Abstract

We describe algorithms which address two classical problems in lattice geometry: the lattice covering and the simultaneous lattice packing-covering problem. Theoretically our algorithms solve the two problems in any fixed dimension $d$ in the sense that they approximate optimal covering lattices and optimal packing-covering lattices within any desired accuracy. Both algorithms involve semidefinite programming and are based on Voronoi's reduction theory for positive definite quadratic forms, which describes all possible Delone triangulations of $\mathbb{Z}^d$.

In practice, our implementations reproduce known results in dimensions $d \leq 5$ and in particular solve the two problems in these dimensions. For $d = 6$ our computations produce new best known covering as well as packing-covering lattices, which are closely related to the lattice $E_6$. For $d = 7, 8$ our approach leads to new best known covering lattices. Although we use numerical methods, we made some effort to transform numerical evidences into rigorous proofs. We provide rigorous error bounds and prove that some of the new lattices are locally optimal.

1 Overview

Two classical problems in the geometry of numbers are the determination of the most economical lattice sphere packings and coverings of the Euclidean $d$-space $E^d$. In this paper we describe algorithms for the lattice covering and the simultaneous lattice packing and covering problem (lattice packing-covering problem in the sequel).

Roughly speaking, both problems are concerned with the most economical way to cover $E^d$. In the case of the lattice covering problem, the goal is to maximize the volume of a fundamental domain in a lattice covering with unit spheres. Roughly speaking, we want to minimize the number of unit spheres which are needed to cover arbitrarily large but finite regions of $E^d$. The objective of the lattice packing-covering problem is to maximize the minimal distance between lattice points in a lattice covering with unit spheres.

The aim of this paper is to give an introduction to the mathematical tools that allow us, at least in theory, to solve the two problems computationally. For a fixed dimension $d$, our algorithms approximate optimal covering lattices and optimal packing-covering lattices within any desired accuracy. In this overview we want to describe the structure of the paper.

The basic concepts and notations, which we use throughout the paper, are in Section 2. There we also give a precise definition of the two problems under consideration. The reader familiar with sphere packings and coverings, as well as lattices and their relation to positive definite quadratic forms, may skip this section.

In Section 3 we review known results and the history of the lattice covering problem, and in Section 4 we review known results and the history of the packing-covering problem.

Our algorithms as well as the known results by other authors are mainly based on a reduction theory for positive definite quadratic forms by Voronoi. We give a detailed description of this main ingredient in Section 5 with a special focus on computational implementability.

The other main tool comes from convex optimization theory. Semidefinite programming problems and determinant maximization problems are briefly described in Section 6. We describe how duality theory together with rational approximations can be used to provide rigorous error bounds. Both problems have in common that one has to minimize a convex function on variables that satisfy some linear matrix inequalities (LMIs).

In Section 7 we describe how the constraint that a lattice gives a unit sphere covering can be modeled by LMIs.

In Section 8 we combine these tools and attain algorithms which theoretically solve the two problems under consideration.

Due to a combinatorial explosion of the number of different Delone triangulations, our implementations of the algorithms only give complete solutions for $d \leq 5$. Moreover, the convex optimization algorithms we used are interior point methods and so yield only approximations. Therefore, in Section 9 we collect some mathematical tools which allow us to determine exact results from these approximations. In particular we can test computationally whether or not a given positive definite quadratic form gives a locally optimal solution. In the case of the lattice packing-covering problem, we can test if such a solution is isolated.

In order to run a heuristic search for good lattices, it is necessary to have local lower bounds that we can compute fast. We describe one class of such bounds depending on the methods of inertia in Section 10 which we used to find new lattices in dimension 6.

Both problems have been previously solved only for dimensions $d < 5$. Our implementations not only verify all of these results, but also attain additional information on locally optimal solutions for $d = 5$. Moreover, we find new best known lattices for both problems in dimension 6, 7, and 8. In particular, we answer an open question by Ryshkov. In Section 11 we report on our results. There we distinguish between conjectures for which we only have numerical evidence and theorems for which we have rigorous proofs.
2 Basic Concepts and Notations

In this section we fix the notation we use throughout this paper. We refer the reader to [BR79], [GL87] and [CS88] for further information about the introduced concepts. The reader familiar with sphere packings and coverings, as well as lattices and their relation to positive definite quadratic forms, may skip this section.

Let \( E^d \) be a \( d \)-dimensional Euclidean space equipped with inner product \( \langle \cdot, \cdot \rangle \), norm \( \| \cdot \| \) and unit ball \( B^d = x \in E^d : \|x\| \leq 1 \). A lattice \( L \) is a discrete subgroup in \( E^d \). From now on we assume that all lattices \( L \) have full rank \( d \); that is, there exists a regular matrix \( A \in GL_d(\mathbb{R}) \) with \( L = AZ^d \). The columns of the matrix \( A \) are called a basis of \( L \). All bases of \( L \) are of the form \( A U \) with \( U \in GL_d(\mathbb{Z}) \). Thus, the determinant \( \det(L) = \det(A) > 0 \) of the lattice \( L \) is well defined. We say that two lattices \( L \) and \( L^0 \) belong to the same isometry class if, for every basis \( A \) of \( L \), there is a basis \( A^0 \) of \( L^0 \) and an orthogonal transformation \( O \in O_d(\mathbb{R}) \) such that \( A^0 = OA \).

The Minkowski sum \( L + B^d = \{ v + x : v \in L, x \in B^d \} \), with \( \mathbb{R} > 0 \), is a lattice packing if the translates of \( B^d \) have mutually disjoint interiors and a lattice covering if \( E^d = L + B^d \). The packing radius \( (L) \) of a lattice \( L \) is given by

\[
(L) = \max \{ d : L + B^d \text{ is a lattice packing} \};
\]

and the covering radius \( (L) \) by

\[
(L) = \min \{ d : L + B^d \text{ is a lattice covering} \};
\]

The above values are attained: The packing radius is equal to half the length of a shortest non-zero vector of \( L \) and the covering radius is equal to the maximum distance of points in \( E^d \) to a closest lattice vector. The packing radius is the inradius of the Dirichlet-Voronoi polytope of \( L \)

\[
DV(L) = \{ x \in E^d : kx \in L, k \in \mathbb{Z} \};
\]

and the covering radius is its circumradius. Both functionals are homogeneous, that is, for \( \lambda \in \mathbb{R} \) we have

\[
(L) = \lambda (L) \quad \text{and} \quad (L) = \lambda (L);
\]

Thus, the covering density

\[
\frac{(L)}{\det(L)}
\]

is invariant with respect to scaling of \( L \). The same is true for the packing-covering constant

\[
\frac{(L)}{(L)}
\]

All these functionals are invariants of the isometry classes.

In this paper we study the following two problems:

**Problem 2.1. (Lattice covering problem)**

For a given \( d \in \mathbb{N} \), determine \( d = m \in L \) (L), where \( E^d \) runs over all \( d \)-dimensional lattices.

**Problem 2.2. (Lattice packing-covering problem)**

For a given \( d \in \mathbb{N} \), determine \( d = m \in L \) (L), where \( E^d \) runs over all \( d \)-dimensional lattices.
We describe history and results of both problems in Section 3 and Section 4. There we assume that the reader is familiar with certain important lattices which are described in [CS88, Ch. 4]. Historically and for computational reasons, the problems were studied by using the intimate relation between lattices and positive definite quadratic forms (PQFs).

Let us describe this relation: To a \( d \)-dimensional lattice \( L = \mathbb{Z}^d \) with basis \( A \) we associate a \( d \)-dimensional PQF

\[
Q[A] = x^T A^T A x = x^T G x;
\]

where the Gram matrix \( G = A^T A \) is symmetric and positive definite. We abuse notation and identify quadratic forms with symmetric matrices by saying \( Q = G \) and \( Q[A] = x^T Q x \). The set of quadratic forms is a \( \frac{d(d+1)}{2} \)-dimensional real vector space \( S^d \), in which the set of PQFs forms an open, convex cone \( S^d_0 \). Its closure is the convex cone of all positive semidefinite quadratic forms \( S^d \), which is pointed at 0.

Note that \( Q \) depends on the chosen basis \( A \) of \( L \). Two arbitrary bases \( A \) and \( B \) of \( L \) are transformed into each other by a unimodular transformation, that is, there exists an \( U \in GL_d(\mathbb{Z}) \) such that \( A = B U \). Thus, \( GL_d(\mathbb{Z}) \) acts on \( S^d_0 \) by \( Q \mapsto U^T Q U \). Two PQFs lying in the same orbit under this action are called arithmetically equivalent. This definition naturally extends to positive semidefinite quadratic forms.

Thus every lattice uniquely determines an arithmetical equivalence class of PQFs. On the other hand, every PQF \( Q \) admits a Cholesky decomposition \( Q = A^T A \), where the upper triangular matrix \( A \) is uniquely determined up to an orthogonal transformation \( O \in O_d(\mathbb{R}) \). Altogether, we have a bijection between isometry classes of lattices \( O_d(\mathbb{R}) \times GL_d(\mathbb{R}) = GL_d(\mathbb{Z}) \) and arithmetical equivalence classes of PQFs \( S^d_0 = GL_d(\mathbb{Z}) \).

As a consequence, the lattice covering and the lattice packing-covering problem translate into problems for PQFs: The determinant (or discriminant) of a PQF \( Q \) is defined by \( \det(Q) \). The homogeneous minimum \( (Q) \) and the inhomogeneous minimum \( (Q) \) are given by

\[
(Q) = \min_{v \in \mathbb{Z}^d \cap 0} Q[v] \quad \text{and} \quad (Q) = \max_{x \in \mathbb{Z}^d \cap 0} Q[x - v].
\]

A corresponding lattice \( L \) satisfies \( \det(L) = \det(Q) \), \( (L) = \det(Q) \), \( (L) = \det(Q) \). Therefore our goal is to minimize

\[
(Q) = \min_{Q \in S^d_0} \frac{s}{\det(Q)} d^d \quad \text{and} \quad (Q) = \min_{Q \in S^d_0} \frac{s}{(Q)} 2^d.
\]

among all PQFs \( Q \in S^d_0 \).

Since \( (Q) \) and \( (Q) \) are invariant with respect to the action of \( GL_d(\mathbb{Z}) \) on \( S^d_0 \), we only need to consider one PQF in each arithmetical equivalence class. Finding a fundamental domain in \( S^d_0 \) is one of the most basic and classical problems in the geometry of numbers. Such a reduction theory for PQFs, especially suitable for Problem 2.4 and Problem 2.2, is due to Voronoi. We describe it in detail in Section 5.

### 3 The Lattice Covering Problem

Kershner, in 1939, was the first to consider the lattice covering problem. In [Ker39] he showed that the hexagonal lattice (see Figure 1) gives the most economical sphere covering in the plane even without the restriction of being a lattice covering.
Since then the lattice covering problem has been solved up to dimension 5 (see Table 1). In all these cases the lattice $A_d$, whose covering density equals
\[
(A_d) = \frac{s}{\frac{d(d+2)}{12(d+1)} (d+1)^d};
\]
provides the optimal lattice covering. Gamekii [Gam62], [Gam63], and Bleicher [Ble62] were the first to compute the covering density of $A_d$ for general $d$. They also showed that it is locally optimal with respect to covering density in every dimension.

The optimality of the body centered cubic lattice $A_3$ whose Dirichlet-Voronoi polytope is a regular truncated octahedron (the Dirichlet-Voronoi polytope of $A_d$ is a regular permutahedron) was first proven by Bambah [Bam54b]. Later, Barnes substantially simplified Bambah’s proof in [Bar56] and strengthened the result by showing that in dimensions 2 and 3 the lattice $A_d$ is the unique locally optimal lattice covering. He used Voronoi’s reduction theory and anticipated that this is the right setup for solving the lattice covering problem in dimensions larger than three. Our algorithm in Section 8.1 confirms his anticipation. A third proof, which is mainly elementary and unlike the previous two does not use any reduction theory of PQFs, was given by Few [Few56]. At the moment no attempt is known to the authors to show that the optimal three-dimensional lattice covering also gives an optimal sphere covering without lattice restriction.

In [Bam54a] Bambah conjectured that the lattice $A_4$ gives the least dense four-dimensional lattice covering. In [DR63] Delone and Ryshkov proved Bambah’s conjecture. In [Bar65], [Bar66] Baranovskii gave an alternative proof of this fact. He determined all locally optimal lattice coverings in dimension 4. Dickson [Dic67] gave another alternative proof of this fact.

In a series of papers [Rys73], [BR73], [BR75], [RB75] Ryshkov and Baranovskii solved the lattice covering problem in dimension 5. They prepared a 140-page long monograph [RB78] based on their investigations.

| $d$ | lattice covering | covering density |
|-----|------------------|------------------|
| 1   | $Z^1$            | 1                |
| 2   | $A_2$            | 1.209199         |
| 3   | $A_3$            | 1.463505         |
| 4   | $A_4$            | 1.765529         |
| 5   | $A_5$            | 2.124286         |

Table 1. Optimal lattice coverings.
In [Rys67] Ryshkov raised the question of finding the lowest dimension \( d \) for which there is a better lattice covering than the one given by \( A_d \). In the same paper he showed that \( A_d \) is not the most efficient lattice covering for all even \( d \geq 114 \) and for all odd \( d \geq 201 \). One of our main results in this paper is the answer to Ryshkov’s question (see Theorem 11.3): Dimension \( d = 6 \) is the lowest dimension for which there is a better lattice covering than the one given by \( A_d \). The proof is based on a computer search. In Section 8.1 we will give an algorithm which finds all locally optimal lattice coverings in a given dimension. Using this algorithm we are able to verify all of the known results about optimal lattice coverings up to dimension 5. Unfortunately, due to a combinatorial explosion, the algorithm cannot be applied practically in dimension 6 or greater. Nevertheless, we are able to find good lattice coverings in dimension 6, 7, and 8 by applying several heuristics. We will give more details in Section 11.

| \( d \) | lattice | covering density |
|-------|--------|------------------|
| 6     | \( L_6^3 \) | 2.464801         |
| 7     | \( L_7^7 \) | 2.900024         |
| 8     | \( L_8^8 \) | 3.142202         |
| 9     | \( A_9^9 \) | 4.340185         |
| 10    | \( A_{10}^{10} \) | 5.251713         |
| 11    | \( A_{11}^{11} \) | 5.598338         |
| 12    | \( A_{12}^{12} \) | 7.510113         |
| 13    | \( A_{13}^{13} \) | 7.864060         |
| 14    | \( A_{14}^{14} \) | 9.006610         |

Table 2. Least dense known (lattice) coverings up to dimension 24.

