Return of chloroquine-sensitive *Plasmodium falciparum* parasites and emergence of chloroquine-resistant *Plasmodium vivax* in Ethiopia

Seleshi Kebede Mekonnen1,2,3,7*, Abraham Aseffa2, Nega Berhe1, Tilahun Teklehaymanot1, Ronald M Clouse5, Tamirat Gebru3,4, Girmay Medhin1 and Thirumalaisamy P Velavan3,6

Abstract

**Background:** Increased resistance by *Plasmodium falciparum* parasites led to the withdrawal of the antimalarial drugs chloroquine and sulphadoxine-pyrimethamine in Ethiopia. Since 2004 artemether-lumefantrine has served to treat uncomplicated *P. falciparum* malaria. However, increasing reports on delayed parasite clearance to artemisinin opens up a new challenge in anti-malarial therapy. With the complete withdrawal of CQ for the treatment of *Plasmodium falciparum* malaria, this study assessed the evolution of CQ resistance by investigating the prevalence of mutant alleles in the *pfmdr1* and *pfcrt* genes in *P. falciparum* and *pvmdr1* gene in *Plasmodium vivax* in Southern and Eastern Ethiopia.

**Methods:** Of the 1,416 febrile patients attending primary health facilities in Southern Ethiopia, 329 febrile patients positive for *P. falciparum* or *P. vivax* were recruited. Similarly of the 1,304 febrile patients from Eastern Ethiopia, 81 febrile patients positive for *P. falciparum* or *P. vivax* were included in the study. Of the 410 finger prick blood samples collected from malaria patients, we used direct sequencing to investigate the prevalence of mutations in *pfcrt* and *pfmdr1*. This included determining the gene copy number in *pfmdr1* in 195 *P. falciparum* clinical isolates, and mutations in the *pvmdr1* locus in 215 *P. vivax* clinical isolates.

**Results:** The *pfcrt* K76 CQ-sensitive allele was observed in 84.1% of the investigated *P.falciparum* clinical isolates. The *pfcrt* double mutations (K76T and C72S) were observed less than 3%. The *pfcrt* SVMNT haplotype was also found to be present in clinical isolates from Ethiopia. The *pfcrt* CVMNK-sensitive haplotypes were frequently observed (95.9%). The *pfmdr1* mutation N86Y was observed only in 14.9% compared to 85.1% of the clinical isolates that carried sensitive alleles. Also, the sensitive *pfmdr1* Y184 allele was more common, in 94.9% of clinical isolates. None of the investigated *P. falciparum* clinical isolates carried S1034C, N1042D and D1246Y *pfmdr1* polymorphisms. All investigated *P. falciparum* clinical isolates from Southern and Eastern Ethiopia carried only a single copy of the mutant *pfmdr1* gene.

**Conclusion:** The study reports for the first time the return of chloroquine sensitive *P. falciparum* in Ethiopia. These findings support the rationale for the use of CQ-based combination drugs as a possible future alternative.

**Keywords:** Malaria, *Plasmodium falciparum*, *Plasmodium vivax*, Ethiopia, *pfcrt*, *pfmdr1*, *pvmdr1*, *pfmdr1* gene copy number

Background

Malaria remains one of the major health problems in sub-Saharan Africa [1,2]. Though there are encouraging reports that malaria morbidity and mortality are declining [3], it is still an overwhelming public health problem, with an estimated 207 million cases and 627,000 deaths every year worldwide. Of all malaria deaths, 90% occur in sub-Saharan Africa, and 77% in children under five years of age [4]. One of the main obstacles to malaria control is the ability of the parasites to develop resistance to the administered anti-malarial drugs. Chloroquine (CQ) was the first antimalarial to be widely used in endemic areas, but CQ resistance was documented in Thailand in the late 1950’s, spread to African in 1974 [5], and subsequently came to East Africa in the early 1980’s [6]. Since 2009, there are increasing concerns and reports of delayed parasite clearance to administered artemisinin, especially in parts of Southeast Asia [7].

