Abstract

Ubiquitination plays important roles in plant growth and development. Whereas ubiquitin-dependent protein degradation and modulation in the cytoplasm and nucleus are well established in plants, ubiquitination events mediated by E3 ubiquitin ligases at the plasma membrane are largely unknown. Here, it is demonstrated that the suppressor of premature senescence and cell death SENESCENCE-ASSOCIATED UBIQUITIN LIGASE 1 (SAUL1), a plant U-box armadillo repeat (PUB-ARM) E3 ubiquitin ligase, localizes at the plasma membrane. Among the members of the PUB-ARM protein family, this localization is unique to SAUL1 and its two closest homologues. A novel armadillo repeat domain was identified at the SAUL1 C-terminus that directs specific association with the plasma membrane and is crucial for SAUL1 function in vivo. The data suggest that a small subgroup of PUB-ARM proteins including SAUL1 have functions at the plasma membrane probably by modifying target proteins by ubiquitination.

Key words: Armadillo repeat, ARM repeat, E3 ubiquitin ligase, plasma membrane, SAUL1, U-box.

Introduction

The regulation of many cellular processes as important as transcription and cell cycle control, and a plethora of physiological responses require specific degradation of key regulatory proteins. In most cases, the ubiquitin–26S proteasome pathway is important for regulated proteolysis by mediating polyubiquitination and thus degradation of target proteins. This pathway comprises ubiquitin-activating enzymes (E1s), ubiquitin-conjugating enzymes (E2s), ubiquitin ligases (E3s), the proteasome complex, and de-ubiquitinating enzymes (DUBs) (Kerscher et al., 2006; Vierstra, 2009). This pathway also governs monoubiquitination of target proteins to modulate protein functions in processes such as endocytosis and internalization of plasma membrane proteins (Sigismund et al., 2004). Binding of target proteins prior to ubiquitination occurs via E3 ubiquitin ligases, thus defining the specificity of the ubiquitin–26S proteasome pathway.

In various eukaryotes, large numbers of E3 ubiquitin ligases are found. In the model plant Arabidopsis thaliana probably >1300 E3s exist that can be grouped into four main types: HECT, RING, U-box, and cullin-RING ligases (including SCF E3s). Together, RING-containing and SCF E3s/F-box proteins account for the majority of E3 ligases and cover essential functions in plant biology such as organ morphogenesis and hormone signalling (Schwechheimer and Calderon Villalobos, 2004; Stone and Callis, 2007; Santner and Estelle, 2009; Vierstra, 2009). In contrast, the plant U-box (PUB) protein family representing the most recently identified type of E3 ligases contains only 64 predicted members (Azevedo et al., 2001; Wiborg et al., 2008). This protein family is characterized by the highly conserved U-box originally described for the yeast UFD2 protein (Koegl et al., 1999). The U-box motif consists of ~70 amino acids and resembles a modified RING-domain that lacks crucial residues for metal binding (Aravind and Koonin, 2000). It has been demonstrated that the U-box is essential for activity of these ubiquitin ligases (Hatakeyama et al., 2001; Zeng et al., 2004; Gonzalez-Lamothe et al., 2006).
In addition to the U-box, most PUB proteins carry tandem armadillo (ARM) repeats and thus form the subgroup of PUB-ARM proteins (Mudgil et al., 2004). The ARM nomenclature originates from a motif of ~42 amino acids discovered in the gene product of the Drosophila segment polarity gene armadillo (Nusslein-Volhard and Wieschaus, 1980; Riggleman et al., 1989). ARM repeats give rise to conserved protein structures. One such repeat consists of three \( \alpha \)-helices, and multiple ARM repeats interact and form interfaces for protein–protein interactions (Huber et al., 1997; Conti and Kuriyan, 2000; Coates, 2003). ARM repeat proteins serve diverse functions in eukaryotic cells. The Saccharomyces cerevisiae protein Vac8 is a vacuolar membrane protein involved in vacuole inheritance and vacuolar membrane fusion (Pan and Goldfarb, 1998; Fleckenstein et al., 1998). Importin-\( \alpha \) and its homologues function in the transport of proteins into the nucleus in conjunction with importin-\( \beta \) and in inhibition of mitotic spindle formation (Gorlich and Kutay, 1999; Gruss et al., 2001). Recently, it has been shown that a small fraction of importin-\( \alpha \) was also detectable in membrane fractions (Hachet et al., 2004). The best-studied ARM protein, \( \beta \)-catenin, has essential roles in cell adhesion through maintenance of cell-cell adherens junctions and in Wnt signal transduction as a transcriptional coactivator. At the cell periphery, \( \beta \)-catenin interacts with the cytoplasmic end of cadherins. Wnt signalling blocks degradation of \( \beta \)-catenin in the cytoplasm via a protein complex including adenomatous polyposis coli (APC) and supports translocation of \( \beta \)-catenin into the nucleus where it interacts with transcription factors (Zhurinsky et al., 2000).