What else is known? In Table 2 we list all the least dense known lattice coverings in dimensions 6 to 24. At the same time this list gives the least dense known sphere coverings. There is no covering of equal spheres known which is less dense than the best known lattice covering. This table is an update of Table 2 in [CS88] and we provide an up-to-date table on our web page [SV05]. We conclude this section by briefly describing the origins of these updates.

The Leech lattice \( \Lambda_{24} \) yields the best known lattice covering in dimension 24. The covering density of the Leech lattice was computed by Conway, Parker and Sloane ([CS88] Ch. 23). It is not too brave to conjecture that the Leech lattice gives the optimal 24-dimensional sphere covering. In [SV04] we took a first step towards proving this conjecture by showing that the Leech lattice gives a locally optimal lattice covering. Using the Leech lattice Bambah and Sloane constructed in [BS82] a series of lattices in dimensions \( d \geq 24 \) which give a thinner lattice covering than \( A_d \). It seems that as a “corollary” of the existence of the Leech lattice the duals of the laminated lattices \( D_n \) and \( E_n \) give good lattice coverings. Their covering densities were estimated by Smith [Smi88], but we do not know the exact values of \( \langle 22 \rangle \) and \( \langle 23 \rangle \). For the definitions of the root lattices \( A_n \), \( D_n \), \( E_n \), and the laminated lattices \( n \), we refer to [CS88], Ch. 4 and Ch. 6.
In [Cox51] Coxeter gave a list of locally optimal lattice packings (extreme lattices) which are related to Lie groups. One of them is the infinite series of locally densest packing lattices \( A_r^d \) where \( d \geq 2 \) and \( r > 1 \) divides \( d+1 \). The lattice \( A_{2r}^d \) is the unique sublattice of \( A_d^d \) containing \( A_d^d \) to index \( r \). In [Bar94] Baranovskii determined the covering density of the lattice covering given by \( A_{2r}^d \), which is slightly better than the one given by \( A_d^d \). Recently, Anzin extended Baranovskii’s work. In [Anz02] he computed the covering densities of \( A_{11}^4 \) and \( A_{13}^7 \), and in a private communication he reported on computing the covering densities of \( A_{14}^5 \) and \( A_{15}^8 \). They all give less dense lattice coverings than those provided by the corresponding \( A_d^d \). We do not know whether these lattice coverings are locally optimal.

To answer Ryshkov’s question exhaustively it will be necessary to further investigate lattice coverings in the dimensions \( d = 10; 12; 16; 17; \ldots; 21 \). We hope that the methods we present in this paper will be useful for this project.

### 4 The Lattice Packing-Covering Problem

The lattice packing-covering problem has been studied in different contexts and there are several different names and interpretations of the lattice packing-covering constant \( d_d \). Lagarias and Pleasants [LP02] referred to it as the “Delone packing-covering constant”. Ryshkov [Rys74] studied the equivalent problem of minimizing the density of \((r; R)\)-systems. An \((r; R)\)-system is a discrete point set \( X \subseteq \mathbb{R}^d \) where (1) the distance between any two points of \( X \) is at least \( r \) and (2) the distance from any point in \( \mathbb{R}^d \) to a point in \( X \) is at most \( R \). If \( X \) is a lattice, then \( r = \sqrt{\chi X} = 2 \) and \( R = \sqrt[3]{\chi X} \).

![Figure 2. A close sphere packing given by the hexagonal lattice.](image)

Geometrically we may think of solving the lattice packing-covering problem as of maximizing the minimum distance between lattice points in a lattice covering with unit spheres. Alternatively, we may think of it as minimizing the radius of a largest sphere that could additionally be packed into a lattice packing of unit spheres (see Figure 2). This minimal gap-radius is equal to \( d_d = 1 \). Therefore the problem raised by L. Fejes Tóth [Tó76] of finding “close packings” attaining this gap-radius is another formulation of the packing-covering problem.

The last interpretation shows that \( d_d = 2 \) would imply that in any \( d \)-dimensional lattice packing with spheres of unit radius there is still space for spheres of radius 1. In particular, this would prove that densest sphere packings in dimension \( d \) are non-lattice packings. This phenomenon is likely to be true for large dimensions, but it has not been verified for any \( d \) so far.

**Problem 4.1.** Does there exist a \( d \) such that \( d_d = 2 \)?
Note that this problem is particularly challenging in view of the asymptotic bound \( d + o(1) \) due to Butler [But72].

As for the lattice covering problem, the lattice packing-covering problem has been solved up to dimension 5 (see Table 3). Ryshkov [Rys74] solved the general 2-dimensional case. The 3-dimensional case was settled by Böröczky [Bör86], even without the restriction to lattices. The 4- and 5-dimensional cases were solved by Horváth [Hor82], [Hor86]. Note that the lattices \( \mathbb{H} \) and \( \mathbb{H} \) (see Section 1) discovered by Horváth are neither best covering, nor best packing lattices. As in the case of lattice coverings, the results were attained by using Voronoi’s reduction theory.

Our computations, described in Section 11 verify all of the known results in dimension 5. As for the covering problem, none of the values \( d \) has been determined in a dimension \( d > 6 \) so far. In Section 11 we report on a new best known packing-covering lattice for \( d = 6 \). We thereby show in particular that \( 6 < 5 \), recently suspected by Lagarias and Pleasants [LP02], Sec. 7. Note that this was already observed by Zong [Zon02] (Remark 3), who showed that \( (E_6^6) = \sqrt{2} < 5 \).

We were not able yet to find any new best known lattices in dimensions \( d > 7 \). The lattice \( E_7 \) gives the best known lattice in dimension 7. Nevertheless, because of their symmetry and the known bounds on \( d \), Zong [Zon02] (Conjecture 3.1) made the following conjectures: \( E_8 \) and Leech lattice \( 24 \) are optimal in their dimensions. In [SV04] we showed that the Leech lattice gives a locally optimal lattice packing-covering constant. It is an open question whether or not the root lattice \( E_8 \) gives a locally optimal lattice packing-covering constant as well. The corresponding values of the lattice packing-covering constant are shown in Table 4. In dimension 7 and between dimensions 8 and 24 we do not yet know enough to state any serious conjectures. The exact value for the smallest known lattice packing-covering constant in dimension 6 is \( 2^7 \sqrt{798} \) (see Section 1).

| \( d \) | lattice | lattice packing-covering constant |
|-------|--------|----------------------------------|
| 6     | \( \mathbb{L}^6 \) | \( 2 \sqrt{798} \) 56 \( 1\times411081 \) |
| 7     | \( \mathbb{E}_7 \) | \( 2^7 \sqrt{798} \) 56 \( 1\times41213 \) |
| 8     | \( \mathbb{E}_8 \) | \( 2^7 \sqrt{798} \) 56 \( 1\times41213 \) |
| 24    | \( 24 \) | \( 2^7 \sqrt{798} \) 56 \( 1\times41213 \) |

Table 4. Lattice packing-covering records.

5 Voronoi’s Reduction Theory

The general task of a reduction theory for PQFs is to give a fundamental domain for \( \mathbb{S}^d_0 = \mathbb{G}_{\mathbb{L}_d} (\mathbb{Z}) \). This is a subset which behaves like \( \mathbb{S}^d_0 = \mathbb{G}_{\mathbb{L}_d} (\mathbb{Z}) \) up to boundary identifications. There are many different reduction theories, connected with names like Lagrange, Gauß, Hermite, Korkine, Zolotareff, Minkowski, Voronoi, and others (see [SO85]). In this section we describe the reduction theory developed by Voronoi in [Vor90]. It is based on Delone triangulations.
5.1 Secondary Cones of Delone Triangulations

Let \( Q \subseteq S_d^d \) be a PQF. A polytope \( L = \text{conv} v_1; \ldots; v_n \) with \( v_1; \ldots; v_n \) in \( Z^d \), is called a Delone polytope of \( Q \) if there exists a \( c \subseteq R^d \) and a real number \( r \subseteq R \) with \( Q [v_i \ c] = r^2 \) for all \( i = 1; \ldots; n \), and for all other lattice points \( v \subseteq Z^d \), \( v \neq v_i \), we have strict inequality \( Q [v \ c] > r^2 \). The set of all Delone polytopes

\[ D \subseteq (Q) = fL : L \text{ is a Delone polytope of } Q \]

is called the Delone subdivision (or \( L \)-partition) of \( Q \). A Delone triangulation is a Delone subdivision that consists of simplices only. For historical reasons we use the letter \( L \) to denote Delone polytopes (see [Vor08] and [Del38]).

The Delone subdivision of a PQF is a periodic polytopal subdivision of \( R^d \). We say that two Delone polytopes \( L \) and \( L^0 \) are equivalent if there is a \( v \subseteq Z^d \) with \( L^0 = L + v \). Given a Delone subdivision \( D \) of \( R^d \), the set of PQFs with Delone subdivision \( D \) forms the secondary cone

\[ \{D) = fQ : 2S_+^d : D \subseteq (Q) = D \}

In the literature it is often referred to as the \( L \)-type domain of \( Q \).

5.5 We prefer the term “secondary cone” because of the close connection of Voronoi’s reduction theory to the theory of secondary polytopes which we will point out in Section 5.5.

Let \( Q \) be a PQF whose Delone subdivision is a triangulation of \( R^d \). In the following we will describe the secondary cone of \( D \subseteq (Q) \). For this, let \( L = \text{conv} v_1; \ldots; v_{d+1} \) and \( L^0 = \text{conv} v_2; \ldots; v_{d+2} \) be two \( d \)-dimensional Delone simplices of \( Q \), sharing the common facet \( F = \text{conv} v_1; \ldots; v_{d+1} \). Let \( 1; \ldots; d+2 \) be real numbers with \( 1 = 1, F_{d+2} v_1 = 0 \) and \( F_{d+2} v_1 = 0 \) (hence \( d+2 > 0 \)). The regulator of the pair of adjacent simplices \( (L; L^0) \) is the linear form \( \frac{1}{2} \text{reg} (Q) = F_{d+2} v_1 \) \( Q^0 2 S^d \).

In particular, note that the regulator solely depends on the points \( v_1; \ldots; v_{d+2}, \) that \( \frac{1}{2} \text{reg} (Q) > 0 \), and that \( \frac{1}{2} \text{reg} (Q) = \frac{1}{2} \text{reg} (Q) \) for all \( v \subseteq Z^d \). One can describe \((D \subseteq (Q))\) by linear inequalities coming from the (finitely many) regulators of \( D \subseteq (Q) \):

**Proposition 5.1.** ([Vor08], x77) Let \( Q \) be a PQF whose Delone subdivision is a triangulation. The secondary cone of the Delone triangulation \( D \subseteq (Q) \) is the full-dimensional open polyhedral cone

\[ \{D \subseteq (Q) = fQ : 2S_+^d : \frac{1}{2} \text{reg} (Q) > 0, \text{for all pairs } (L; L^0) \text{ of adjacent simplices of } D \subseteq (Q) \} \]

Note on the one side that \((D \subseteq (Q))\) is contained in \( S_+^d \) by definition and on the other side that the linear inequalities given by the regulators imply that a quadratic form which satisfies them is positive definite.

**Example 5.2.** As a first example and because of its importance for the lattice problems introduced in Section 2 we describe the Delone subdivision of Voronoi’s principal form of the first type \( Q [x] = d x_1^2 x_2 \ldots x_d \), which is associated to the lattice \( A_d \), in greater detail. The Delone subdivision of \( Q \) is a triangulation and can be described as follows: Let \( e_1; \ldots; e_d \) be the standard basis vectors of \( Z^d \), and set \( e_{d+1} = e_1 \ldots e_d \). For a permutation \( 2S_{d+1} \) we define the \( d \)-dimensional simplex \( L \) by

\[ L = \text{conv} e_{d+1}; e_1; \ldots; e_d \]

The set of simplices \( fL + v : v \subseteq Z^d \) \( 2S_{d+1} \) defines a triangulation of \( R^d \) which we from now on denote by \( D_1 \). The full-dimensional cells containing the origin are \( L \), \( 2S_{d+1} \). Two simplices \( L \) and \( L^0 \) have a facet in common if and only if \( \text{and } 0 \) differ by a single transposition of two adjacent positions. The automorphism group of \( D_1 \) is isomorphic to the permutation group \( S_{d+1} \). The star of the origin is illustrated in Figure 3. This consists of all Delone polytopes containing the origin.
The secondary cone of $D_1$ is (see [Vor08], x102–104)

$$\mathcal{D}_1 = fQ_2 S^d : q_{ij} < 0 \text{ for } i \neq j \text{ and } f_{\psi q_{ij}} > 0 \text{ for } j = 1, \ldots, d$$

Its topological closure $\overline{\mathcal{D}_1}$ is called Voronoi’s principal domain of the first type.

It was shown by Voronoi ([Vor08], x97) that the topological closures of the secondary cones gives a facet-to-facet tessellation of $S^d_0$. By a theorem of Gruber and Ryshkov [GR89] we even have a face-to-face tessellation because “facet-to-facet implies face-to-face”. This means that a face sharing relative interior points with another face of its dimension coincides with this face, whenever this property holds for the facets (faces of co-dimension 1).

5.2 Bistellar Operations

Now, given a secondary cone, how do we find its neighbors, that is, those secondary cones sharing a facet with the given one?

An answer can be given by taking a closer look at the so-called repartitioning polytopes (introduced by Ryshkov and Baranovskii in [RB78]), which are “hidden” in the definition of the regulators. Repartitioning polytopes are $d$-dimensional Delone polytopes having a representation as the convex hull of two Delone simplices sharing a common facet. Thus, repartitioning polytopes have $d + 2$ vertices.

Generally, $d$-dimensional polytopes with $d + 2$ vertices have the special property that there are exactly two different ways to triangulate them: Let $V$ be a set of $d + 2$ points which affinely spans $\mathbb{R}^d$. Let $v_2 \in V$, $v = 0$, be an affine relation between these points. There exist exactly two triangulations of $\text{conv } V : T_+ (V; )$ with $d$-simplices $\text{conv } (V n f v g)$, $v > 0$, and $T (V; )$ with $d$-simplices $\text{conv } (V n f v g)$, $v < 0$ (see for example [GKZ94], Ch. 7, Prop. 1.2).