In Ethiopia, CQ treatment failure for Plasmodium falciparum and Plasmodium vivax treatment was documented in 1996 [8]. Therefore, in 1998 sulphadoxine-pyrimethamine (SP) replaced the CQ triple-dose (25 mg base/kg) regimen as the first-line drug for the treatment of uncomplicated P. falciparum and mixed infection of P. falciparum and P. vivax malaria. However, in a short time span P. falciparum also developed resistance to SP, leading to therapeutic failure of SP [9-12]. Artemether-lumefantrine (AL) also developed resistance to SP, leading to therapeutic failure of AL [13]. In Ethiopia, CQ resistance was documented in 1989 [33] and in northwestern Sumatra, Indonesia in 1995 [34]. CQ resistance in P. vivax in Ethiopia was reported in 2008, when four patients out of 83(4.8%) had recurrent parasitaemia on Day 28 [35]. Several studies at regular intervals are required to evaluate drug resistance based on the genetic diversity of circulating P. falciparum strains and their molecular markers for P. falciparum resistance to CQ and AL. Such studies will lay a basis to re-evaluate existing strategies in malaria control [36]. In the present study, the prevalence of mutations in pfcr and pfmdr1, the gene copy number of pfmdr1 in P. falciparum, and point mutations in pvmdr1 in P. vivax were investigated in clinical isolates from Southern and Eastern Ethiopia.

Methods

Study sites

A health institution-based study targeting febrile patients attending primary health facilities was conducted in Southern and Eastern Ethiopia. Samples from Southern Ethiopia were collected between the months of August and December, 2011, at three health centres: Omo Nada, Bala Wajo, and Arba Minch. In Eastern Ethiopia samples were collected in the Harar health centre between the months of October and December 2009. Malaria transmission in these study sites is seasonal, with higher transmission following the rainy seasons (between September and December, and between April and May).

Study samples

Study participants were recruited from the routine health delivery system. Self-presenting febrile patients attending health centers in Omo Nada (n = 713), Bala Wajo (n = 312), and Arba Minch (n = 391), and whose age was at least six months between August and December 2011, were eligible for the current study. Additionally self-presenting febrile patients attending Harar health centre
(n = 1,304) in eastern Ethiopia were also eligible for the study. An axillary temperature was measured to check for a fever. Patients with an axillary temperature of ≥37°C were considered febrile. Any patient reported as being infected either with *P. falciparum* or *P. vivax* or with a mixed infection using the existing health care delivery system within the target health centres were approached for consent immediately after receiving their laboratory result. For those who consented to be part of the study, approximately 5–10 μL of a finger-prick blood sample was collected. No additional clinical assessment was carried out at the time of recruitment. A total of 410 Southern and Eastern Ethiopian finger-prick blood samples collected on Whatman 3 mm filter paper tested positive by microscopy for either *P. falciparum* or *P. vivax*. Of these, 195 tested positive for *P. falciparum* (170 from Southern Ethiopia and 25 from Eastern Ethiopia), and 215 for *P. vivax* (159 *P. vivax* from Southern Ethiopia and 56 from Eastern Ethiopia). The blood spots were air-dried and stored in a separate, clean, sealed plastic bag at room temperature for further molecular analysis.

**Blood film management**

After fixing the thin film in methanol, both smears were stained with 3% Giemsa for 30 min and examined under oil immersion for malaria parasites. Thick films were used for parasite detection, and thin film for species identification. At least 100 fields examined under an oil-immersion lens were examined before ruling out infection.

