sp}_W$, and $W \otimes_{F,\sigma} \mathbb{R}$ is isomorphic to $m$-copies of the spinor representation of $\text{Spin}(N, 2)$.

- If $N = 1 + 2N' > 2n$ is odd, with $N' \geq n$, then there exists only one spinor representation $P'$ for $H'([\mathbb{R}, \sigma]) \simeq \text{Spin}(1+2N', 2)$, and its restriction to $H''([\mathbb{R}, \sigma]) \simeq \text{Spin}(2n, 2)$ is isomorphic to $2^{N'-n}$ copies of $P_+ \oplus P_-$. Since $P'$ is of multiplicity $m$ in $W \otimes_{F,\sigma} \mathbb{R}$, this gives $r = m \cdot 2^{N'-n}$ for the multiplicity of $P_+ \oplus P_-$ in the representation of $H''([\mathbb{R}, \sigma])$.

- If $N = 2N' > 2n$ is even, with $N' > n$, then either of the two half-spin representations $P'_+$ and $P'_-$ of $\text{Spin}(2N', 2)$ restricts to the unique spinor representation of $\text{Spin}(2N' - 1, 2)$ and further to $2^{N'-n-1}$ copies of $P_+ \oplus P_-$ of $\text{Spin}(2n, 2)$, and one obtains $r = m \cdot 2^{N'-n-1}$ for the multiplicity of $P_+ \oplus P_-$ in the representation of $H''([\mathbb{R}, \sigma])$.

Hence the multiplicity is always $r = m \cdot 2^{[(N-1)/2] - n} = m \cdot 2^{[(N+1)/2] - n-1}$, with $m$ the multiplicity of $W$, and the proof is completed. \hfill \Box

\section*{Acknowledgement}

It is our pleasure and honor to dedicate this work to Prof. Ngaiming Mok on his sixtieth anniversary. Prof. Mok has been well-known for his contribution to complex differential geometry and algebraic geometry, and his work has seen growing influences on young geometers. We congratulate him sincerely at this occasion, and wish him a fruitful career yet to come.