During a plant’s life cycle, PUB-ARM proteins play critical roles in diverse processes. The potato PHOR1 (PHOTOPERIOD RESPONSIVE 1) protein functions in light and gibberellin signalling (Amador et al., 2001). The related protein ARC1 (ARM repeat containing 1) from Brassica is involved in the self-incompatibility response (Stone et al., 2003). In Arabidopsis, PUB22 and PUB23 have been implicated in drought signalling (Cho et al., 2008). In addition, a number of PUB-ARM proteins from different plant species have functions in the pathogen response, including tobacco ACRE276 (Avr/Cf-9 Rapidly elicited 276) and CMPG1, as well as Arabidopsis PUB17, PUB22, PUB23, and PUB24 (Gonzalez-Lamothe et al., 2006; Yang et al., 2006; Trujillo et al., 2008). The rice SPL11 (spotted leaf 11) and the Arabidopsis SAUL1 (SENESCENCE-ASSOCIATED UBIQUITIN LIGASE 1) protein have regulatory functions in cell death/senescence control (Zeng et al., 2004; Raab et al., 2009). To this end, PUB-ARM proteins have been localized in the nucleus, in the cytosol, and in proteasome structures at the endoplasmic reticulum (ER) (Amador et al., 2001; Stone et al., 2003; Cho et al., 2008; Samuel et al., 2008).

In this study, properties of the PUB-ARM E3 ubiquitin ligase SAUL1 that has been described as a suppressor of premature senescence in Arabidopsis (Raab et al., 2009) were further investigated. Protoplast transformation and confocal laser scanning microscopy were applied to study the localization of fusion proteins consisting of different fluorescent proteins and full-length SAUL1 or mutant SAUL1 with different deletions. It could be shown that SAUL1 is localized at the plasma membrane, and five ARM repeats were identified at its C-terminal end that comprise a domain which is crucial for this localization. Furthermore, this protein domain was sufficient to drive plasma membrane association of PUB-ARM proteins that usually reside in the cytoplasm. Impaired plasma membrane association abolished SAUL1 function in vivo. The data suggest that SAUL1 is involved in ubiquitination of proteins at the plasma membrane.

Materials and methods

Cloning of DNA constructs

For generation of fusion proteins between full-length PUB-ARM proteins or SAUL1 carrying terminal truncations and green fluorescent protein (GFP), yellow fluorescent protein (YFP), or haemagglutinin (HA), the respective fragments were amplified from cDNA or genomic DNA using the primer pairs listed in Supplementary Table S1 available at JXB online. The Umart1 open reading frame was amplified using primers 5′-CACCAAGCGGTGTCGTCTCTTC-3′ and 5′-GGATCTTGGGTGACCTCGCTGC-3′ from yeast expression vectors carrying Umart1 (Wahl et al., 2010). For generation of N- or C-terminal deletions of the SAUL1 protein, fragments were generated by PCR using the primers depicted in Supplementary Table S2. For deletion of internal ARM repeats, a two-step PCR mutagenesis was performed generating two DNA fragments harbouring the up- and downstream sequences of the corresponding ARM repeat in a first PCR. The primers used in this PCR introduced overlapping DNA sequences over-spanning the corresponding ARM repeat. By using these templates as templates for a second PCR, DNA fragments lacking the ARM repeats 7–8 or 9 were generated. The amplified fragments were cloned into pENTR/D-TOPOR (Invitrogen, Karlsruhe, Germany), sequenced, and recombined into destination vectors pEARLEYGATE104 and pEARLEYGATE201 (Earley et al., 2006) for the YFP and HA constructs, respectively, pMDC43 for fusion of GFP to the N-terminus (Curtis and Grossniklaus, 2003), pK7FWG2.0 for fusion of GFP to the C-terminus (Karimi et al., 2002), or pH7RGW2.0 for the Umart1-RFP construct (Karimi et al., 2002). For generation of the CaMV35S-promoter::PUB27-SAUL1ARM7–11-GFP chimeric constructs, a SAUL1ARM7–11 fragment carrying BsmHI restriction sites at both ends was amplified using primers 5′-CAGGATCCATTAGCAACACAGTCCAG-3′ and 5′-CTTGATGCTCGGATGGTTGGGAATATAC-3′. The PCR fragment was subcloned into the vector pJET 1.2/blunt (Fermentas, St Leon-Rot, Germany), sequenced, and cloned into the expression vector CaMV35S-promoter::PUB27-GFP via the introduced BsmHI sites. The generated plasmids were used for transformation of Arabidopsis mesophyll protoplasts, Nicotiana benthamiana leaves, and Arabidopsis plants, respectively.