**Detection of pfmdr1, pfcr and pvmdr1 polymorphisms**

DNA was isolated using the Qiagen DNA Mini Kit for blood and tissue (QIAGEN, Germany), following the manufacturer's instructions, and it was then stored at –20°C until use. Nested PCR was carried out as previously described elsewhere [37]. DNA samples were amplified by species-specific primer pairs (Table 1). For *pfcr*, *pfmdr1* and *pvmdr1* both the primary and nested amplifications were carried out in a 20 μL reaction volume containing 1X buffer, 2.5 mM MgCl₂, 200 μM dNTPs, 200nM primers, 1U Taq DNA-Polymerase, and 10 ng of DNA template on a PTC-200 Thermal cycler (MJ Research, USA). Each genus-specific amplification for *Plasmodium* was followed by a species-specific PCR. For amplifications, the study followed standard nested PCR procedure (Table 1). The PCR product of the first reaction was used as the template for the second in all nested PCRs. Amplicons that resulted from the nested PCRs were separated by electrophoresis on a 1.2% agarose gel, run with a 100 bp DNA ladder (Invitrogen, Karlsruhe, Germany). The presence of different *Plasmodium* species was re-confirmed by checking amplicon size. To identify relevant Single Nucleotide Polymorphisms (SNPs) in *pfmdr1*, *pfcr* and *pvmdr1*, PCR products were cleaned using Exo-SAP-IT (USB, Affymetrix, USA), and 1 μL of the purified product was used as a template for direct sequencing using the Big Dye terminator v. 2.0 cycle sequencing kit (Applied Biosystems, USA) on an ABI 3130XL DNA sequencer, according to the manufacturer's instructions [38]. All investigated

### Table 1 Primer pairs used to amplify and sequence *pfcr*, *pfmdr1* and *pvmdr1*

**Detection of *pfmdr1* gene copy number variations**
The *pfmdr1* gene copy number was estimated by TaqMan real-time PCR, as previously described [29]. Briefly, 10 ng of genomic DNA was amplified in a 25 μL volume of reaction mixture containing 1x TaqMan buffer (8% glycerol, 0.625 U DNA polymerase, 5.5 mmol/L MgCl2, 300 μmol/L dNTPs, 600 nmol/L passive reference dye ROX (5-carboxy-X-rhodamine), pH 8.3), 300 nmol/L of each forward and reverse primer, 100 nmol/L of each probe, and 5 μL of template DNA on a Corbett Research RG-3000 (Qiagen, Hilden, Germany). Thermal cycling parameters were as follows: pre-incubation at 95°C for 5 minutes, followed by 50 cycles of 15 seconds: 95°C and 1 minute at 58°C. Genomic DNA was as follows: pre-incubation at 95°C for 5 minutes, followed by 50 cycles of 15 seconds: 95°C and 1 minute at 58°C. Genomic DNA from *P. falciparum* reference 3D7, reported to have only one copy, was used as the calibrator [39], and *pfmdr1* copy number control, DNA from the Dd2 clone was used. The 2^ΔΔCt method of relative quantification [40] was used to estimate copy number. Using this cycle threshold (Ct) method to estimate copy numbers of unknown samples, a calibrator DNA template with known copy number was estimated by TaqMan as previously described [29]. Briefly, 10 ng of genomic DNA was amplified in a 25 μL volume of reaction mixture containing 1x TaqMan buffer (8% glycerol, 0.625 U DNA polymerase, 5.5 mmol/L MgCl2, 300 μmol/L dNTPs, 600 nmol/L passive reference dye ROX (5-carboxy-X-rhodamine), pH 8.3), 300 nmol/L of each forward and reverse primer, 100 nmol/L of each probe, and 5 μL of template DNA on a Corbett Research RG-3000 (Qiagen, Hilden, Germany). Thermal cycling parameters were as follows: pre-incubation at 95°C for 5 minutes, followed by 50 cycles of 15 seconds: 95°C and 1 minute at 58°C. Genomic DNA from *P. falciparum* reference 3D7, reported to have only one copy, was used as the calibrator [39], and *P. falciparum* β-tubulin as the house-keeping gene. For multiple *pfmdr1* copy number control, DNA from the Dd2 clone was used. The 2^ΔΔCt method of relative quantification [40] was used to estimate copy number. Using this cycle threshold (Ct) method to estimate copy numbers of unknown samples, a calibrator DNA template with known copies of the interest and a house-keeping gene which has the same copy number was utilized. The ΔΔCt calculation was as follows: ΔΔCt = (Ct target gene - Ct Pf β-tubulin) X - (Ct target gene - Ct Pf β-tubulin) Y, where X = unknown sample and Y = *P. falciparum* 3D7. The result was expressed in N-fold changes in X target gene copies normalized to *P. falciparum* β-tubulin according to the equation (amount of target) = 2^-ΔΔCt. Each sample was run as triplicate, and the mean and standard deviation of the three Ct values were calculated and computed for specificity as suggested earlier [29].