Let $D$ be a Delone triangulation of $\mathbb{R}^d$ and let $F$ be a $(d - 1)$-dimensional cell of $D$. Then, $F$ is contained in two simplices $L$ and $L^0$ of $D$. By $V$ we denote the set of vertices of $L$ and $L^0$, $V = \text{vert } L \cup \text{vert } L^0$. By we denote an affine relation between the points in $V$. The $(d - 1)$-dimensional cell $F$ is called a flippable facet of the triangulation $D$ if one of the triangulations $T_+ (V; )$ or $T (V; )$ is a subcomplex of $D$. If $F$ is a flippable facet of $D$ and we replace the subcomplex $T_+ (V; )$ by $T (V; )$ [respectively $T (V; )$ by $T_+ (V; )$], then we get a new triangulation. This replacement is called bistellar operation or flip.

Notice that non-flippable facets do exist and that performing a bistellar operation in a Delone triangulation does not necessarily produce a Delone triangulation. Both phenomena occur starting from dimension 4.
Nevertheless, the facets of \( D \) correspond exactly to those bistellar operations of \( D \) which yield new Delone triangulations. A \((d-1)\)-dimensional cell \( L \setminus L^0 \) of \( D \) is a flippable facet whenever the corresponding regulator \( \%_{\alpha,\mu,\nu} \) gives a facet-defining hyperplane of \( D \) (see [Vor08], x87–88). This is clear since the repartitioning polytope \( \text{conv}(L \setminus L^0) \) is a Delone polytope of the PQFs lying in the relative interior of the facet given by \( \%_{\alpha,\mu,\nu} \).

Let \( F \) be a facet of \( D \). We describe how the Delone triangulation \( D \) changes if we vary a PQF continuously: We start from the interior of \( D \), then we move towards a relative interior point of \( F \) and finally we go infinitesimally further, leaving \( D \). In every repartitioning polytope \( V = \text{conv}(L \setminus L^0) \) where \( L \setminus L^0 \) is a pair of adjacent simplices whose regulator defines \( F \), i.e. the linear span of \( F \) satisfies \( \text{lin}(F) = \{Q \in S^d : \%_{\alpha,\mu,\nu}(Q) = 0\} \), we perform a bistellar operation. This gives a new triangulation \( D^0 \), which is again a Delone triangulation. The two secondary cones \( D \) and \( D^0 \) have the complete facet \( F \) in common. We say that \( D \) and \( D^0 \) are bistellar neighbors. In [Vor08] x91–96, Voronoi computes the secondary cone of \( D^0 \) explicitly and shows that \( D^0 \) has dimension \( \frac{d(d+1)}{2} \).

### 5.3 Main Theorem of Voronoi’s Reduction Theory

By constructing bistellar neighbors we could produce infinitely many Delone triangulations starting from the Delone triangulation \( D \) of Voronoi’s principal form of the first type (a part of the infinite flip graph of two-dimensional Delone triangulations is given in Figure 4). Many of these will not be essentially new, because the group \( \text{GL}_d(\mathbb{Z}) \) is acting on the set of Delone subdivisions by \( A \cdot D \mapsto A D \) and it is acting on the set of secondary cones by \( A \cdot \text{cone}(D) \mapsto \text{cone}(A D) \text{ for } A \in \text{GL}_d(\mathbb{Z}) \). We are only interested in the orbits of these group actions and there are only finitely many, as shown by Voronoi [Vor08] x98 (see also Deza, Grishukhin and Laurent in [DL97], Chapter 13.3). Altogether we get:

**Theorem 5.3.** (Main Theorem of Voronoi’s Reduction Theory)

The secondary cone of a Delone triangulation is a full-dimensional, open polyhedral cone in \( S^d \). The topological closures of secondary cones of Delone triangulations give a face-to-face tiling of \( S^d \). Two secondary cones share a facet if and only if they are bistellar neighbors. The group \( \text{GL}_d(\mathbb{Z}) \) acts on the tiling, and under this group action there are only finitely many inequivalent secondary cones.

The main theorem translates into Algorithm 1 which enumerates all inequivalent Delone triangulations in a given dimension. We developed the program \( \text{scc (secondary cone cruiser)} \) which is an implementation of Algorithm 1. The interested reader can download \( \text{scc} \) from our web page [SV05]. Using our implementation we succeeded in reproducing the classification of all inequivalent Delone triangulations up to dimension 5. Table 5 shows the numbers.
Input: Dimension $d$.
Output: Set $R$ of all inequivalent $d$-dimensional Delone triangulations.

$$T \ni D_1 g, \text{ where } D_1 \text{ is the Delone triangulation described in Example 5.2}.$$

while there is a $D \rightarrow T$ do
  $T \ni D_1 g, R \ni [fD_1g.$
  compute the regulators of $D$.
  compute the facets $F_1 ; \ldots ; F_n$ of $D$.
  for $i = 1 ; \ldots ; n$ do
    compute the bistellar neighbor $D_i$ of $D$ which is defined by $F_i$.
    if $D_i$ is not equivalent to a Delone triangulation in $R \ni [fD_1; \ldots ; D_1g$ then
      $T \ni [fD_1g.$
    end if
  end for
end while

Algorithm 1. Enumeration of all inequivalent Delone triangulations.

We are not the first to compute this classification. Voronoi performed the classification of all inequivalent Delone triangulation up to dimension 4 in his memoir [Vor08]. In [BR73] and [RB78] Ryshkov and Baranovskii reported on 221 inequivalent Delone triangulation in dimension 5. However, they missed one type which was found by Engel [Eng98]. Grishukhin and Engel [EG02] undertook the non-trivial task of identifying the Delone triangulation missing in the list of Ryshkov and Baranovskii. There they also report on several errors in both lists. Our computations confirm that the number of Delone triangulations in dimension 5 is 222. Beginning with dimension 6 the number of inequivalent Delone triangulations starts to explode. We found more than 250;000 inequivalent triangulations before our implementation stopped because of memory reasons. We do not know how many inequivalent triangulations we have to expect in dimension 6 but we are quite certain that we only saw a small fraction of them. No non-trivial bounds on the number of inequivalent Delone triangulations for general dimension $d$ are known.

| Dimension | 1 | 2 | 3 | 4 | 5 |
|-----------|---|---|---|---|---|
| # Delone triangulations | 1 | 1 | 1 | 3 | 222 |

Table 5. Numbers of inequivalent Delone triangulations.

5.4 Degeneracy

Until now we have only dealt with Delone triangulations of positive definite quadratic forms. Let us look at possible degenerations — Delone subdivisions of positive semidefinite quadratic forms — and find out how they fit into the theory developed so far.

Let $Q$ be a positive semidefinite quadratic form which is arithmetically equivalent to $0 \ 0 \ 0 \ 0 \ 0$ where $Q^0$ is positive definite. Then, we can use the definition of Delone subdivision almost literally; we only have to replace “polytope” by “polyhedron” (a polyhedron is the intersection of finitely many half spaces; a polytope is a bounded polyhedron).

Delone subdivisions are limiting cases of triangulations. Their secondary cones occur on the boundaries of full-dimensional secondary cones of Delone triangulations. Let $D$ and $D^0$ be two Delone subdivisions. We say $D$ is a refinement of $D^0$ if every Delone polytope of $D$ is a subset of some Delone polytope of $D^0$. The following proposition, which seems to be folklore, shows that the relation between refinements, secondary
cones and sums of positive semidefinite quadratic forms is very natural. One can find a proof for example in [Val03] (Prop. 2.6.1).

**Proposition 5.4.** Let $D$ be a Delone triangulation.

1. A positive semidefinite quadratic form $Q$ lies in \( (D) \) if and only if $D$ is a refinement of $D \oplus (Q)$.

2. If two positive semidefinite quadratic forms $Q$ and $Q^0$ both lie in \( (D) \), then $D \oplus (Q + Q^0)$ is a common refinement of $D \oplus (Q)$ and $D \oplus (Q^0)$.

Therefore, the classification of all inequivalent Delone subdivisions is equivalent to the classification of all inequivalent secondary cones. This has been done up to dimension 5. The 1- and 2-dimensional cases are trivial; the 3-dimensional case goes back to Federov, who classified all polytopes which tile 3-dimensional space by translates in 1885. Delone [Del29] (later corrected by Stogrin [Sto73]) found 51 of the 52 Delone subdivisions in dimension 4. Recently, Engel [Eng00] reported that there are 179;372 inequivalent five-dimensional Delone subdivisions. It is possible to verify his result by enumerating the faces of the 222 secondary cones of Delone triangulations in dimension 5 up to equivalence. Since we do not need Engel’s result for our application we did not verify it. Again, the number in dimension 6 is not known and will be much larger. Table 6 summarizes this discussion.

| Dimension | 1 | 2 | 3 | 4 | 5 |
|-----------|---|---|---|---|---|
| # Delone subdivisions | 1 | 2 | 5 | 52 | 179;372 |

Table 6. Numbers of inequivalent Delone subdivisions.

### 5.5 Generalized Secondary Polytopes

Triangulations of discrete point sets have attracted many researchers in recent years. They have many applications, for example in computational geometry, optimization, algebraic geometry, topology, etc. One main tool to understand the structural behavior of triangulations of finite point sets is the theory of secondary polytopes invented by Gel’fand, Kapranov and Zelevinsky ([GKZ94], Ch. 7).

Let $A = a_1, \ldots, a_n \in \mathbb{R}^d$ be a finite set of points. Let $w : A \to \mathbb{R}$ be a map that assigns to every point in $A$ a weight. The set of weight maps forms a vector space over $\mathbb{R}$ which we denote by $\mathbb{R}^A$. A lifting map $l : A \to \mathbb{R}^d \to \mathbb{R}$, $l(a_j) = (a_j, w(a_j))$ is defined by $w$ which lifts each point $a_j \in A$ by its weight $w(a_j)$. A subdivision of the convex polytope $\text{conv} A$ is induced by $l$. We take the convex hull of the lifted points $\text{conv} l(A)$ and project its lower faces as seen from $(0; 1)$ back down onto $\mathbb{R}^d$. A subdivision that can be obtained in this manner is called a regular subdivision. Delone subdivisions (or more precisely Delone subdivisions of finitely many points) are regular subdivisions since the underlying positive semidefinite quadratic form is the weight function. This view on Delone subdivisions was introduced by Brown [Bro79] and by Edelsbrunner and Seidel [ES86].

Let $T$ be a regular triangulation of $\text{conv} A$. We may ask what are the weight functions which define $T$. What is the secondary cone of $T$ in the parameter space $\mathbb{R}^A$? As in Voronoi’s reduction theory it turns out that the secondary cone of $T$ is a full-dimensional open polyhedral cone. The topological closures of the secondary cones of all regular triangulations tile the space $\mathbb{R}^A$ face-to-face. The tiling is called secondary fan of $A$. If two secondary cones have a facet in common, then the corresponding regular triangulations differ by a bistellar operation in exactly one “repartitioning polytope” (in this context it is a polytope with $d + 2$ vertices without the condition of being a Delone polytope) that is defined by the facet. The faces in the secondary fan $A$ are in a one-to-one correspondence to regular subdivisions in essentially the same way we discussed in Section 5.4 for Delone subdivisions.
So far we have seen that the theory of regular subdivisions of finite point sets and the theory of Delone subdivisions of the lattice $\mathbb{Z}^d$ can be developed analogously, but there are also differences: The parameter space for regular subdivisions is the vector space $\mathbb{R}^d$, while for Delone subdivisions it is the pointed cone $\mathbb{Z}^d_0$. Groups play an important role for Delone subdivisions. The group $\mathbb{Z}^d$ is acting on Delone subdivisions by translations. On the set of secondary cones the group $GL_d(\mathbb{Z})$ is acting.

If we order all regular subdivisions of $\overline{conv A}$ by refinement we get a poset. This poset has a very nice combinatorial structure as proved by Gel’fand, Kapranov and Zelevinsky: There exists a polytope — the secondary polytope $(A)$ of $A$ — whose normal fan equals the secondary fan of $A$. So the refinement poset is anti-isomorphic to the face lattice of the secondary polytope. Regular triangulations are in one-to-one correspondence to the vertices, two regular triangulations differ by a bistellar operation if and only if their vertices are connected by an edge, etc.

Recently, a similar combinatorial structure lurking behind the refinement poset of $\mathbb{Z}^d$-periodic subdivisions (this poset contains the poset of Delone subdivisions) has been described by Alexeev [Ale02], Sec. 5.11 and 5.12. He gives an unbalanced and a balanced version of these generalized secondary polytopes, where the latter one is invariant with respect to the group action of $GL_d(\mathbb{Z})$.

6 Convex Optimization with LMI Constraints

In this section we introduce determinant maximization problems, which are convex programming problems with linear matrix inequality constraints. In a sense they are equivalent to the better known semidefinite programming problems. For both classes efficient algorithms and implementations are available. In Section 8 we will see how Problem 2.1 and Problem 2.2 can naturally be formulated as a finite number of determinant maximization problems.

Following Vandenberghe, Boyd, and Wu [VBW98] we say that a determinant maximization problem is an optimization problem of the form

\begin{align}
\text{minimize} & \quad c^T x \quad \log \det G(x) \\
\text{subject to} & \quad G(x) \text{ is a positive definite matrix;} \\
& \quad F(x) \text{ is a positive semidefinite matrix:} \tag{1}
\end{align}

The optimization vector is $x \in \mathbb{R}^d$, the objective vector is $c \in \mathbb{R}^d$, and $G : \mathbb{R}^d \to \mathbb{R}^m$ and $F : \mathbb{R}^d \to \mathbb{R}^n$ are affine maps:

\[
G(x) = G_0 + x_1 G_1 + \cdots + x_d G_d; \\
F(x) = F_0 + x_1 F_1 + \cdots + x_d F_d;
\]

where $G_i : \mathbb{R}^m$ and $F_i : \mathbb{R}^n$, for $i = 0; \ldots; d$, are symmetric matrices. In the sequel we will write $G(x) = 0$ and $F(x) = 0$ for the linear matrix inequalities defining the constraints of the determinant maximization problem. As a special case, our formulation reduces to a semidefinite programming problem whenever $G(x)$ is the identity matrix for all $x \in \mathbb{R}^d$.