Protoplast isolation and transformation

Protoplasts were isolated from fully expanded leaves of 3- to 4-week-old Arabidopsis plants grown on soil. Leaves were roughened using sandpaper, transferred to protoplasting buffer (500 mM sorbitol, 1 mM CaCl\(_2\), 0.03% pectolyase Y23, 0.75% cellulose YC, and 10 mM MES-KOH, pH 5.6–6.0), and incubated in the dark at 22°C for 1.5 h with gentle agitation (60–75 rpm). Protoplasts were separated from undigested material by filtration through a 50 µm nylon mesh and sedimented by centrifugation for

**Cloning of DNA constructs**

For generation of fusion proteins between full-length PUB-ARM proteins or SAUL1 carrying terminal truncations and green fluorescent protein (GFP), yellow fluorescent protein (YFP), or haemagglutinin (HA), the respective fragments were amplified from cDNA or genomic DNA using the primer pairs listed in Supplementary Table S1 available at JXB online. The Umart1 open reading frame was amplified using primers 5′-CACCAAGCGGTGTCGTCTCTTC-3′ and 5′-GGATCTTGGGTGACCTCGCTGC-3′ from yeast expression vectors carrying Umart1 (Wahl et al., 2010). For generation of N- or C-terminal deletions of the SAUL1 protein, fragments were generated by PCR using the primers depicted in Supplementary Table S2. For deletion of internal ARM repeats, a two-step PCR mutagenesis was performed generating two DNA fragments harbouring the up- and downstream sequences of the corresponding ARM repeat in a first PCR. The primers used in this PCR introduced overlapping DNA sequences over-spanning the corresponding ARM repeat. By using these templates as templates for a second PCR, DNA fragments lacking the ARM repeats 7–8 or 9 were generated. The amplified fragments were cloned into pENTR/D-TOPO for fusion of GFP to the C-terminus (Karimi et al., 2002), or pH7RGW2.0 for the Umart1-RFP construct (Karimi et al., 2002). For generation of the CaMV35S-promoter::PUB27-SAUL1ARM7–11-GFP chimeric constructs, a SAUL1ARM7–11 fragment carrying BsmHI restriction sites at both ends was amplified using primers 5′-CAGGATCCATTAGCAACACAGTCCAG-3′ and 5′-CTTGATGCTCGGATGGTTGGGAATATAC-3′. The PCR fragment was subcloned into the vector pJET 1.2/blunt (Fermentas, St Leon-Rot, Germany), sequenced, and cloned into the expression vector CaMV35S-promoter::PUB27-GFP via the introduced BsmHI sites. The generated plasmids were used for transformation of Arabidopsis mesophyll protoplasts, Nicotiana benthamiana leaves, and Arabidopsis plants, respectively.
8 min at 100 g. The pellet was resuspended in MaMg buffer (400 mM sorbitol, 15 mM MgCl₂, 5 mM MES-KOH, pH 5.6). Protoplast transformation was performed essentially as previously described (Abel and Theologis, 1994). Transformed protoplasts were transferred into small Petri dishes and incubated for 24 h in the dark at 22 °C prior to analysis by confocal laser scanning microscopy.

**Stable and transient plant transformation**

The generated plasmids CaMV35S-promoter:YFP-SAUL1 and CaMV35S-promoter:HA-SAUL1 were used for stable transformation of Arabidopsis wild-type (Columbia) plants by floral dip (Clough and Bent, 1998; Raab et al., 2009). The plasmids CaMV35S-promoter:SAUL1:ARM₂-;element-GFP and CaMV35S-promoter:SAUL1-GFP were used to transform saul-1 mutants. Transformants were obtained by BASTA selection. For transient transformation of \textit{N. benthamiana} leaves, \textit{Agrobacterium tumefaciens} strain CS51 (Deblaere et al., 1985) harbouring the \textit{P₅₂₀:yfp::GFP-Saul1} construct was grown at 29 °C in LB supplemented with 50 µg ml⁻¹ kanamycin to the stationary phase. Bacteria were sedimented by centrifugation at 5000 g for 15 min at room temperature and resuspended in infiltration buffer (10 mM MgCl₂, 10 mM MES, KOH pH 5.7). Cells were infiltrated into the abaxial air spaces of 2- to 4-week-old \textit{N. benthamiana} plants. GFP-Saul1 fluorescence was monitored by confocal laser scanning microscopy 24 h post-infiltration.

**Confocal laser scanning microscopy**

Fluorescence of YFP fusions, GFP fusions, and UmSrt1-red fluorescent protein (RFP) was monitored by confocal laser scanning microscopy (Leica TCS SP II; Leica Microsystems, Wetzlar, Germany) using 488 nm (GFP), 514 nm (YFP), and 543 nm (RFP) laser light for excitation. Detection windows ranged from 497 nm to 527 nm for GFP, from 525 nm to 575 nm for YFP, and from 570 nm to 625 nm for RFP.

**Generation of anti-Saul1 antibodies and western blot analysis**

Purified 6×His-SAUL1 protein (Raab et al., 2009) was used for immunization of rabbits, performed by Dr Pineda Antibody Service. For affinity purification of anti-Saul1 antibodies, nitrocellulose filters soaked with 1 mg ml⁻¹ MBP-SAUL1 fusion peptide (Raab et al., 2009) and blocked with skim milk-containing buffer (50 mM TRIS, pH 7.5, 150 mM NaCl, 0.1% Triton X-100, 1% skim milk powder) were incubated in raw antiserum for at least 60 min at 4 °C, washed, and bound antibodies were released as described (Sauer and Stadler, 1993).