**Ethics**
Ethical approvals were obtained from the review boards of Aklilu Lemma Institute of Pathobiology (ALIPB), College of Health Sciences of Jimma University, College of Health and Medical Sciences of Haramaya University and Armauer Hansen Research Institute (AHRI). After obtaining informed consent and assent from either the patient or legal guardian, blood samples were collected from individuals positive for *P. falciparum* or *P. vivax*. The study participation was voluntary and had no influence on the treatment provision at the respective health facilities. All patient information was kept confidential. All individuals positive for *P. falciparum* were treated with AL, while *P. vivax* positive patients were treated with CQ.

**Results**
The observed frequencies of the investigated SNPs in the *pfmdr1*, *pfcrt* and the *pvmdr1* loci are summarized in Table 3. The *pfcrt* K76T (Lys76Thr) mutation was observed in only 15.9% (31/195) of the clinical isolates investigated compared to 84.1% (164/195) wild type allele that were sensitive to CQ. The *pfcrt* C72S (Cys72Ser) was observed only in 3.6% (7/195) compared to 96.4% (188/195) wild type allele that were sensitive to CQ. The *pfmdr1* double mutations (K76T and C72S) were observed in less than 2.6% of individuals (5/195) Table 3. For the investigated *pfmdr1* locus N86Y (Asn86Tyr), the mutation was observed in 14.9% (29/195) of the clinical isolates compared to 85.1% (166/195) wild type that carried sensitive alleles. The investigated *pfmdr1* locus Y184 (Tyr184Phe), only 5.1% (10/195) of the clinical isolates carried the mutant. None of the investigated 195 *P. falciparum* clinical isolates carried S1034C, N1042D and Y188F polymorphisms. For the investigated *pvmdr1* locus Y976 (Tyr976Phe), the mutation was observed in 32.6% (70/215) of the clinical isolates compared to 67.7% (145/215) wild type that carried sensitive alleles, whereas the investigated F1076 (Phe1076Leu) carried no drug resistant mutants Table 3. Of the all investigated *P. falciparum* clinical isolates from Southern and Eastern Ethiopia, only one copy of *pfmdr1* gene copy number was observed.

The frequency of SNPs in the *pfmdr1*, *pfcrt* and the *pvmdr1* loci in Southern and Eastern Ethiopia are summarized in Table 4. The *pfcrt* K76T mutation in Southern Ethiopia was 13.5% (23/170) of the clinical isolates investigated compared to 86.5% (147/170) wild type allele that were sensitive to CQ. The *pfmdr1* locus N86Y was observed in 12.9% (22/170) compared to 87.1% (148/170) wild type allele that were sensitive to CQ. In Eastern Ethiopia, SNPs in the *pfmdr1* locus N86Y and *pfcrt* locus K76T were 28.0% (7/25) and 96.4% (164/170) respectively. On the other hand, for the investigated *pvmdr1* locus Y976 (Tyr976Phe), the mutation was observed in 37.1% (59/160) of samples.