Currently there exist two different types of algorithms — ellipsoid and interior-point methods — which efficiently solve semidefinite programming problems. They can approximate the solution of a semidefinite programming problem within any specified accuracy and run in polynomial time if the instances are “well-behaved”. For more information on the exciting topic of semidefinite programming the interested reader is referred to the vast amount of literature which to a great extend is available on the World Wide Web. A good starting point is the web page\(^1\) of Christoph Helmberg.

\[^1\]http://www-user.tu-chemnitz.de/~helmberg/semidef.html
Nesterov and Nemirovskii [NN94] developed a framework for the design of efficient interior-point algorithms for general and specific classes of convex programming problems. There (§6.4.3), they also showed that the determinant maximization problem can be transformed into a semidefinite programming problem by a transformation which can be computed in polynomial time. Nevertheless it is faster to solve the determinant maximization problem directly. Vandenberghe, Boyd, Wu [VBW98] and independently Toh [Toh99] gave interior-point algorithms for the determinant maximization problem. Both algorithms fit into the general framework of Nesterov and Nemirovskii. For our implementation we use the software package MAXDET² of Wu, Vandenberghe, and Boyd as a subroutine.

One nice feature of determinant maximization problems is that there is a duality theory similar to the one of linear programming, which allows one to compute certificates for a range in which the optimum is attained, the so-called duality gap. The dual problem of problem (1) is (see [VBW98], Sec. 3)

\[
\begin{align*}
\text{maximize} & \quad \log \det W \quad \text{trace}(G_0 W) \quad \text{trace}(F_0 Z) + m \\
\text{subject to} & \quad \text{trace}(G_i W) + \text{trace}(F_i Z) = c_i \text{ for } i = 1; \ldots; d, \quad W \geq 0, \quad Z \geq 0.
\end{align*}
\]

(2)

Here, \( W \in \mathbb{R}^{m \times m} \) and \( Z \in \mathbb{R}^{n \times n} \) are symmetric matrices of the same size as the \( G_i \) and \( F_i \) respectively.

The knowledge of a vector \( x \) with \( G(x) = 0 \) and \( F(x) = 0 \), and of a pair \( (W; Z) \), with \( \text{trace}(G_i W) + \text{trace}(F_i Z) = c_i \) for \( i = 1; \ldots; d \), and \( W \geq 0 \) and \( Z \geq 0 \), gives upper and lower bounds for the optimal value \( p \) of (1) by

\[
\log \det W \quad \text{trace}(G_0 W) \quad \text{trace}(F_0 Z) + m \quad p \quad c^T x \quad \log \det G(x):
\]

If \( x, W \) and \( Z \) have rational entries only, we can compute lower and upper bounds of \( p \) that are mathematically rigorous. For the proofs in Section [11] we have therefore developed a program \( \text{rdmc} \) (rigorous MAXDET) which calls MAXDET to find floating point values of a vector \( x \) and a pair \( (W; Z) \) satisfying the constraints. Then it approximates \( x \) and \( (W; Z) \) by rational numbers and checks whether these rational approximations satisfy the constraints. In such a case they guarantee a certified duality gap. The interested reader can download \( \text{rdmc} \) from our web page [SV05].

7 An LMI Constraint for the Inhomogeneous Minimum

In this section we will give a linear matrix inequality in the parameters \( \xi_{ij} \) of a PQF \( Q = (\xi_{ij}) \), which is satisfied if and only if the inhomogeneous minimum of \( Q \) is bounded by a constant, say \( Q \geq 1 \). For this it is crucial to observe that \( x^T Q y \) is a linear expression in the parameters \( \xi_{ij} \). The PQF \( Q = (\xi_{ij}) \) defines the inner product of a Euclidean space \( \mathbb{R}^d; ( \ ; \ ) \) by \( \langle x; y \rangle = x^T Q y \).

From the article [DDRS70], of Delone, Dolbilin, Ryshkov and Stogrin we can extract the following proposition which will be central in our further discussion.

**Proposition 7.1.** Let \( L = \text{conv} 0; v_1; \ldots; v_d \mathbb{R}^d \) be a \( d \)-dimensional simplex. Then the radius of the circumsphere of \( L \) is at most 1 with respect to \( ( \ ; \ ) \) if and only if the following linear matrix inequality (in the parameters \( \xi_{ij} \)) is satisfied:

\[
\text{BR}_L(Q) = 0:
\]

\[
\begin{align*}
0 & \quad 4 \quad (v_1; v_1) \quad (v_2; v_2) \quad \ldots \quad (v_d; v_d) \\
(v_1; v_1) & \quad (v_1; v_1) \quad (v_1; v_2) \quad \ldots \quad (v_1; v_d) \\
(v_2; v_2) & \quad (v_2; v_1) \quad (v_2; v_2) \quad \ldots \quad (v_2; v_d) \\
\vdots & \quad \vdots \quad \vdots \quad \vdots \quad \ddots \quad \vdots \\
(v_d; v_d) & \quad (v_d; v_1) \quad (v_d; v_2) \quad \ldots \quad (v_d; v_d)
\end{align*}
\]

\[\text{http://www.stanford.edu/~boyd/MAXDET.html}\]
In [DDRS70] Delone et al. used this proposition as the key ingredient for showing that the set of PQFs which determine a circumsphere of $L$ with radius of at most $R$ is convex and bounded (see Proposition 9.1). Because of the importance of the proposition and for the convenience of the reader we give a short proof here.

**Proof.** We make use of Cayley-Menger determinants. The Cayley-Menger determinant of $d + 1$ points $v_0; \ldots; v_d$ with pairwise distances $\text{dist}(v_i; v_j)$ is

$$
\text{CM}(v_0; \ldots; v_d) = \begin{vmatrix}
0 & 1 & \cdots & 1 \\
1 & \text{dist}(v_0; v_0)^2 & \cdots & \text{dist}(v_0; v_d)^2 \\
\vdots & \vdots & \ddots & \vdots \\
1 & \text{dist}(v_d; v_0)^2 & \cdots & \text{dist}(v_d; v_d)^2
\end{vmatrix}.
$$

The squared circumradius $R^2$ of the simplex $L$ equals (see for example [Ber87] Prop. 9.7.3.7)

$$R^2 = \frac{1}{2} \frac{\det \text{dist}(v_i; v_j)^2}{\text{CM}(v_0; \ldots; v_d)};$$

Replacing $\text{dist}(x; y)^2$ by $(x; x) - 2(x; y) + (y; y)$, using $v_0 = 0$, and performing elementary transformations of the determinants turns the above formula into

$$R^2 = \frac{1}{4} \frac{\det (v_i; v_j)_{1 \leq i \neq j \leq d}}{\text{det}((v_i; v_j))_{1 \leq i \neq j \leq d}};$$

The inequality $R \geq 1$ is equivalent to

$$4 \det (v_i; v_j)_{1 \leq i \neq j \leq d} + \begin{vmatrix}
0 & (v_1; v_1) & (v_2; v_2) & \cdots & (v_d; v_d) \\
(v_1; v_1) & (v_1; v_1) & (v_1; v_2) & \cdots & (v_1; v_d) \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
(v_d; v_d) & (v_d; v_1) & (v_d; v_2) & \cdots & (v_d; v_d)
\end{vmatrix} \geq 0;$$

which is equivalent to

$$4 \begin{vmatrix}
(v_1; v_1) & (v_2; v_2) & \cdots & (v_d; v_d) \\
(v_1; v_1) & (v_1; v_1) & (v_1; v_2) & \cdots & (v_1; v_d) \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
(v_d; v_d) & (v_d; v_1) & (v_d; v_2) & \cdots & (v_d; v_d)
\end{vmatrix} \geq 0;$$

The minors in the lower right are all determinants of Gram matrices and therefore non-negative. Hence, the matrix $BR_L(Q)$ is positive semidefinite. 

**Corollary 7.2.** For any $d$-dimensional simplex $L \subseteq \mathbb{R}^d$ with vertex at $0$ and $Q \subseteq S^d_+$ we have

$$BR_L(Q) \succ 0 \iff BR_L(\{0\}) \succ 0;$$

17
Example 7.3. Let us compute the matrix linear inequality $BR_L(Q) \leq 0$, $Q = \begin{pmatrix} q_{11} & q_{12} \\ q_{21} & q_{22} \end{pmatrix}$, for the two-dimensional simplex $L = \text{conv} \begin{pmatrix} 0 & 0 \\ \frac{1}{2} & \frac{1}{4} \end{pmatrix}$. We have

$$BR_L(Q) = \begin{pmatrix} 0 & 4 & q_{11} & q_{12} + 2q_{12} + q_{22} \\ 0 & q_{11} + 2q_{12} + q_{22} & 2q_{12} + q_{22} & q_{12} + 2q_{12} + q_{22} \\ q_{11} + 2q_{12} + q_{22} & 2q_{12} + q_{22} & 0 & 0 \\ 2q_{12} + q_{22} & q_{12} + 2q_{12} + q_{22} & q_{11} + 2q_{12} + q_{22} & 0 \end{pmatrix}.$$

For a Delone polytope $L$ other than a simplex the circumradius is less than or equal to 1 if and only if it is less than or equal to 1 for some $d$-dimensional simplex $L^0$ with vertices in $\text{vert} L$. Therefore we set $BR_L(Q) = BR_{L^0}(Q)$ in this case. Since a block matrix is semidefinite if and only if the blocks are semidefinite, we have the following proposition which allows us to express the constraint “$Q \leq 1$” locally by a single LMI.

**Proposition 7.4.** Let $Q = (q_{ij})_{2 \times 2} \in S^d_+$ be a PQF and let $L_1; \ldots; L_n$ be a representative system of all inequivalent $d$-dimensional Delone polytopes in $\text{Del} (Q)$. Then

$$\begin{pmatrix} 0 & \cdots & 0 & 1 \\ 0 & \cdots & 0 & \cdots & 0 & \cdots & 0 \end{pmatrix} \leq \begin{pmatrix} \text{BR}_{L_1}(Q) \\ \vdots \\ \text{BR}_{L_n}(Q) \end{pmatrix} \leq \begin{pmatrix} 0 & \cdots & 0 & \cdots & 0 & \cdots & 0 \\ 0 & \cdots & 0 \end{pmatrix}.$$

8 Algorithms

In this section we present algorithms which in theory solve the lattice covering problem and the lattice packing-covering problem in any dimension $d$.

Our algorithm for the lattice covering problem computes all locally optimal lattice coverings of a given dimension. These are only finitely many because we will see that for every fixed Delone triangulation $D$ there exists at most one PQF lying in the topological closure of the secondary cone of $D$ giving a locally optimal covering density. So, we fix a Delone triangulation and try to find the PQF which minimizes the density function in the topological closure of the secondary cone of the fixed Delone triangulation. We will formulate this restricted lattice covering problem as a determinant maximization problem.

Our algorithm for the lattice packing-covering problem operates similarly. For every Delone triangulation we have to solve a semidefinite programming problem.

8.1 Solving the Lattice Covering Problem

Recall that the covering density of a PQF $Q$ in $d$ variables is given by $Q = \frac{Q}{\det(Q)}$. Scaling of $Q$ by a positive real number leaves $Q$ invariant. Consequently, we can restrict our attention to those PQFs $Q$ with $Q = 1$. Hence, we solve the lattice covering problem if we solve the optimization problem

$$\begin{array}{ll}
\text{maximize} & \det(Q) \\
\text{subject to} & Q \text{ is a positive definite matrix;} \\
& (Q) = 1.
\end{array}$$
where the optimization variables \( q_{ij} \) are the entries of the PQF \( Q \). The major disadvantage of this optimization problem is that the second constraint is not expressible as a convex condition in the variables \( q_{ij} \) and that the problem has many local maxima. A locally optimal solution is also called a \textit{locally optimal lattice covering}.

We will circumvent this by splitting the original problem into a finite number of determinant maximization problems. For every Delone triangulation \( D \) we solve the optimization problem

\[
\begin{align*}
\text{maximize} & \quad \det(Q) \\
\text{subject to} & \quad Q \geq 0 \\
& \quad Q(2D) \geq 1.
\end{align*}
\]

The relaxation of no longer requiring \( \frac{1}{\det(Q)} \) in the third constraint does not give more optimal solutions because if \( Q \) satisfies the constraints, then so does \( \frac{1}{\det(Q)} \). Now, we have to show that this is indeed a determinant maximization problem. We have seen in Proposition 5.1 that the first constraint can be expressed with inequalities linear in \( q_{ij} \). The constraint \( \frac{1}{\det(Q)} \) can be expressed by a linear matrix inequality as in Proposition 7.4.

The optimization vector \( x \in \mathbb{R}^{d(d+1)/2} \) is the vector of coefficients of \( Q \). The linear matrix inequality \( G(x) \geq 0 \) is given by \( G(x) = Q \). We encode the two other constraints \( Q \geq 0 \) and \( \det(Q) = 1 \) by block matrices in the linear matrix inequality \( F(x) \geq 0 \). For any linear inequality which is needed to describe the secondary cone we have a \( 1 \times 1 \) block matrix. For any inequivalent \( d \)-dimensional simplex \( L \) in \( D \) we have the \( (d+1) \times (d+1) \) block matrix \( BRL(Q) \).

### 8.2 Solving the Lattice Packing-Covering Problem

Along the same lines as above we formulate the lattice packing-covering problem as a finite number of semidefinite programming problems.

Recall that the packing-covering constant of a PQF \( Q \) is \( \frac{1}{\det(Q)} \). Since \( \frac{1}{\det(Q)} \) is homogeneous we can again assume \( \det(Q) = 1 \), and the lattice packing-covering problem is equivalent to the following optimization problem.

\[
\begin{align*}
\text{maximize} & \quad \det(Q) \\
\text{subject to} & \quad Q \text{ is a positive definite matrix} \\
& \quad \det(Q) = 1.
\end{align*}
\]

A locally optimal solution of the optimization problem is called a \textit{locally optimal lattice packing-covering}.

From the previous discussion we know how to deal with the constraint \( \det(Q) = 1 \). Now, how do we maximize \( \det(Q) \)? We say that \( v \in \mathbb{Z}^{d(nf0)} \) is a \textit{shortest vector} of \( Q \) if \( Q[v] = \frac{1}{\det(Q)} \). A theorem of Voronoi (see [Vor08] Ch. 21, Th. 55, or [CS88] Ch. 21, Th. 10) implies that a shortest vector \( v \) gives the edge \( [0;v] \) in the Delone subdivision of \( Q \). In a fixed Delone subdivision \( D \) there are only finitely many (at most \( 2^{d(d+1)/2} \)) edges of form \( [0;v] \). We can maximize \( \det(Q) \) for \( Q \geq 0 \) as follows: We introduce a new variable \( C \) which we want to maximize subject to the constraints \( Q[v] \geq C \) where \( v \) runs through all edges of the form \( [0;v] \) in \( D \). This assures \( \det(Q) = C \) when \( C \) attains a maximum. All these expressions are linear in the coefficients \( q_{ij} \) of \( Q \). Hence we have to solve the following semidefinite programming problem for every inequivalent Delone triangulation \( D \) in order to solve the lattice packing-covering problem:
maximize $C$ subject to $Q^2(D)$; $(Q)1$; $Q[v] C$, where $[0;v]$ is an edge in $D$.