For total membrane preparation Arabidopsis plant material was ground in liquid nitrogen and grinding buffer containing 20 mM HEPES, pH 7.5, 100 mM NaCl, 5 mM MgCl₂, 1 mM dithiothreitol (DTT), and protease inhibitor mix (Complete Mini tablets, EDTA-free, Roche) was added. Samples were incubated on ice for 10 min and centrifuged twice for 10 min at 3500 g and 4 °C. The supernatant was centrifuged at 100 000 g and 4 °C for 1 h to separate soluble protein and total membrane fractions. Protein samples were resolved on 10% SDS-PAGE, followed by gel-blot analysis using purified anti-Saul1 antibodies.

**Results**

The PUB-ARM E3 ubiquitin ligase SAUL1 is localized at the plasma membrane.

Recent results obtained by monitoring gene expression changes during premature senescence in \textit{saul} mutants suggested that the E3 ubiquitin ligase SAUL1 acts upstream of these transcriptional changes (Raab et al., 2009). The aim of this study was therefore to identify the compartment harbouring SAUL1 activity. Soluble proteins and total membrane fractions were isolated, specific anti-SAUL1 antibodies were established, and western blot analyses of SAUL1 protein were performed in wild-type and \textit{CaMV35S:HA-SAUL1} plants. Whereas SAUL1 protein could not be detected in wild-type samples, HA-SAUL1 protein was present in membrane fractions of \textit{CaMV35S:HA-SAUL1} plants (Fig. 1A). To define the membrane with which SAUL1 is associated, \textit{Arabidopsis} leaf protoplasts were transiently transformed with \textit{CaMV35S-promoter:YFP-SAUL1} or \textit{CaMV35S-promoter:GFP-SAUL1} fusion constructs. Consecutively, confocal laser scanning microscopy was used and fluorescence signals were detected at the plasma membrane (Fig. 1B-D). To prove plasma membrane association of SAUL1, the plasma membrane sugar transport protein UmSrt1 from the phytopathogenic fungus \textit{Ustilago maydis} fused to RFP was used for co-localization experiments (Wahl et al., 2010). Co-transformation of protoplasts with \textit{CaMV35S-promoter:GFP-SAUL1} and \textit{CaMV35S-promoter:UmSrt1-RFP} resulted in a match of green and red fluorescence, indicating that SAUL1 and the plasma membrane marker UmSrt1 were co-localized (Fig. 1D-G). Localization of SAUL1 at the plasma membrane was also confirmed in planta via transient expression of GFP-SAUL1 fusion proteins in \textit{N. benthamiana} leaves and stable expression of YFP-SAUL1 fusion proteins in \textit{A. thaliana} plants (Fig. 1H, I).

These results suggest that the plant U-box E3 ubiquitin ligase SAUL1 may have regulatory functions by modifying target proteins at the plasma membrane.

**Association with the plasma membrane is specific to a small subgroup of PUB-ARM proteins**

Localization of SAUL1 at the plasma membrane was independent of the position of the GFP tag (Figs 1B, D, 2A). To find out whether plasma membrane association is unique to SAUL1 among the \textit{Arabidopsis} PUB-ARM proteins, the aim was to determine the subcellular localization of at least one member of each subgroup of the PUB-ARM protein family (Mudgil et al., 2004). The closest homologue carrying one member of each subgroup of the PUB-ARM protein family resulted in a match of green and red fluorescence, indicating that SAUL1 and the plasma membrane marker UmSrt1 were co-localized (Fig. 1D-G). Localization of SAUL1 at the plasma membrane was also confirmed in planta via transient expression of GFP-SAUL1 fusion proteins in \textit{N. benthamiana} leaves and stable expression of YFP-SAUL1 fusion proteins in \textit{A. thaliana} plants (Fig. 1H, I).

These localization studies indicated that association with the plasma membrane was specific to members of only one subgroup of the PUB-ARM protein family, namely SAUL1, PUB43, and PUB42.
To investigate how SAUL1 is associated with the plasma membrane, DNA constructs were generated that lead to the expression of GFP fusion proteins containing different additions or deletions in Arabidopsis protoplasts (Fig. 3A). Transmembrane helices were not predicted to be present in SAUL1 (Schwacke et al., 2003). To exclude fully that SAUL1 is sequestered to the plasma membrane via the ER, ER retention signals were added, which would trap SAUL1 in the ER. After transient transformation of protoplasts with CaMV35S-promoter:SAUL1-GFP-HDEL constructs, GFP signals resembled the signals from GFP-SAUL1 fusion proteins, indicating that SAUL1 is not found in the ER at any time (Figs 1D, 3B).