**Table 2 Investigated point mutations in *pfmdr1*, *pfcrt* and *pvmdr1* genes**

| Codon position | Pfd1 locus | Pfcrt locus | Pvmdr1 locus |
|---------------|-----------|-------------|--------------|

**Discussion**

The aim of the current study was to investigate the prevalence of mutant SNPs in the loci pfmdr1, pfcr1, and pvmdr1, as well as copy number variations in pfmdr1, all of which are associated with anti-malarial drug resistance. A large proportion of P. falciparum clinical isolates in this study (84.1%) carried the chloroquine-resistant pfcr1 K76 allele. Previously it has been reported that the CQ-resistant mutation pfcr1 K76T is a strong predictor of overall CQ resistance, and thus it is used as a biomarker of CQ resistance [16]. It appears that CQ-susceptible Plasmodium falciparum isolates are back in circulation in Ethiopia.

The finding of this study does not support a previous study conducted in Ethiopia that reported a 100% frequency of the pfcr1 T76 mutation, and an 81% frequency of the mutation pfmdr1 Y86 in P. falciparum [41]. However, the current finding is in line with studies conducted in two East African countries [27,42], where the frequency of the pfcr1-T76 resistance alleles were repopulated with the sensitive ones after many years of CQ withdrawal. Studies showed that pfcr1 mutations at codons 72 to 76 with non-synonymous substitutions result in wildtype pfcr1 CVIET or other pfcr1 haplotypes CVIET or SVMNT that have been associated with CQ resistance[43]. The wild type pfcr1 CVIETN haplotypes were observed in 187 (95.9%) of the P. falciparum isolates. The mutant pfcr1 SVMNT was carried by 4.1% (8/195) of the investigated isolates, and it was identical to that of chloroquine resistant isolates identified in Southeast Asia [44]. These are the first findings on the presence of the pfcr1 SVMNT haplotype in clinical isolates in Ethiopia. This is an interesting finding and novel to the study as the SVMNT haplotype is still very rare in Africa. So far few studies reported the presence of this haplotype in African countries [45-48], of this haplotype mostly associated with amodiaquine resistance and lower level of chloroquine resistance compared to CVIET [49,50]. The pfcr1 CVIET haplotypes were not detected here, although it is prevalent in Africa [51].

Concerning pfmdr1, while wild-type pfmdr1 is thought to transport and accumulate CQ in the parasites’ food vacuole, mutations N86Y, S1034C, N1042D, and D1246Y interfere with transportation of the anti-malarial drugs, leading to reduced CQ-sensitivity [14]. The percentage of wild-type alleles at codon 86 of pfmdr1 was 85.1% (166/195), which is higher than 81% present in Schunk in 2006 and 84.5% in Eshetu in 2010 [41,52]. It should be clear that the study by Schunk in 2006 was conducted 7 years before the current study. This is clear that as the time difference between these two studies is large and with reduced drug pressure on CQ over time might have contributed to the return of CQ susceptibility.

159) of the clinical isolates in Southern Ethiopia compared to 19.6% (11/56) in Eastern Ethiopia.

The pfcr1 haplotypes were reconstructed for mutations at codons 72–76 in all P. falciparum isolates. The pfcr1 wild type Cysteine-Valine-Methionine-Asparagine-Lysine (pfcr1 CVIET) mutates to either Cysteine-Valine-Isoleucine-Glutamate-Threonine (pfcr1 CVIET) or Serine-Valine-Methionine-Asparagine-Threonine (pfcr1 SVMNT) variants Table 5. The mutated pfcr1 SVMNT haplotype was observed in 4.1% (8/195) of the isolates, whereas pfcr1 CVIETN of wildtype was observed in 95.9% (187/195) Table 5. No pfcr1 CVIET haplotypes were observed.