9 Local Optima

Since we are dealing with convex optimization problems, we can extract some structural information about uniqueness and invariance properties of locally optimal solutions. On the one hand these help us to identify exact coordinates of optimal solutions. On the other hand they allow us to decide whether we have found an isolated locally optimal solution or not.

9.1 Properties of Local Optima

Most of the desired properties follow from the special structure of sets with PQFs $Q$ attaining certain fixed values $(Q)$, $(Q)$ or $\det(Q)$. Let $L = \text{conv}v_0;v_1;\ldots;v_d R^d$ denote a $d$-dimensional simplex and $D$ a Delone triangulation. Then we consider the sets

$$V_L = fQ^2 S_d^0 : \det(Q)j 0g,$$
$$\Psi_L = fQ^2 S_d^0 : \det(Q)j= 0g;$$
$$W_D = V_L \setminus (D).$$

Hence, by Corollary 7.2 and Proposition 7.4 the PQFs $Q^2 W_D$ are those with $(Q)1$ in $(D)$. Further, for $D > 0$ and $> 0$ we consider

$$D_D = fQ^2 S_d^0 : \det(Q) D g;$$
$$M = fQ^2 S_d^0 : (Q) q.$$ 

The following is known (see [DDRS70], [Rys74]) and was partially discussed in previous sections:

**Proposition 9.1.** Let $L = \text{conv}v_0;v_1;\ldots;v_d R^d$ be a $d$-dimensional simplex, $D$ a Delone triangulation, $D > 0$ and $> 0$. Then

1. $V_L$, and therefore $W_D$, is convex and bounded.
2. $\Psi_L$ is a smooth (regular) hypersurface.
3. $D_D$ is unbounded, strictly convex and has a smooth boundary.
4. $M$ is unbounded and convex and has a piecewise linear boundary.
5. $D_D$ and $M$ are invariant with respect to the action of $\text{GL}_d(Z)$ on $S_d^0$.

As a consequence of these properties, it is not hard to derive the following proposition (see [DDRS70], [Rys74]).

**Proposition 9.2.** Let $D$ be a Delone triangulation.
1. The set of PQFs in $\mathcal{D}$ attaining $\min_{Q \in \mathcal{D}} Q$ is a single PQF, together with all of its positive multiples. It is invariant with respect to the action of $\mathcal{D}$'s automorphism group $Aut(\mathcal{D}) = \{U \in GL_d(\mathbb{Z}) : DU = DU\}.$

2. The set of PQFs in $\mathcal{D}$ attaining $\min_{Q \in \mathcal{D}} Q$ is convex and contains a subset which is invariant with respect to $Aut(\mathcal{D}).$

A first, but non-geometric proof of property 1 was given by Barnes and Dickson [BD67]. There they also observed, as Ryshkov [Rys74] did for the lattice packing-covering problem, that it suffices to optimize among all PQFs whose automorphism group contains the group $Aut(\mathcal{D}).$

Corollary 9.3. If $Q$ is a local optimum of the lattice covering or lattice packing-covering problem among all PQFs in $\mathcal{D}$ whose automorphism group contains $Aut(\mathcal{D})$, then $Q$ is a locally optimal solution.

Note that the statement above holds only if $Q$ lies in the interior of the secondary cone. For local optima on the boundary of secondary cones we may apply the following trivial proposition.

Proposition 9.3. A PQF $Q$ is a locally optimal solution with respect to $\mathcal{D}$ if and only if it is an optimal solution for all Delone triangulations $\mathcal{D}$ with $Q \in \mathcal{D}.$

There probably exist two locally optimal solutions with respect to $\mathcal{D}$ in dimension 5 which both lie on the boundary of some secondary cones (see Section 11, proof of Theorem 11.2). In dimension 5 and lower every locally optimal solution with respect to $\mathcal{D}$ lies in the interior of some secondary cone. However, in higher dimension there exist locally optimal solutions lying on the boundary. The Leech lattice gives such an example as recently shown by the authors in [SV04].

### 9.2 Rigorous Certificates

Using convex optimization software to solve the covering or packing-covering problem, we are often limited to determining a certain certified range (see Section 6) in which the optimum value is attained. To use Proposition 9.3 it is desirable to decide computationally whether or not the optimum is attained on the boundary or even on a specific facet of $\mathcal{D}$. In many cases this is possible by using the following proposition which is a simple consequence of the convexity of determinant maximization problems.

Proposition 9.4. Consider the determinant maximization problem

\[
\begin{align*}
\text{minimize} & \quad f(\mathbf{x}) \\
\text{subject to} & \quad G(\mathbf{x}) \geq 0 \quad \text{and} \quad F(\mathbf{x}) = 0; \\
\end{align*}
\]

where $f(\mathbf{x}) = c^T \mathbf{x} \log \det G(\mathbf{x}).$

1. Let $y_1$ be the optimal solution of (4), and let $y_2$ be the optimal solution of (4) with the additional constraint $F(\mathbf{x}) = 0$. If $f(y_1) < f(y_2)$, then $F(y_2) = 0.$

2. Let $y_1$ be an optimal solution of (4) with the additional linear constraint $n^T \mathbf{x} = 0$, and let $y_2$ be an optimal solution of (4) with the additional linear constraint $n^T \mathbf{x} = 0.$

(a) If $f(y_1) < f(y_2)$, then $n^T y_2 = 0.$

(b) If $f(y_1) > f(y_2)$, then $n^T y_2 < 0.$
Let $Q_{\text{opt}}$ denote a PQF with $(Q_{\text{opt}}) = 1$ attaining an optimum in $(D)$ for $f$. The lattice packing-covering case is similar. Let $u$ and $v$ be a lower and an upper bound for a minimum of $f$ over $f$ on $D(Q)$.

Here and in the sequel we use $D(Q)$ as an abbreviation for the LMI in Proposition 7.4, guaranteeing that the circumradius (with respect to $Q$) of all the simplices of the triangulation $D$ is at most 1.

The first part of Proposition 9.5 gives a sufficient criterion for $Q_{\text{opt}}$ lying on the boundary of $D$. Suppose the upper bound of $f$ on $D(Q)$ is 1 as an abbreviation for the LMI in Proposition 7.4, guaranteeing that the circumradius (with respect to $Q$) of all the simplices of the triangulation $D$ is at most 1.

The first part of Proposition 9.5 gives a sufficient criterion for $Q_{\text{opt}}$ lying on the boundary of $D$. Suppose the upper bound of $f$ on $D(Q)$ is 1 as an abbreviation for the LMI in Proposition 7.4, guaranteeing that the circumradius (with respect to $Q$) of all the simplices of the triangulation $D$ is at most 1.

Suppose the upper bound of $f$ on $D(Q)$ is 1 as an abbreviation for the LMI in Proposition 7.4, guaranteeing that the circumradius (with respect to $Q$) of all the simplices of the triangulation $D$ is at most 1.
neighborhood of \( Q \), is equal to the intersection \( \cap_{Q \in \tilde{V}_L} \tilde{V}_L \). Therefore, the normal cone of \( \tilde{W}_D \) at \( Q \) is equal to \( \text{conef}_{g_L(Q)}: Q, L, g \) (see [Sch93], Th. 2.2.1) and the assertion follows.

By Proposition 9.1, the boundary of \( D_{\text{det}(Q)} \) is smooth at \( Q \), hence up to scaling there is a uniquely determined outer normal. The following is well known (cf. Proposition 10.3 and its detailed proof in [Val02], Prop. 8.2.2).

**Proposition 9.7.** The normal cone of \( D_{\text{det}(Q)} \) at \( Q \) is given by \( \text{conef}_{Q} g_L \).

The normal cone of \( M \) at a boundary point \( Q \) is determined by the shortest vectors of \( Q \), that is, by those \( v \in Z^d \) for which the homogeneous minimum \( (Q) \) is attained. Recall that \( Q[v] = \) for a fixed \( v \in Z^d \) if \( 0 \) is linear in the parameters \( q_{ij} \), hence this condition defines a hyperplane in \( S^d \).

**Proposition 9.8.** For \( v \in Z^d \) let \( v_L, v_S \) be the normal vector of the hyperplane \( (Q)[v] = (Q) g \) with \( hQ; v_L i = (Q) \) and \( v_S = (Q) g \). Then, the normal cone of \( M \) at \( Q \) is given by \( \text{conef}_{v_L} Q[v] = (Q) g \).

**Proof.** This follows immediately from [Sch93], Th. 2.2.1.

Note, that a normal vector \( v_L \) depends on the chosen inner product. For example for practical computations it is convenient to identify \( S^d \) with \( R^{d(d+1)/2} \) and to use the standard inner product \( hQ; v_L i = v_{ij} q_{ij} v_{ij} \) and \( v_L = (v_{ij}) \) with \( v_{ij} = (2 i j) v_L v_{ij} \).

### 9.3.2 Interior Cases

Because of the convexity of \( D_{\text{det}(Q)} \), \( M_{\text{det}(Q)} \) and \( \tilde{W}_D \) a separating hyperplane at a PQF \( Q \) of \( \tilde{W}_D \) with \( (Q) = 1 \) and one of the other two sets yields a necessary and sufficient condition for \( Q \) to be a locally optimal solution to either the lattice covering or the lattice packing-covering problem. Therefore a necessary and sufficient condition can be derived from the normal cones at \( Q \) with respect to these sets.

**Proposition 9.9.** Let \( D \) be a Delone triangulation, and let \( \tilde{W}_D \) be a PQF with \( (Q) = 1 \).

1. ([BD67]) Then, \( Q \) is a locally optimal solution to the lattice covering problem if and only if
   \[ \text{conef}_{\tilde{W}} Q \cap g_L \cap \text{conef}_{g_L} (Q) : L, \tilde{D} \text{ and } Q, L, g \in \tilde{W}_D \].

2. Then, \( Q \) is a locally optimal solution to the lattice packing-covering problem if and only if
   \[ \text{conef}_{g_L} (Q) : L, \text{ and } Q, L, g \in \tilde{W}_D \].

### 9.3.3 Boundary Cases

Note that the foregoing proposition does not give criteria for PQFs \( Q \) on the boundary of some secondary cones. In such a case we need to replace \( \text{conef}_{g_L} (Q) : L, \tilde{D} \) by a generalized expression. That is done by considering for each Delone triangulation \( D \) with \( Q, L, g \) the normal cone \( C_D(Q) \) of \( \tilde{W}_D \) at \( Q \). We have \( C_D(Q) = \text{conef} N_1 \cap N_2 \) with outer normal vectors \( N_1 = \text{conef}_{g_L} (Q) : L, \tilde{D} \) and \( N_2 = \text{conef}_{g_L} (Q) : L, \tilde{D} \). They are considered before, and outer normal vectors

\[ N_2 = fN, 2 S^d : iN, \, i = (x, \mu, \gamma), \] for a pair \( (L, \tilde{D}) \) of adjacent simplices of \( D \) with \( g_L, \mu, \gamma \) of \( Q \) is equal to \( 0 \) from facets of \( \tilde{D} \) containing \( Q \). Since \( \tilde{D} \) has a smooth boundary a necessary condition for a local covering optimum at \( Q \) is the convexity of \( \tilde{W}_D \) at \( Q \) which is equivalent to \( (L, \tilde{D}) \) of \( Q \) is a boundary condition. In the case of the lattice packing-covering problem, this convexity condition is not necessary for a local optimum. The following proposition however gives sufficient conditions for a local optimum in case the convexity condition is satisfied.
**Proposition 9.10.** Let \( Q \in \mathbb{S}^d_\mathbb{D} \) be a PQF with \( \langle \mathcal{Q} \rangle = 1 \).

1. Then, \( Q \) is a locally optimal solution to the lattice covering problem if and only if

\[
\text{cone}_Q^0 \mathbb{g} \cap \mathcal{C}_0 (\mathcal{Q}) \neq \emptyset ;
\]

\[
Q \in \mathbb{D}.
\]

2. Then, \( Q \) is a locally optimal solution to the lattice packing-covering problem if

\[
\text{cone}_V^0 \mathbb{g} \cap \mathcal{C}_0 (\mathcal{Q}) \neq \emptyset ;
\]

\[
Q \in \mathbb{D}.
\]

**Proof.** The set \( \bigcap_{Q \in \mathbb{S}^d_\mathbb{D}} \mathcal{C}_0 (\mathcal{Q}) \) contains all common outer normal vectors of the sets \( \mathcal{W}_D \) with \( Q \in \mathbb{D} \) at \( Q \). In particular, \( \mathcal{C}_0 (\mathcal{Q}) \) is empty if and only if \( \mathcal{W}_D \) is not convex at \( Q \). If convex, then a separating hyperplane of \( \mathcal{W}_D \) and \( \det (\mathcal{Q}) \) at \( Q \) is sufficient for a local optimum at \( Q \). The assertion then follows by Propositions 9.7 and 9.8.

**9.4 Conditions for Isolated Local Optima**

Locally optimal solutions to the lattice packing-covering problem may not be isolated optima, in contrast to solutions to the lattice covering problem. To determine computationally if a given locally optimal solution \( Q \) is isolated, we have to check if there exists a segment \( [Q ; Q^*] \) which lies in the boundary of \( M \) at \( Q \) and in the boundary of \( \mathcal{W}_D \) at \( Q \).

**Proposition 9.11.** Let \( D \) be a Delone triangulation and let \( Q \in \mathbb{D} \) be a locally optimal solution to the lattice packing-covering problem with \( \langle \mathcal{Q} \rangle = 1 \). Then \( Q \) is not an isolated local optimum if and only if there exists an \( S \in \mathbb{D} \) with

1. \( h_V; S = 0 \) for all \( v \in \mathbb{Z}^d \) with \( \langle v \rangle = \langle \mathcal{Q} \rangle \),
2. \( h_{\mathcal{L}} (Q); S = 0 \) for all \( L \in \mathbb{D} \) with \( Q \in \mathcal{L} \),
3. \( h_{\mathcal{L}} (Q); S = 0 \) for all \( L \in \mathbb{D} \) with \( Q \in \mathcal{L} \) and \( h_{\mathcal{L}} (Q); S = 0 \).