Lipid modifications can generally mediate membrane association of proteins (Nambara and McCourt, 1999; Yalovsky et al., 1999; Schwacke et al., 2003). Because sites for these modifications most frequently reside in the N- or C-terminus, SAUL1–GFP fusion proteins carrying N- or C-terminal deletions were generated (Fig. 3A). After transient transformation of protoplasts with CaMV35S-promoter:GFP-SAUL1 and CaMV35S-promoter:Umsrt1–RFP DNA constructs, green and red fluorescence of GFP–SAUL1 (D) and UmSrt1–RFP (E) fusion proteins, respectively, was detected at the plasma membrane. Merging both pictures resulted in yellow colour, indicating co-localization of both proteins (F). (G) Transmission light picture of the protoplast from D and E. (H) Localization of GFP–SAUL1 fusion proteins in transiently transformed epidermal cells of Nicotiana benthamiana. Green fluorescence was observed at the plasma membrane. (I) Yellow fluorescence in transgenic CaMV35S-promoter:YFP–SAUL1 plants indicated localization of YFP–SAUL1 fusion proteins at the plasma membrane in planta. Autofluorescence of chlorophyll is shown in red in B, H, and I, or in blue in D–F. Scale bars represent 10 μm and 30 μm in H.

**Fig. 1.** Plasma membrane localization of SAUL1. (A) SAUL1 localization in membrane fractions. Soluble (S) and total membrane fractions (M) were isolated from wild-type and CaMV35S:HA-SAUL1 plants. Western blot analysis using anti-SAUL1 antibodies did not result in detection of SAUL1 protein in wild-type plants, but revealed the presence of the HA-tagged SAUL1 in total membrane fractions at the expected size in CaMV35S:HA-SAUL1 plants. (B) Localization of YFP–SAUL1 fusion proteins at the plasma membrane. Yellow fluorescence signals from Arabidopsis protoplasts transformed with CaMV35S-promoter:YFP–SAUL1 DNA constructs recorded by confocal laser scanning microscopy showed plasma membrane localization of YFP–SAUL1 fusion proteins. (C) Transmission light picture of the protoplast from B. (D–G) Co-localization of SAUL1 and the plasma membrane marker UmSrt1. After co-transformation of Arabidopsis protoplasts with CaMV35S-promoter:GFP-SAUL1 and CaMV35S-promoter:Umsrt1–RFP DNA constructs, green and red fluorescence of GFP–SAUL1 (D) and UmSrt1–RFP (E) fusion proteins, respectively, was detected at the plasma membrane. Merging both pictures resulted in yellow colour, indicating co-localization of both proteins (F). (G) Transmission light picture of the protoplast from D and E. (H) Localization of GFP–SAUL1 fusion proteins in transiently transformed epidermal cells of Nicotiana benthamiana. Green fluorescence was observed at the plasma membrane. (I) Yellow fluorescence in transgenic CaMV35S-promoter:YFP–SAUL1 plants indicated localization of YFP–SAUL1 fusion proteins at the plasma membrane in planta. Autofluorescence of chlorophyll is shown in red in B, H, and I, or in blue in D–F. Scale bars represent 10 μm and 30 μm in H.

Plasma membrane localization of SAUL1 does not require transmembrane helices or terminal lipid modifications

GFP signals resembled the signals from GFP-SAUL1 fusion proteins, indicating that SAUL1 is not found in the ER at any time (Figs 1D, 3B). Lipid modifications can generally mediate membrane association of proteins (Nambara and McCourt, 1999; Yalovsky et al., 1999; Schwacke et al., 2003). Because sites for these modifications most frequently reside in the N- or C-terminus, SAUL1–GFP fusion proteins carrying N- or C-terminal deletions were generated (Fig. 3A). After transient transformation of protoplasts with CaMV35S-promoter:GFP-SAUL1ΔAC constructs, fluorescence signals still indicated equal association of SAUL1AC–GFP with the plasma membrane (Fig. 3C). Additional deletion of the N-terminus in SAUL1ΔNAC–GFP fusion proteins also did...
not abolish plasma membrane association (Fig. 3D). However, the association of SAUL1ΔNΔC–GFP fusion proteins did not appear to be equally distributed, but occurred in patches, suggesting that the N-terminus is important for equal distribution. This was supported through transformation of protoplasts with CaMV35S-promoter:GFP-SAUL1ΔN constructs. Deletion of only the
N-terminus was sufficient to abolish equal distribution at the plasma membrane (Fig. 3E). In this context, it is important to mention that GFP-SAUL1 fusion proteins also featured patchy distribution in the plasma membrane in ~25% of protoplasts, probably due to masking of the N-terminus. This indicated that this part of the protein including the U-box is important for equal distribution of SAUL1 at the plasma membrane (Fig. 3F, G).