Table 4 Distribution of pfcr1, pfmdr1 and pvmdr1 point mutations in the investigated clinical isolates in Southern and Eastern Ethiopia

| P. falciparum | SE no | SE (%) | EE no | EE (%) |
|---------------|-------|--------|-------|--------|
| Pfcrt only C72 | 5 | 2.9% | 2 | 8.0% |
| C72 and K76 | 4 | 2.4% | 1 | 4.0% |
| only K76 | 23 | 13.5% | 8 | 32.0% |

| Pfcrt and pfmdr1 K76 and N86 | 2 | 1.2% | 2 | 8.0% |

| Pfcrt and pfmdr1 only N86 | 22 | 12.9% | 7 | 28.0% |
| N86 and Y184 | 6 | 3.5% | 2 | 8.0% |
| only Y184 | 7 | 4.1% | 3 | 12.0% |

| Pfcrt and pfmdr1 P. vivax only Y976 | 59 | 37.1% | 11 | 19.6% |
| only F1076 | 0 | 0% |

Pfmdr1: Plasmodium falciparum multi-drug resistance 1; Pfcr1: Plasmodium falciparum chloroquine resistance transporter; Pvmdr1: Plasmodium vivax multi-drug resistance 1; SE: Southern Ethiopia; EE: Eastern Ethiopia.
The pfcr K76T mutation in Southern Ethiopia was 13.5% (23/170) of the clinical isolates investigated compared to 86.5% (147/170) wild type allele that were sensitive to CQ. The pfmdr1 locus N86Y was observed in 12.9% (22/170) compared to 87.1% (148/170) wild type allele that were sensitive to CQ. In Eastern Ethiopia, SNPs in the pfmdr1 locus N86Y and pfcr locus K76T were 28.0% (7/25) and 32% (8/25) respectively. There was no statistical difference between Southern and Eastern Ethiopia in SNPs in the pfmdr1 locus N86Y and pfcr locus K76T ($P = 0.9$).

Double mutations in pfmdr1 at positions Y976F and F1076L have been suggested to be associated with reduced chloroquine susceptibility to $P.\text{ vivax}$ in Thailand and Indonesia, the two countries where $P.\text{ vivax}$ is prevalent. Other studies have addressed whether chloroquine or amodiaquine treatment failure might be associated with $P.\text{ vivax}$ isolates carrying the Y976F substitution [53]. Pvcrt sequences from $P.\text{ vivax}$, the orthologue of pfmdr1, were analyzed for the presence of mutations at positions 976 and 1076, and we found that 32.6% (70/215) of the isolates carried the Y976F SNP. Mutations were not detected at codon 1076 in all $P.\text{ vivax}$ isolates studied here. On the other hand, for the investigated pfmdr1 locus Y976 (Tyr976Phe), the mutation was observed in 37.1% (59/159) of the clinical isolates from Southern Ethiopia compared to 19.6% (22/115) from Eastern Ethiopia.

In line with the current study, studies conducted in Madagascar and Brazil showed that F1076L cannot be taken as an indicator of drug resistance, but rather it is a geographic variant [46,53,54]. Earlier, in vivo studies conducted in Ethiopia confirmed the presence of drug resistant $P.\text{ vivax}$ [8,35]. However, these studies were confounded by the inherent difficulties associated with in vivo tests for relapsing malaria [55] and the difficulties in differentiating between re-infection, recrudescence, and relapse after treatment failure [56].

A high proportion (97.9%, 191/195) of samples had chloroquine (CQ)-susceptible alleles at both codon 76 of pfcr and codon 86 of pfmdr1. The rapid shift in $P.\text{ falciparum}$ from CQ-resistant to CQ-susceptible suggests that the removal of CQ for the treatment of $P.\text{ falciparum}$ or the pressure from AL that has been used since 2004 to treat $P.\text{ falciparum}$ malaria and mixed infection of $P.\text{ falciparum}$ and $P.\text{ vivax}$ or both may eventually lead to replacement of pfmdr1 resistance genes by susceptible parasite populations [42,57]. Our finding was consistent with observations from Malawi [57], Kenya [42], and Tanzania [27], where the withdrawal of chloroquine resulted in the rapid spread of a chloroquine-susceptible Pfcr K76 population. In Malawi, recovery of the susceptible Pfcr-K76 from <15% to 100% within 13 years of CQ withdrawal has been reported [57]. Moreover, a study confirmed that the pfmdr1 alleles 86 N, 184 F, and 1246D significantly increased in prevalence after AL treatment [58]. In another in vivo study, $P.\text{ falciparum}$ parasites carrying the chloroquine-susceptible Pfcr K76 allele was selected after treatment with AL [59].