**Proof.** The first condition says that there exists an \( \mathcal{W}_L \) so that the segment \( [Q ; Q + \mathcal{W}_L] \) lies in \( M \) at \( Q \) because \( M \) at \( Q \) has a piecewise linear boundary. The second condition together with the second condition plus the local optimality of \( Q \) are equivalent to the fact that \( S \) is in the tangent space of \( V_L \) at \( Q \) and in the tangent space of \( M \) at \( Q \). Thus \( Q + \mathcal{W}_L \) is in the boundary of \( \mathcal{W}_D \) for sufficiently small \( \mathcal{W}_L \). If and only if the corresponding smooth hypersurfaces \( \mathcal{L} \) have curvature 0 in direction \( S \). This is equivalent to \( S \) being an eigenvector of eigenvalue 0 of the Hessian \( h_L (Q) = \text{hess } j_{\mathcal{B}}(L, j(Q)) \) which is the third condition. Hence, all three conditions are fulfilled if and only if there exists a segment \( [Q ; Q^*] \) in the boundary of the two sets \( M \) and \( \mathcal{W}_D \), where \( Q^* = Q + m \notin (1 ; 2)S \).

Note again, that the condition applies only if \( Q \) is in the interior of a secondary cone. A similar sufficient condition for PQFs on the boundary of secondary cones can be attained by replacing \( g_L (Q) \) in 2 and 3 with the rays of the normal cone \( \mathcal{C}_0 (\mathcal{Q}) \) of \( \mathcal{W}_D \) at \( Q \) (see Proposition 9.10), if such exist.

**Question 9.12.** Does there exist a locally optimal solution to the lattice packing-covering problem which is not isolated?
Note that a positive answer to the following question would imply the existence of non-isolated locally optimal solutions.

**Question 9.13.** Does there exist a (locally optimal) solution to the lattice-packing covering problem, which does not have all the symmetries of the corresponding Delone subdivision?

### 10 Local Lower Bounds via Moments of Inertia

In this section we give simple and efficiently computable local lower bounds for the lattice covering density and the lattice packing-covering constant. These bounds are “local” in the sense that they only apply to those PQFs lying in the topological closure of the secondary cone of a given Delone triangulation. For their computation we only need to know the coordinates of the simplices of the considered Delone triangulation. They are therefore useful tools in a heuristic search for “good” PQFs. The method goes back to Ryshkov and Delone. It is called the method of the moments of inertia because the central idea in its proof is analogous to the Parallel Axis Theorem of Steiner in classical mechanics. This analogy is explained in [AM03].

Let $P \subseteq \mathbb{R}^d$ be a finite set of points in $d$-dimensional Euclidean space $\mathbb{R}^d$. We interpret the points of $P$ as masses with unit weight. The moment of inertia of the points about a point $x \in \mathbb{R}^d$ is defined as $I_x(P) = \sum_{v \in P} \text{dist}(x; v)^2$. The centroid of $P$ (center of gravity) is given by $m = \frac{1}{|P|} \sum_{v \in P} v$. From the equations

\[
\text{dist}(x; v)^2 = (x - m)^2 + \text{dist}(m; v)^2 + 2(x - m;m; v),
\]

and $\sum_{v \in P} m; v = 0$, we derive Apollonius’ formula (see [Ber87]:9.7.6)

\[
I_x(P) = \sum_{v \in P} \text{dist}(x; v)^2 + I_m(P).
\]

Hence, the moment of inertia of $P$ about the centroid $m$ is minimal.

If the points of $P$ form the vertices of a $d$-dimensional simplex, then (5) gives a relationship between the radius of the circumsphere $R$, the center of the circumsphere $c$, and the moment of inertia about the centroid $m$ of $P$:

\[
R^2 = \frac{I_c(P)}{d+1} = \text{dist}(c; m)^2 + \frac{I_m(P)}{d+1}.
\]

We can compute $I_m(P)$ using only the edge lengths of the simplex $P$. For every $w \in \text{vert} P$ we have by definition $I_w(P) = \sum_{v \in P} \text{dist}(w; v)^2$. Summing up and using (5) gives

\[
I_m(P) = \frac{1}{d+1} \sum_{w \in P} \text{dist}(w; m)^2 + \frac{1}{d+1} \sum_{v \in P} \text{dist}(w; m)^2 = 2(d+1)I_m(P).
\]

So, we get

\[
I_m(P) = \frac{1}{d+1} \sum_{w \in P} \text{dist}(w; m)^2.
\]

Let $D$ be a Delone triangulation of $\mathbb{R}^d$, let $L_1; \ldots; L_n$ be the $d$-dimensional simplices of the star of a lattice point (say for example the origin), and let $m_i$ be the centroid of $L_i$, $i = 1; \ldots; n$. The arithmetical mean of the moments of inertia about the centroids of $L_i$ with respect to a PQF $Q$ is defined to be

\[
I_D(Q) = \frac{1}{n} \sum_{i=1}^n I_m(L_i).
\]
and is called the central moment of inertia of $D$ with respect to $Q$. Note that we are now dealing with the inner product given by $Q$ with $\text{dist}(x; y)^2 = Q[x - y]$ and that $I_D(Q)$ is linear in the parameters $q_{ij}$ of $Q$.

**Proposition 10.1.** The central moment of inertia of $D$ with respect to $Q$ yields a lower bound for the inhomogeneous minimum of $Q$ if $D$ is a refinement of $\text{Del}(Q)$. In this case we have

$$
(Q) \leq \frac{1}{d+1} I_D(Q);
$$

**Proof.** Let $R_i$ be the radius and $c_i$ be the center of the circumsphere of the simplex $L_i$, then

$$
(Q) = \max_{i=1}^{n} \frac{R_i^2}{d+1} = \max_{i=1}^{n} \frac{\text{dist}(c_i; m_i)^2 + \frac{I_m(L_i)}{d+1}}{d+1} = \frac{1}{d+1} I_D(Q);
$$

\[\square\]

To find lower bounds for the lattice covering density or for the lattice packing-covering constant, we have to minimize the linear function $I_D$ over all PQFs with a fixed determinant, or with a fixed homogeneous minimum, respectively. As in previous sections, we consider $S^d$ as a Euclidean space with inner product $\langle \cdot, \cdot \rangle$.

**Proposition 10.2.** There exists a PQF $F \in S^d_{>0}$ with $I_D = \langle F; \cdot \rangle$.

**Proof.** Since $I_D$ is a linear function, there is a $F \in S^d$ with $I_D(Q) = \langle F; Q \rangle > 0$. Since $S^d_{>0} = \mathbb{R}^d_{>0}$, meaning that $S^d_{>0}$ is a self-dual cone, we have $F \in S^d_{>0}$.

Because of the preceding proposition, minimizing the linear function $I_D$, hence $\langle F; \cdot \rangle$, over all PQFs with a fixed determinant $D$ is geometrically equivalent to finding the unique PQF on the boundary of $D$ — the determinant-D -surface — that has a supporting hyperplane with normal $F$ (see Proposition 9.7). Thus we derive the following proposition (see [Val03] Prop. 8.2.2 for a detailed proof).

**Proposition 10.3.** A linear function $f(\cdot) = \langle F; \cdot \rangle$ with $F \in S^d_{>0}$ has a unique minimum on the determinant-D -surface. Its value is $\langle F; F \rangle$ and the minimum is attained at the PQF $F \in S^d_{>0}$. 

Now we can plug Proposition 10.1 and Proposition 10.3 together. This yields a local lower bound for the covering density of a PQF.

**Proposition 10.4.** Let $D$ be a Delone triangulation. Let $Q$ be a PQF for which $D$ is a refinement of $\text{Del}(Q)$. Then we have a lower bound for the covering density of $Q$:

$$
(Q) \left( \frac{d}{d+1} \det F \right) \leq s;
$$

where $F$ is the positive definite matrix given by the equation $I_D(Q) = \langle F; Q \rangle$. Here and in the sequel we denote the local lower bound for the Delone triangulation $D$ by $(D)$.
Proof. By Proposition 10.3, \( I_D = hF; i \) has the unique minimum \( \frac{D}{d \cdot \det F} \) on the determinant-\( D \)-surface. Using this with \( D = \det Q \) and applying Proposition 10.1 we get the lower bound \( D \) for \( Q \), because of

\[
(Q) = (d + 1) = \frac{(Q)^d}{\operatorname{det} Q} \frac{I_D(Q)}{d + 1} = \frac{d^d \det Q \det F}{(d + 1)^d \det Q} = \frac{d}{d + 1} \frac{d}{\det F}.
\]

For a local lower bound on the lattice packing-covering constant we minimize the linear function \( I_D = hF; i \) over all PQFs with a fixed homogeneous minimum. In analogy to the above, we replace the determinant-\( D \)-surface (the boundary of \( D_D \)) by the homogeneous-minimum-\( D \)-surface (the boundary of \( M_D \)).

**Proposition 10.5.** Let \( \epsilon \) be a positive number. Let \( D \) be a Delone triangulation and let \( Q \) be a PQF for which \( D \) is a refinement of \( \Delta_{\in L(Q)} \). Further, let the minimum of the linear function \( I_D = hF; i \) on the homogeneous-minimum-\( D \)-surface be attained at a PQF \( Q_{F}; i \). Then we have a lower bound for the packing-covering constant of \( Q \):

\[
(Q) = (d + 1) = 2 \frac{hF; Q_{F}; i}{(d + 1)}.
\]

Proof. The PQF \( Q_{F}; i \) attains the minimum of \( hF; i \) among PQFs in \( M_Q \). Applying Proposition 10.1 gives the desired lower bound:

\[
(Q) = (d + 1) = 2 \frac{hF; Q_{F}; i}{(d + 1)}.
\]

It is difficult in practice to obtain \( Q_{F}; i \) and therefore the lower bound of the proposition. Instead, if we minimize \( I_D \) on an approximation \( M^D \) of \( M \), suitable for \( D \), things become easier. We set

\[
M^D = \{ Q | 2 S^d_{\geq 0} : Q [v] \text{ for all } v \in \mathbb{Z}^d \text{ with } [0;v] \leq D \}.
\]

Now finding the minimum of \( I_D \) on \( M^D \) reduces to a linear program with finitely many constraints. By looking at equation (6) it is easy to see that this linear program is bounded from below since every summand is at least \( \epsilon \). Because of \( M \) \( M^D \) we obtain the following practically useful lower bound for \( Q \).

**Proposition 10.6.** Let \( \epsilon \) be a positive number. Let \( D \) be a Delone triangulation and let \( Q \) be a PQF for which \( D \) is a refinement of \( \Delta_{\in L(Q)} \). Further, let the minimum of the linear function \( I_D = hF; i \) on \( M \) be attained at a PQF \( Q_{F}; i \). Then we have a lower bound for the packing-covering constant of \( Q \):

\[
(Q) = (d + 1) = 2 \frac{hF; Q_{F}; i}{(d + 1)}.
\]
11 Computational Results

In Section 8 we developed algorithms for the solution of the lattice covering and the lattice packing-covering problem. Here, we want to demonstrate that these algorithms are not purely of theoretical interest. We implemented the algorithms in C++, using the package MAXDET of Wu, Vandenberghe and Boyd and the package lrs of Avis as subroutines. The interested reader can download the implementation from our web page [SV05].

With the implemented algorithm we are able to determine the solution of the lattice covering problem and the lattice packing-covering problem in dimensions \( d = 1, \ldots, 5 \). This hereby reproduced the known results. For dimension \( d = 5 \) this computation took on a 2GHz Intel Pentium computer less than 90 minutes. By our computations we get a conjectural list of approximations of all locally optimal solutions. In Section 11.1 we give some details.

More important, with the help of a heuristic method, which we describe in Section 11.2, this approach produces interesting new lattices in dimensions \( d = 6 \) which give better coverings and packing-coverings than previously known ones. We analyze them in Section 11.3 and in Section 11.4 where we give rigorous proofs of some facts concerning these lattices which we found experimentally. This analysis turned out to be fruitful: The new 6-dimensional lattices were our starting point to find new best-known covering lattices in dimensions 7 and 8. We describe the 7-dimensional case in Section 11.5. The 8-dimensional case is explained in [SV04].

11.1 Dimensions 1, \ldots, 5

We described the solutions to both problems for the 1, 2, and 3-dimensional cases in Section 3 and 4. Since in these cases there is only one type of Delone triangulation, these results are computationally rather trivial.

The 4-dimensional case requires more work because there are three inequivalent Delone triangulations in dimension 4. Baranovskii [Bar65] and independently Dickson [Dic67] found all three inequivalent locally optimal solutions to the lattice covering problem in dimension 4. Earlier Delone and Ryshkov showed that the lattice \( A_4 \) gives the best 4-dimensional lattice covering without determining all locally optimal solutions. We describe their approach in Section 11.2.

For the lattice packing-covering problem the 4-dimensional case was resolved by Horvath [Hor82]. He shows that there exist, as in the covering case, three isolated, locally optimal solutions — one for each Delone triangulation. It is interesting that Horvath’s optimal packing-covering lattice \( H_{o4} \) does not belong to the family of root lattices and their duals. An associated PQF is

\[
Q_{H_{o4}} = \begin{pmatrix}
0 & 2 & 1 & 1 & 1 & 0 & 4 & 1 & 2 & 2 & 1 \\
1 & 2 & 1 & 1 & 1 & 0 & 3 & 1 & 4 & 2 & 2 \\
1 & 1 & 2 & 0 & 3 & 1 & 1 & 4 & 2 & 2 & 1 \\
1 & 1 & 0 & 2 & 2 & 2 & 1 & 4 & 2 & 2 & 1
\end{pmatrix}.
\]

The first summand, associated to the best packing lattice \( D_4 \), lies on an extreme ray of the secondary cone belonging to \( Q_{H_{o4}} \).

In a series of papers Ryshkov and Baranovskii solved the 5-dimensional lattice covering problem. In [Rys73] Ryshkov introduced the concept of C-types. Two Delone triangulations are of the same C-type if their 1-skeletons (the graph consisting of vertices and edges of the triangulation) coincide. He gave an algorithm to find all inequivalent C-types in any given dimension. He computed that there are 3 inequivalent C-types in dimension 4 and that there are 76 inequivalent C-types in dimension 5. Using this list Baranovskii
and Ryshkov enumerated 221 (of 222) inequivalent 5-dimensional Delone triangulations in [BR73]. They described the triangulations in more detail in [BR75]. In the last paper of the series [RB75] they showed that the lattice $A_5$ provides the least dense 5-dimensional lattice covering. In their proof they do not find all locally optimal lattice coverings. By using estimations (the method explained in Section 11.2 is one of their main tools) they merely show that all local minima exceed the covering density of $A_5$. As mentioned in Section 5.3 Ryshkov and Baranovskii missed one Delone triangulation. Fortunately, this does not give a thinner lattice covering than $A_5$.