These findings suggest that SAUL1 is not integrated in the plasma membrane through membrane helices or attached to the plasma membrane via lipid modifications at the N- or C-terminus, respectively. Lipid modification sites have also not been predicted in the rest of the SAUL1 protein. In addition, the N-terminus carrying the U-box is important for equal distribution of SAUL1 at the plasma membrane.

**Plasma membrane localization of SAUL1 requires the C-terminal ARM repeat domain**

The SAUL1 protein contains 11 ARM repeats that may enable interactions with proteins in the plasma membrane. SAUL1 and PUB43 share a unique domain structure in contrast to all other PUB-ARM proteins in that they carry nearly twice the number of ARM repeats. Hence, they possess an elongated C-terminal half that is also found in PUB42 (Mudgil et al., 2004). Deletion constructs were generated to study the contribution of different ARM repeats for plasma membrane association (Fig. 4A). In a first step, the additional ARM repeats 7–11 in SAUL1 were deleted and SAUL1ΔARM7–11–GFP was expressed in Arabidopsis protoplasts. GFP signals indicated that the fusion proteins reside in intracellular structures other than the plasma membrane (Fig. 4B). To prove the loss of plasma membrane association, the plasma membrane sugar transport protein UmSrt1 from the phytopathogenic fungus U. maydis fused to RFP was used for co-localization experiments (Fig. 4C). Co-transformation of protoplasts with CaMV35S-promoter:SAUL1ΔARM7–11–GFP and CaMV35S-promoter:Umsrt1–RFP did not result in a match of green and red fluorescence signals, indicating that GFP–SAUL1ΔARM7–11 fusion proteins were not associated with the plasma membrane (Fig. 4D).

Consecutively, ARM repeats 7–11 were fused to GFP, thus deleting ARM repeats 1–6, and GFP-SAUL1ΔARM1–6 was expressed in Arabidopsis leaf protoplasts. Fluorescence signals were detected at the plasma membrane but, due to the absence of the N-terminus, in patches rather than equally distributed (Fig. 4E, cf. Fig. 3). Co-transformation of protoplasts with CaMV35S-promoter:GFP-SAUL1ΔARM1–6 and CaMV35S-promoter:Umsrt1–RFP led to a match of green and red fluorescence, indicating that GFP-SAUL1ΔARM1–6 and the plasma membrane marker UmSrt1 were co-localized at the plasma membrane (Fig. 4F, G).

To narrow down the ARM repeats that mediate plasma membrane association, ARM repeats 7–8 in SAUL1ΔARM7–8–GFP, ARM repeat 9 in GFP–SAUL1ΔARM9, and the last two C-terminal ARM repeats in GFP-SAUL1ΔARM10–11 fusion proteins were deleted (Fig. 4A). All three of these fusion proteins showed fluorescence signals comparable with GFP–SAUL1ΔARM7–11 fusion proteins in intracellular structures. These results led to the conclusion that all ARM repeats in this ARM repeat domain consisting of ARM repeats 7–11 are crucial for plasma membrane association of SAUL1 (Fig. 4H–J).

**Fig. 4.** Contribution of ARM repeats to localization of SAUL1 at the plasma membrane. (A) Schematic representation of constructs deleting ARM repeats of SAUL1. (B–D) Co-localization of SAUL1ΔARM7–11–GFP and UmSrt1–RFP. (B) GFP signals of SAUL1ΔARM7–11–GFP were detected in the cytoplasm of transformed protoplasts. (C) Red fluorescence indicated localization of UmSrt1–RFP at the plasma membrane. (D) Merging pictures from B and C did not result in overlapping GFP and RFP signals. (E–G) Co-localization of SAUL1ΔARM1–6–GFP and UmSrt1–RFP. (E) SAUL1ΔARM1–6–GFP fluorescence was observed in plasma membrane patches. (F) Red fluorescence indicated localization of UmSrt1–RFP at the plasma membrane. (G) Merging pictures from E and F did not result in overlapping GFP and RFP signals. (H–J) Co-localization of SAUL1ΔARM7–11–GFP and UmSrt1–RFP. (H) SAUL1ΔARM7–11–GFP fluorescence was observed in plasma membrane patches. (I) Red fluorescence indicated localization of UmSrt1–RFP at the plasma membrane. (J) Merging pictures from H and I led to yellow signals by overlapping GFP and RFP fluorescence, indicating localization of SAUL1ΔARM7–11–GFP at the plasma membrane. Deletion of single C-terminal ARM repeats resulted in loss of plasma membrane association in SAUL1ΔARM7–8–GFP (H), SAUL1ΔARM9–GFP (I), and SAUL1ΔARM10–11–GFP (J) fusion proteins. Autofluorescence of chlorophyll is shown in blue in B–G or in red in H–J. Scale bars represent 10 μm.
The C-terminal ARM repeat domain of SAUL1 mediates membrane association of the cytosolic PUB27 protein

With regard to the specific localization of SAUL1, PUB43, and PUB42 at the plasma membrane in contrast to all other PUB-ARM proteins tested, it was tempting to speculate that the elongated C-terminus could drive plasma membrane association of PUB-ARM proteins, which were normally localized in intracellular structures (Figs 2D, Supplementary S1 at JXB online). Therefore, CaMV35S-promoter:PUB27-SAUL1ARM7–11–GFP constructs were generated to equip PUB27 with the additional ARM repeat domain of SAUL1. After transformation of Arabidopsis leaf protoplasts, PUB27-SAUL1ARM7–11–GFP fusion proteins indeed appeared to associate with the plasma membrane as indicated by green fluorescence (Fig. 5A). To validate this observation, co-transformation experiments were performed using CaMV35S-promoter:PUB27-SAUL1ARM7–11–GFP and CaMV35S-promoter:UmSrt1–RFP constructs (Fig. 5). Red fluorescence of UmSrt1–RFP fusion proteins was detected at the plasma membrane as expected (Fig. 5B), and red and green fluorescence matched in co-transformed protoplasts (Fig. 5C).

Taken together, the findings indicate that the C-terminal ARM repeat domain consisting of up to six ARM repeats in addition to the common core ARM repeats are essential and sufficient for association of PUB-ARM proteins with the plasma membrane.

Plasma membrane association is crucial for SAUL1 function

To investigate whether localization of SAUL1 at the plasma membrane is important for its function in vivo, complementation analyses with respect to the saul1 mutant phenotype were performed. Stable transformation of saul1-1 mutant plants with the CaMV35S-promoter:SAUL1-GFP construct resulted in complementation of the early senescence phenotype of saul1-1 mutant seedlings (Fig. 6A–C). In contrast, transformation of saul1-1 mutants with the CaMV35S-promoter:SAUL1ARM7–11–GFP construct did not complement the phenotype (Fig. 6D). In these transgenic lines, localization of SAUL1–GFP at the plasma membrane and of SAUL1ARM7–11–GFP in the cytosol/nucleus was confirmed by confocal laser scanning microscopy (Fig. 6E, F). These data indicated that loss of plasma membrane association through deletion of the C-terminal ARM repeats in the SAUL1ARM7–11–GFP protein abolished SAUL1 function in vivo.

Discussion

The aim of this study was to identify the subcellular localization of the PUB-ARM E3 ubiquitin ligase SAUL1 that is a suppressor of premature senescence and cell death in order to gain further insight into the possible mode of action of SAUL1. SAUL1 was detected in total membrane fractions through western blot analysis using anti-SAUL1 antibodies. Interestingly, expression of SAUL1 fused to different fluorescent proteins in Arabidopsis leaf protoplasts revealed fluorescence signals at the plasma membrane (Fig. 1). To date, PUB-ARM proteins have been localized in the nucleus (StPHOR1, BnARC1, AtPUB9, AtPUB13), in the cytoplasm (StPHOR1, BnARC1, AtPUB13, AtPUB22, AtPUB23), and in proteasome structures at the ER (BnARC1) (Amador et al., 2001; Stone et al., 2003; Cho et al., 2008; Samuel et al., 2008). It was demonstrated that the association with the plasma membrane is specific for SAUL1 and its two closest homologues AtPUB43 and AtPUB42 (Fig. 2). This was supported by analysing the subcellular localization of 18 members of the PUB-ARM protein family that all localized to the cytoplasm and/or nucleus and not to the plasma membrane (Supplementary Fig. S1 at JXB online). Together with published PUB-ARM proteins localized in the cytoplasm and nucleus, the analysis of this collection covered almost two-thirds of the protein family and all branches of the phylogenetic tree published previously (Mudgil et al., 2004).

What is the structural determinant for plasma membrane association of SAUL1, AtPUB42, and AtPUB43? These three proteins differ from all other PUB-ARM proteins in that they carry an extended C-terminus containing an additional domain of up to six ARM repeats (Mudgil et al.,
proteins containing tandem ARM repeats in Arabidopsis (Coates, 2003; Mudgil et al., 2004). However, clear plasma membrane association has not been reported for any of these proteins yet. Instead, the Arabidopsis ARM repeat proteins IMPA-1, IMPA-4, ARABIDILLO-1, ARABIDILLO-2, ARIA, LFR, ARO1, and ABAPI have been shown to localize to the nucleus and/or the cytoplasm (Kim et al., 2004; Coates et al., 2006; Bhattacharjee et al., 2008; Gebert et al., 2008; Masuda et al., 2008; Wang et al., 2009). In a small fraction of analysed cells, plasma membrane association of Arabidopsis ARO1 in onion epidermis cells has been observed (Gebert et al., 2008). Taken together, these observations indicate a specific composition of ARM repeats in SAUL1 and its homologues, which mediates association with plasma membrane components.