Using our algorithm, and the techniques described in Section 9 to obtain certificates we produced a list of inequivalent locally optimal lattice coverings in dimension 5. This list is conjecturally complete and gives approximations of the local optima. The computation, including all certificates, takes about 90 minutes on a 2GHz Intel Pentium computer. We can prove the following theorem rigorously.

**Theorem 11.1.** In dimension 5, there exist at least 216 and at most 218 inequivalent, local minima of the lattice covering density function $f$, ranging from approximately $2 \cdot 124286$ to approximately $2 \cdot 757993$. All of them are attained in the interior of their secondary cones.

**Proof.** We take a complete list of 222 inequivalent secondary cones, generated by scc (see Section 5 and our web page [SV05]). For each cone, we applied the program coop (covering optimizer), which is based on rmd (rigorous MAXDET) and available on our web page [SV05]. It computes certified bounds for within the closure of a given secondary cone by solving the determinant maximization problem described in Section 8.1. The bounds for the duality gap described in Section 6 are mathematical rigorous, since we use rational arithmetic only. Solving additional determinant maximization problems as described in Section 9.2, the program then tries to obtain certificates for the approximated local optimum to be attained in the interior or on the boundary of the secondary cone. As a result, there are 216 certified local optima attained in the interior of secondary cones and 4 certified non-optima attained on the boundary. This leaves two cases which might be local optima, attained in the interior of their secondary cones. However, if they are attained on the boundary (and the numerical evidence strongly supports this) then they are not local optima, since the corresponding secondary cones adjacent to the facets in question have a smaller local minimum. \(\square\)

Note that our computations prove rigorously that the PQF of Barnes and Trenergy [BT72] yields the second best locally optimal lattice covering with density of approximately $2 \cdot 230117$.

In 1986, Horvath [Hor86] solved the lattice packing-covering in dimension 5. The proof is about 70 pages long (private communication). As in dimension 4, Horvath’s lattice $H_0$ is not among previously known ones. An associated PQF is

\[
Q_{H_0} = \begin{bmatrix}
0 & 6 & 0 & 0 & 2 & 0 & 1 \\
1 & 3 & 2 & 2 & 2 & 2 & 1 \\
2 & 2 & 1 & 1 & 0 & 0 & 0 \\
1 & 2 & 0 & 0 & 0 & 0 & 0 \\
1 & 1 & 2 & 0 & 0 & 0 & 0 \\
1 & 1 & 0 & 0 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 & 1 & 2 & 1
\end{bmatrix}
\]

Again, the first summand is associated to the best packing lattice $D_4$. It has rank 4 and lies on an extreme ray of the secondary cone belonging to $Q_{H_0}$.

By applying propositions of Section 9 we were able to reproduce Horvath’s result and moreover to attain a list of locally optimal solutions. Again this list is conjecturally complete and gives approximations of the local optima. Compared to the covering problem, there are many more secondary cones that contain no locally optimal solution. The computation, including all certificates, also takes about 90 minutes on a 2GHz Intel Pentium computer. We can prove the following theorem rigorously.
Theorem 11.2. In dimension 5, there exist at least 47 and at most 75 local minima of the lattice packing-covering constant, ranging from approximately 1.449456 to approximately 1.557564. At least 45 of them are attained in the interior of their secondary cones.

Proof. As for the proof of Theorem 11.1, we used the complete list of 222 inequivalent secondary cones, generated by scd. For each cone, we applied the program pacoop (packing-covering optimizer), which is also based on rmd and available on our web page [SV05]. It computes certified bounds for within the closure of a given secondary cone by rigorously solving the semidefinite program described in Section 8.2. Again the program tries to obtain certificates for the approximated local optimum to be attained in the interior or on the boundary of the secondary cone. As a result, there are 45 certified local optima attained in the interior of secondary cones and 147 certified non-optima attained on the boundary. There are 30 of 222 remaining cases in which the program pacoop did not give a certificate for the optimum to be attained in the interior or the boundary of the secondary cone. However, if all of them are attained on the boundary (and the numerical evidence strongly supports this), there are two local optima on the common boundary of three inequivalent secondary cones each. Thus there exist at least 47 local optima as claimed.

11.2 Heuristic Methods

Before going to dimension 6, let us explain one important heuristic method, which is essential for finding the new lattices. One of the biggest problem in finding good lattice coverings or packing-coverings in dimension 6 and higher is that it is not apriori clear which Delone triangulations admit good ones. Solving a determinant maximization problem is a rather time consuming task and there are a lot of inequivalent Delone triangulations to consider. So a desirable tool is a fast computable lower bound, as described in Section 10.

We view the set of Delone triangulations as an undirected labeled graph. A node represents a Delone triangulation and two nodes are adjacent if their Delone triangulations are bistellar neighbors. Let \( D \) be a Delone triangulation. We label its node by the local lower bound \((D)\) or \((\overline{D})\). We can use the labeling in two different ways.

On the one hand it is clear that if the labeling of a node is large, then the considered Delone triangulation does not admit a good lattice covering and lattice packing-covering respectively. Ryshkov and Delone [DR63] solved the lattice covering problem in dimension 4 by this method. However, the five-dimensional lattice covering problem cannot be solved in this way. From the 222 inequivalent Delone triangulations there are 20 whose local lower bound is smaller than \((\overline{A}_5)\).

On the other hand we can hope that \( D \) admits a good lattice covering or packing-covering if the local lower bound is small. In dimension 6 the hope that good local lower bounds yield good lattice coverings is partially fulfilled. We report on a typical example: We started from the Delone triangulation of Voronoi’s principal form of the first type and took a random walk of length 50. Then, we found a node labeled by \( (\overline{D}) \) 2\( \times \)85149. From this we proceeded by taking a neighboring node having the smallest local lower bound. By repeating this greedy strategy we resulted in a node labeled by \( (D) \) 2\( \times \)18034. This node is interesting for several conjectural “extremeness” properties. It yields the smallest known local lower bound and it has the largest known number of neighbors, namely 130. As we will see in the next section there exists a locally optimal lattice covering which belongs to this node with covering density of approximately 2\( \times \)466125. At present this is the second best known 6-dimensional lattice covering which is locally optimal. Furthermore we will see that there exists a locally optimal lattice packing-covering belonging to this node which currently defines the best known 6-dimensional lattice packing-covering.
11.3 New Six-Dimensional Lattices

We have not been able to solve the lattice covering problem in this dimension. However we found some new interesting covering lattices. As we reported in Section 3, Ryshkov [Rys67] asked what is the first dimension \( d \) where \( A_d \) does not give the least dense lattice covering.

A classification of all inequivalent Delone triangulations in dimension 6 is not within reach. So we can not use our algorithm to find the best lattice covering. Nevertheless we ran it partially to find good lattice coverings. Since there are no other good lattice coverings in the neighborhood of Voronoi’s principal form of the first type, we used the heuristic method described in the previous section. In this manner we found about 100 inequivalent secondary cones containing lattice coverings better than \( A_6 \). Thus, we can give an answer to Ryshkov’s question:

**Theorem 11.3.** Dimension \( d = 6 \) is the smallest dimension where the lattice \( A_d \) does not give the least dense lattice covering.

**Proof.** This theorem follows from Theorem 11.7 or from Theorem 11.8.

Two of the new lattice coverings were strikingly good. Of course, by the computational optimization we only got numerical estimates of these coverings.

The now second best-known lattice covering which is locally optimal was quite easy to find: running our heuristic method described above finds this lattice covering in most of the trials. An approximation is given by the PQF

\[
\begin{pmatrix}
0 & 0.9982 & 0.5270 & 0.4170 & 0.5270 & 0.5270 & 1.0541 \\
0 & 0.5270 & 1.9982 & 0.4170 & 0.5270 & 0.5270 & 1.0541 \\
0 & 0.4170 & 0.4170 & 2.1082 & 1.0541 & 0.4170 & 0.8341 \\
0 & 0.5270 & 0.5270 & 1.0541 & 1.9982 & 0.5270 & 0.4170 \\
0 & 0.5270 & 0.5270 & 0.4170 & 0.5270 & 1.9982 & 1.0541 \\
1.0541 & 1.0541 & 0.8341 & 0.4170 & 1.0541 & 2.1082 &
\end{pmatrix}
\]

and its covering density is \( \frac{\sqrt{2}}{\sqrt{6}} \times 2.466125 \). The Delone subdivision is a triangulation and its secondary cone has 130 facets. The local lower bound is approximately 2.318034.

For a while we thought that this might by the best lattice covering in dimension 6, but then

\[
\begin{pmatrix}
0 & 2.0550 & 0.9424 & 1.1126 & 0.2747 & 0.9424 & 0.8153 \\
0 & 0.9424 & 1.9227 & 0.5773 & 0.7681 & 0.3651 & 0.8651 \\
1.1126 & 0.5773 & 2.9300 & 0.4934 & 0.5773 & 0.9804 \\
0 & 0.2747 & 0.7681 & 0.4934 & 1.7550 & 0.7681 & 0.7681 \\
0 & 0.9424 & 0.3651 & 0.5773 & 0.7681 & 1.9227 & 0.3651 \\
0 & 0.8153 & 0.3651 & 0.9804 & 0.7681 & 0.3651 & 1.9227
\end{pmatrix}
\]

with covering density \( \frac{\sqrt{2}}{\sqrt{6}} \times 2.464802 \) came up. The Delone subdivision is a triangulation and its secondary cone has 100 facets. The local lower bound is approximately 2.322204. After this, we did not find any further lattice covering records in dimension 6. Furthermore, we did not find a 6-dimensional Delone triangulation whose secondary cone has more than 130 facets or whose local lower bound is less than 2.318034.
Nevertheless, in the secondary cone of $Q^6_{E_6}$ we found the PQF

\[
\begin{array}{ccccccc}
0 & 2.0088 & 0.5154 & 0.5154 & 0.5154 & 0.9778 & 0.5154 \\
0 & 0.5154 & 2.0088 & 0.5154 & 0.5154 & 0.5154 & 0.9778 \\
0 & 0.5154 & 0.5154 & 2.0088 & 0.5154 & 0.5154 & 0.5154 \\
0.9778 & 0.5154 & 0.5154 & 0.9778 & 2.0088 & 0.9778 & 0.9778 \\
0.5154 & 0.9778 & 0.5154 & 0.9778 & 0.9778 & 0.9778 & 0.9778 \\
\end{array}
\]

which gives currently the best known lattice packing-covering in dimension 6 with packing-covering constant \( Q^6_{E_6} \) 1.411081. In the next section we will examine these new PQFs in greater detail.

### 11.4 Beautification and a Unified View

Although we found an answer to Ryshkov’s question, these results are not fully satisfying. We want to know the exact lattices and prove rigorously that they have a good covering density and that they are locally optimal. Even more important, we want to know an interpretation of why these lattice coverings are good. To accomplish this we collect some more data.

The automorphism group of $\text{Del}(Q^6_{E_6})$ has order 3840 and the one of $\text{Del}(Q^6_{E_6}^c)$ has order 240. With the knowledge of the groups we were able to compute the extreme rays of both secondary cones [DV04]. The secondary cone $C_1 = (\text{Del}(Q^6_{E_6}))$ has 7,145;429 and the cone $C_2 = (\text{Del}(Q^6_{E_6}^c))$ has 2,257;616 extreme rays. Both contain an extreme ray associated to the lattice $E_6$ given for example by the PQF

\[
Q_{E_6} = \begin{array}{cccccc}
0 & 4 & 1 & 2 & 2 & 1 \\
1 & 4 & 2 & 2 & 2 & 1 \\
2 & 2 & 4 & 1 & 1 & 2 \\
2 & 2 & 1 & 4 & 1 & 2 \\
1 & 2 & 1 & 1 & 4 & 2 \\
1 & 1 & 2 & 2 & 2 & 4 \\
\end{array}
\]

After transforming $Q^6_{E_6}$ and $Q^6_{E_6}^c$ by integral unimodular transformations we can assume that the Delone triangulations of the two PQFs are refinements of the Delone subdivision $\text{Del}(Q_{E_6})$. This Delone subdivision was investigated in different contexts (see [Wor87], [CS91], [MP95] and [Bar92]). We briefly review the main results:

**Proposition 11.4.** In the star of the origin are 720 full-dimensional 6-dimensional Delone polytopes, and the automorphism group of $Q_{E_6}$ acts transitively on these full-dimensional polytopes. Each polytope is the convex hull of three regular triangles lying in three pairwise orthogonal affine planes. Each polytope has 9 vertices, 27 facets, and three different triangulations, where each triangulation consists of nine 6-dimensional simplices. The covering density is \( (Q_{E_6}) = \frac{9}{6} 2 \approx 1.62071 \).

**Proof:** Except for the possible refining triangulations, all this data is well-known, see for example [CS91], Summary for $E_6$.

To describe the triangulations we introduce coordinates. A Delone polytope of $Q_{E_6}$ is similar to the polytope $P = \text{conv} f_1; u_1; u_2; v_1; v_2; w_1; w_2; g$ where $u_1 = e_1, u_2 = \frac{1}{2}e_1 + \frac{p_{1/2}}{2} e_2, v_1 = \frac{1}{2}e_1 + \frac{3}{2} e_2, v_2 = \frac{1}{2}e_3 + \frac{3}{2} e_4, w_1 = \frac{1}{2}e_3 + \frac{3}{2} e_4, w_2 = \frac{1}{2}e_3 + \frac{3}{2} e_6, w_3 = \frac{1}{2}e_5 + \frac{3}{2} e_6$. The three possible triangulations are given by the set of nine 6-dimensional simplices

\[
\begin{align*}
T_u &= \text{conv vert} P n f v z; w z g : z 0 2 1 f l! ; T g \\
T_v &= \text{conv vert} P n f v z; w z g : z 0 2 1 f l! ; T g \\
T_w &= \text{conv vert} P n f v z; w z g : z 0 2 1 f l! ; T g \\
\end{align*}
\]
To finish the proof one has to show that these sets indeed define triangulations and that they are the only possible triangulations. This can be done by a straightforward computation using the facts that the minimal affine dependent subsets of $\text{vert} \mathcal{P}$ are

$$\text{conv} \text{vert} \mathcal{P} n \text{fu}_2 ; \text{fu}_2 ; w_2 g$$

that the facets of $\mathcal{P}$ are $\text{conv} \text{vert} \mathcal{T} \text{nf} \cdot 40 \cdot ! T g$, and by applying the following proposition.