The importance of tandem ARM repeat domains for protein targeting in plants has been studied in a few examples. The two F-box-containing proteins ARABIDILLO-1 and ARABIDILLO-2 that promote lateral root development carry a nuclear localization signal (NLS) and localize to the nucleus. In these proteins, the ARM repeat composition appears to allow for nuclear targeting in an NLS-independent manner (Coates et al., 2006). An ARM domain-containing fragment of the kinesin MRH2 that is involved in root hair tip growth was shown to bind to polymerized actin in vitro (Yang et al., 2007). Here, an ARM repeat domain was identified in plants that is sufficient to trigger plasma membrane association not only of SAUL1, but also of GFP and of the PUB-ARM protein PUB27 that normally resides in the cytoplasm (Figs 4, 5). Association of ARM repeat-containing proteins with membranes has been reported in other eukaryotes. The S. cerevisiae armadillo Vac8p, which functions in vacuole fusion and inheritance, is associated with the vacuolar membrane. In contrast to the situation in SAUL1, however, this association does not depend on the ARM repeats but on lipid modification (Fleckenstein et al., 1998; Pan and Goldfarb, 1998; Wang et al., 1998). The plasma membrane interaction domain in the Paramecium Nd9p involved in exocytotic membrane fusion is also located outside of its ARM repeat domain (Froissard et al., 2001). In animals, the cytosolic protein β-catenin, the mammalian homologue of the Drosophila armadillo gene product, can bind to interaction partners in different compartments (Yap et al., 1997). β-Catenin may serve as adaptor protein to anchor plasma membrane-localized cadherins, which regulate intercellular contact between epithelial cells at adherens junctions, to the actin cytoskeleton. Internal ARM repeats of β-catenin have been shown to be important for binding of β-catenin to the cytoplasmic domain of cadherins (Aberle et al., 1994; Hulsken et al., 1994; Pai et al., 1996). In addition to its cytoskeletal function, β-catenin has an important role in the regulation of gene expression through Wnt signalling during development (Behrens, 2000). This function requires the interaction with interaction partners in the nucleus and cytoplasm, namely TCF-type transcription factors, the tumour suppressor APC, and axin. Interestingly, binding to these proteins depends on the same ARM repeat domain as binding to cadherin (Graham et al., 2000; von Kries et al., 2004). It could be demonstrated that this domain is essential and sufficient for plasma membrane association of SAUL1. The deletion of this domain or of single ARM repeats in this domain resulted in the loss of plasma membrane association (Fig. 4). Generally, ARM repeat domains are important for protein–protein interactions (Huber et al., 1997; Conti and Kuriyan, 2000; Coates, 2003). In addition to the PUB-ARM proteins, sequence analyses have detected >50 additional

Fig. 6. Plasma membrane association of SAUL1 is important for its in vivo function. (A and B) In contrast to wild-type plants (A), saul1-1 mutants challenged with low light showed growth arrest and early senescence (B). (C) saul1-1 mutants stably transformed with the CaMV35S-promoter:SAUL1-GFP construct showed complementation of the senescence phenotype. (D) Stable transformation of saul1-1 mutants with the CaMV35S-promoter:SAUL1ΔARM7–11-GFP construct did not complement the early senescence phenotype. The arrow points to a leaf of a seedling that is not homozygous for the mutation in SAUL1 and thus does not show a senescence phenotype. (E) Plasma membrane association of SAUL1-GFP was confirmed by monitoring GFP fluorescence in saul1-1 plants transformed with CaMV35S-promoter:SAUL1-GFP. (F) SAUL1ΔARM7–11-GFP localized to the cytosol and nucleus as indicated by GFP fluorescence in saul1-1 plants transformed with CaMV35S-promoter:SAUL1ΔARM7–11-GFP. Arrows point to nuclei in focus. Scale bars in E and F represent 50 μm.

Previously, it has been shown that the PUB-ARM E3 ubiquitin ligase SAUL1 is a suppressor of premature senescence and cell death (Raab et al., 2009). Together with the plasma membrane association and its relevance for SAUL1 function in vivo presented here, this suggests that SAUL1 modifies target proteins at the plasma membrane to suppress premature senescence and cell death in young Arabidopsis plants. Similarly, the Arabidopsis RING1 E3 ubiquitin ligase localizes to plasma membrane lipid rafts to modulate the fumonisin B1-induced programmed cell death pathway (Lin et al., 2008). In animals, extrinsic signalling leading to programmed cell death has recently also been shown to involve ubiquitin-dependent steps at the plasma membrane (Jin et al., 2009). Regarding dramatic changes in the transcriptome during senescence, it is tempting to speculate that SAUL1 may participate in processing membrane-bound transcription factors at the plasma membrane. Membrane-bound transcription factors have been described in Arabidopsis and, based on genome-scale analyses, many others have been predicted to localize to membranes (Iwata and Koizumi, 2005; Kim et al., 2006; Seo et al., 2008). Regulated ubiquitin/proteasome-dependent processing (RUP) at membranes has been suggested as a possible mechanism of transcription factor regulation and thus gene expression control (Hoppe et al., 2001). To address the actual function of SAUL1, future research is required to identify in vivo targets modified by SAUL1 at the plasma membrane.