**Proposition 11.5.** ([Ram97], Prop. 2.2) Let $A \in \mathbb{R}^d$ be a finite point set, and let $T$ be a set of $d$-dimensional simplices with vertices in $A$. The set $T$ defines a triangulation of the polytope $\text{conv} A$ if and only if the following two conditions hold:

1. For all $S \subseteq \mathbb{R}^d$ there exists a minimal affine dependency $P_{a_{2A}} a = 0$ with $P_{a_{2A}} a = 0$ so that $a > 0 g S$ and $a < 0 g S^0$.
2. For all $S \subseteq T$ and for every $(d - 1)$-dimensional facet $F$ of $S$ there exists either a $(d - 1)$-dimensional facet $F^0$ of $\text{conv} A$ with $F^0$ or there exists another simplex $S' \subseteq T$ not having $F$ as a facet.

Using this information we are able to prove that the PQF $Q_{E_6}^{(1)}$ is closely related to $Q_{E_6}$.

**Theorem 11.6.** The PQF $Q_{E_6}^{(1)}$ gives the least dense lattice covering among all PQFs whose Delone subdivision is a refinement of the Delone subdivision $D \ \text{del} (Q_{E_6})$.

**Proof.** Our proof is computational and uses a branch and cut method. We have to show that all secondary cones of a Delone triangulation refining $D \ \text{del} (Q_{E_6})$ do not contain a PQF with covering density less than $Q_{E_6}^{(1)}$. There are 40 full-dimensional Delone polytopes of $Q_{E_6}$ which cannot be transformed into each other by translations or by the map $x \ x$. Since each of these Delone polytopes has 3 possible triangulations, the number of all periodic triangulations refining $D \ \text{del} (Q_{E_6})$ is $3^{40}$. It is not apriori clear how to distinguish between Delone and non-Delone triangulations, and it is not possible to generate all $3^{40}$ triangulations. We choose a backtracking approach instead.

We arrange partial triangulations in a tree. On every level one of the 40 Delone polytopes is triangulated so that we have 3$^n$ nodes on the $n$-th level. For every node $N$ we define the value

$$N = \max \ \text{det} (Q) : Q \ 2 S^6_0, \text{BR}_L (Q) \ 0 \text{ for all simplices } L \text{ of partial triangulation } N$$

Obviously, $N$ is a lower bound for the covering density of any PQF whose Delone subdivision refines the partial triangulation $N$. We can compute a lower bound of this value by solving a determinant maximization problem similar to the one in Section 8.3. Note that this can be done rigorously using rational arithmetic only if we proceed as described in Section 8.3 If the lower bound is larger than 2.464802, we can cut the tree at this node, since the covering density of $Q_{E_6}^{(1)}$ is less than 2.464801 (see Theorem 11.3).

This algorithm visits exactly 432 nodes of depth 40. One of these triangulations equals $D \ \text{del} (Q_{E_6}^{(1)})$. All the others are equivalent to $D \ \text{del} (Q_{E_6}^{(1)})$ because the automorphism group of $D \ \text{del} (Q_{E_6}^{(1)})$, which has order 240, is a subgroup of $\text{Aut} (Q_{E_6})$ and the order of $\text{Aut} (Q_{E_6})$ equals 103680 = 432 x 240.

This computational proof takes about two weeks on a 2GHz Intel Pentium computer. The source code $e6d.cc$ is available from our web page [SV05] as part of the package rmd.
The knowledge of the automorphism groups of \( \text{Del}(Q_{6}^{c1}) \) and \( \text{Del}(Q_{6}^{c2}) \) also enables us to give a unified view on both lattices. We have

\[
\text{Aut}(\text{Del}(Q_{6}^{c1})) \quad \text{Aut}(\text{Del}(Q_{6}^{c2})) \quad \text{Aut}(Q_{6}):
\]

The automorphism group \( \text{Aut}(\text{Del}(Q_{6}^{c2})) \) turns out to be the subgroup of \( \text{Aut}(Q_{6}) \) stabilizing the minimal vectors \( e_{1} \), and \( \text{Aut}(\text{Del}(Q_{6}^{c1})) \) is the intersection of the two subgroups of \( \text{Aut}(Q_{6}) \) stabilizing the minimal vectors \( e_{1} \) and \( e_{2} \) respectively.

The subspace \( I_{1} \) of all quadratic forms invariant under the group \( \text{Aut}(\text{Del}(Q_{6}^{c2})) \) is spanned by the PQFs \( Q_{E_{6}} \) and \( R_{1} \) (see below). At the same time, \( I_{1} \backslash C_{1} \) is a cone with extreme rays \( Q_{E_{6}} ; R_{1} \). By Proposition 2, \( Q_{6}^{c2} \) has to lie in \( \text{cone} Q_{E_{6}} ; R_{1} \). The subspace \( I_{2} \) of all quadratic forms invariant under the group \( \text{Aut}(\text{Del}(Q_{6}^{c1})) \) is four-dimensional. The cone \( I_{2} \backslash C_{2} \) has six extreme rays \( Q_{E_{6}} ; R_{2} ; \ldots ; R_{6} \), where

\[
\begin{align*}
R_{1} & = \begin{bmatrix} 0 & 12 & 3 & 6 & 6 & 3 & 3 \\ 3 & 7 & 4 & 4 & 3 & 2 & 0 \\ 6 & 4 & 8 & 8 & 1 & 4 & 3 \\ 3 & 3 & 1 & 1 & 7 & 3 & 4 \\ 3 & 2 & 4 & 4 & 3 & 7 & 1 \end{bmatrix} \\
R_{2} & = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 2 & 0 & 4 & 2 & 2 & 3 \\ 0 & 2 & 0 & 4 & 2 & 2 & 3 \\ 0 & 3 & 2 & 2 & 5 & 3 & 4 \\ 0 & 1 & 2 & 2 & 3 & 5 \end{bmatrix} \\
R_{3} & = \begin{bmatrix} 1 & 6 & 4 & 4 & 0 & 2 \\ 4 & 11 & 6 & 6 & 5 & 3 & 4 \\ 4 & 6 & 8 & 3 & 3 & 4 & 4 \\ 0 & 5 & 3 & 3 & 7 & 4 & 4 \\ 2 & 3 & 4 & 4 & 4 & 7 \end{bmatrix} \\
R_{4} & = \begin{bmatrix} 0 & 3 & 2 & 2 & 0 & 1 \\ 2 & 3 & 2 & 2 & 1 & 1 & 0 \\ 2 & 2 & 4 & 4 & 2 & 4 & 6 \\ 0 & 1 & 1 & 1 & 3 & 2 & 0 \\ 1 & 1 & 2 & 2 & 2 & 4 \end{bmatrix} \\
R_{5} & = \begin{bmatrix} 7 & 3 & 4 & 4 & 1 & 2 \\ 3 & 17 & 8 & 8 & 9 & 4 & 3 \\ 4 & 8 & 3 & 12 & 5 & 6 & 3 \\ 4 & 8 & 3 & 12 & 5 & 6 & 3 \\ 1 & 9 & 5 & 5 & 13 & 7 & 4 \\ 2 & 4 & 6 & 6 & 7 & 12 & 3 \end{bmatrix} \\
R_{6} & = \begin{bmatrix} 9 & 6 & 6 & 6 & 0 & 3 & 3 \\ 6 & 9 & 6 & 6 & 3 & 3 & 3 \\ 6 & 8 & 4 & 2 & 4 & 4 & 4 \\ 0 & 3 & 2 & 2 & 5 & 4 & 4 \\ 3 & 3 & 4 & 4 & 3 & 6 \end{bmatrix}
\end{align*}
\]

Note that \( R_{2} \) lies in \( I_{1} \). Altogether, this yields the “picture” in dimension 21 given in Figure 5.

Let us finally try to find the exact coordinates of the PQFs. This is easy for \( Q_{6}^{c2} \). We know that we can scale \( Q_{6}^{c2} \) so that \( Q_{6}^{c2} = Q_{E_{6}} + xR_{1} \), for some \( x \in \mathbb{R} \). Now, the exact finding of \( x \) boils down to finding roots of an univariate polynomial: we have to minimize the function \( \tau(x) = (Q_{E_{6}} + xR_{1})^{1} = \text{det}(Q_{E_{6}} + xR_{1}) \) where we know, because of the approximate solution, that \( Q_{E_{6}} + xR_{1} \) is a polynomial for all points in a sufficiently small neighborhood of the exact \( x \). This leads to the Ansatz

\[
Q_{6}^{c2} = Q_{E_{6}} + \frac{P}{Q} + \frac{1}{88} R_{1}:
\]

Now we can use the tools we introduced in Section 2 to prove rigorously that this Ansatz works.

**Theorem 11.7.** The PQF \( Q_{6}^{c2} \) gives a locally optimal lattice covering. Its covering density is

\[
\left( Q_{6}^{c2} \right) = \frac{P}{1124895337698} = \frac{1057}{3543122} = \frac{1}{6} 2 \times 66121650:
\]

**Proof.** Our proof is again computational. We provide the MAGMA program check_q6c2.m at the arXiv.org e-print archive. To access it, download the source files for the paper math.MG/0403272. Since it uses rational arithmetic only, the proof is rigorous.

Let us describe the steps. First we compute the Delone subdivision of \( Q_{6}^{c2} \). We compute the Delone subdivisions of the three PQFs \( Q_{1} = \frac{9}{10}Q_{E_{6}} + \frac{3}{10}R_{1} \), \( Q_{2} = \frac{11}{10}Q_{E_{6}} + \frac{3}{10}R_{1} \), and \( Q_{3} = \frac{11}{10}Q_{E_{6}} + \frac{5}{10}R_{1} \). Then we check that they coincide and that it turns out to be a triangulation. Then we show that \( Q_{6}^{c2} \) 2
convfQ_1; Q_2; Q_3 g so that D e l(Q^{c_2}_6) = D e l(Q_1). Now we can compute the circumradii of all the Delone simplices by the formula (3) in proof of Proposition 7.1. This gives the value (Q^{c_2}_6). Finally we prove that Q^{c_2}_6 gives a locally optimal lattice covering using the criterion of Proposition 9.9. We compute the gradients g_L for all simplices L \in D e l(Q^{c_2}_6) achieving maximum circumradius. Summing them up yields a multiple of (Q^{c_2}_6)^1.

This computational proof takes about one minute on a 2GHz Intel Pentium computer.

What is the general pattern behind the beautification process? Let Q be a locally optimal lattice covering with Delone triangulation D. We use the symmetry of D to find the subspace in which Q lies. This reduces the number of involved variables. The simplices of the Delone triangulation which have circumradius 1 give equality constraints. Then we maximize the determinant of the quadratic forms lying in the subspace subject to the equality constraints. For this optimization problem, which involves only algebraic equations, we can use Gröbner basis techniques.

Unfortunately, we were not able to solve the corresponding algebraic equations for Q^{c_1}_6 so we have to be satisfied with an approximation.

**Theorem 11.8.** The covering density of the PQF Q^{c_1}_6 is at most \(2 \neq 64801\).

**Proof.** The covering density of the PQF Q^{c_1}_6 + xR_2 + yR_3 + zR_4 with \(x = 0 \neq 5266328480099\), \(y = 0 \neq 3288474061498\), \(z = 0 \neq 3827491241153\) is smaller than \(2 \neq 64801\). For a computational proof of this fact we provide the MAGMA program check_q6c1.m, available from the source files of the paper math.MG/0403272 at the arXiv.org e-print archive. The steps are similar to the first steps of the proof of Theorem 11.7.

On the basis of Theorem 11.6 and our extensive computational experiments we make the following conjecture.

**Conjecture 11.9.** The PQF Q^{c_1}_6 provides the unique least dense lattice covering in dimension 6.
Using a similar and more successful beautification process for $Q_6^{pc}$, we make the Ansatz

$$Q_6^{pc} = Q_{E_6} + \frac{P^{798}}{79} \cdot 18 \cdot R_1.$$ 

**Theorem 11.10.** $Q_6^{pc}$ is a locally optimal solution to the lattice packing-covering problem, lying in the interior of its secondary cone. Its lattice packing covering constant is

$$\langle Q_6^{pc} \rangle = 2 \cdot \frac{798}{79} \cdot 56 = \approx 11081242:$$

**Proof.** This is similar to the proof of Theorem 11.7. We provide the MAGMA program `check_q6pc.m`, available from the source files of the paper math.MG/0403272 at the arXiv.org e-print archive. 

### 11.5 Dimension 7

After analyzing the 6-dimensional case, we got a feeling of where we have to search for good 7-dimensional lattice coverings. We took $Q_{E_7}$, and a lattice vector which is a longest vector of the shortest vectors in the cosets $Z^d = 2Z^d$. We computed the stabilizer group of this vector and the invariant subspace of this group. By perturbing $Q_{E_7}$ in this subspace randomly, we found a PQF whose Delone subdivision is a triangulation. We solved the determinant maximization problem of Section 8.1 which belongs to this Delone triangulation and found the PQF

$$Q_7 = \begin{pmatrix}
0 & 12 & 1 & 1 & 1 & 1 & 1 & 5 & 1 \\
1 & 12 & 1 & 1 & 1 & 1 & 5 & \circ & \circ \\
1 & 1 & 12 & 1 & 1 & 1 & 5 & \circ & \circ \\
1 & 1 & 1 & 12 & 1 & 1 & 5 & \circ & \circ \\
1 & 1 & 1 & 1 & 12 & 1 & 5 & \circ & \circ \\
1 & 1 & 1 & 1 & 1 & 12 & 6 & \circ & \circ \\
5 & 5 & 5 & 5 & 5 & 5 & 6 & 14
\end{pmatrix}$$

We are quite surprised that this PQF has rational entries.

**Theorem 11.11.** $Q_7$ is a locally optimal solution to the lattice covering problem, lying in the interior of its secondary cone. Its inhomogeneous minimum is $\delta = \frac{15}{2}$, its determinant is $\det Q_7 = 2 \cdot 11$, so that

$$\langle Q_7 \rangle = 2 \cdot 900024.$$ 

**Proof.** Again, this is similar to the proof of Theorem 11.7. We provide the MAGMA program `check_q7c.m`, available from the source files of the paper math.MG/0403272 at the arXiv.org e-print archive. 

### Acknowledgment

We wish to thank Mathieu Dutour for the simplified formulation of the optimization problem in Section 8.2, Jörg Rambau for pointing out the reference to Proposition 11.5, Francisco Santos for helpful discussions, and Tyrrell B. McAllister for improving the grammar of our text. In particular we wish to thank one of the anonymous referees for his detailed report with many helpful comments and suggestions on a previous version.