It was difficult to determine whether the CQ-susceptible resurgence is due to back-mutations in the CQ-resistant allele or the expansion of surviving CQ-susceptible reservoir populations. Re-expansion appears to be more common in Africa, where transmission rates are higher and naturally immune individuals are more common than in Southeast Asia (where CQ-resistant alleles appear to have gone to fixation in many areas) [57]. It does not appear that CQ-resistant mutants in Ethiopia acquired mutations to compensate for the costs of being drug-resistant. It is believed that such compensatory mutations confer fitness levels greater than that of the original CQ-susceptible and CQ-resistant alleles [60]. CQ-susceptible alleles clearly have a selective advantage over resistant ones, pfmdr1 Y86 having rebounded from 100% to 11% in 6 years (for samples collected on 2009 from East Ethiopia) to eight years time (for samples collected on 2011 from South Ethiopia). On the other hand, N86Y mutation was rebounded from 81% to 9% [41,52].

In Ethiopia, due to resistance developed by $P.\text{ falciparum}$, replacement of SP by artemether-lumefantrine has been mandatory. Since 2004, artemether-lumefantrine has been the drug of choice for the treatment of $P.\text{ falciparum}$ malaria. Unlike Malawi, in Ethiopia CQ was partially withdrawn and is still the drug of choice for the treatment of uncomplicated $P.\text{ vivax}$. This finding shows that there has been strong selection for chloroquine-sensitive parasites after the nationwide replacement of chloroquine with SP. The return of chloroquine-susceptible alleles in a country like Ethiopia, which is endemic for malaria, can be considered a positive development toward replacing the expensive artemether-lumefantrine with a safe and cheap form of CQ in combination with other short-acting drugs. Likewise, in

malaria-endemic countries even partial returns of chloroquine sensitivity have a positive impact on public health [57].

Conclusion

The return of CQ-sensitive parasites is likely due to either CQ withdrawal for the treatment of *P. falciparum* or the pressure from AL since 2004 or both. The return of CQ-susceptible *P. falciparum* following declining CQ resistance will have its own contribution in the battle against malaria. If chloroquine susceptibility does become widespread in Ethiopia, the possibility of using chloroquine in the future as a combination therapy with other short-acting drugs with different pharmacokinetic and pharmacodynamics profiles will be an additional anti-malarial option. This is a positive development, since CQ is cheap, safe, well-tolerated, long-lasting, and easy-to-prepare molecule. Additional surveillance studies to investigate resistance markers of *pfmdr1* and *PfCRT* genes of *P. falciparum* in the same geographic area may help to assess the prevalence of anti-malarial resistance.

Competing interests

The authors have declared that they have no competing interests.

Authors’ contributions

SKM designed and performed the field study and experiments, data analysis with drafting first draft. AA, NB, TG, RC, TT and GM contributed to the study design and study samples and revisions of MS. TPV designed the experiment, contributed to the study and revisions of MS. All authors read and approved the final manuscript.

Acknowledgements

We thank all our study volunteers. We are grateful to all the health personnel at the field sites for their extensive help. A special thanks to Abebew Tiruneh, Albert Lalremruata and Justin Anthony for sharing their expertise.

Funding

SKM was supported by a DAAD fellowship to do laboratory work in University of Tübingen. The laboratory work was supported by internal grant to author TPV. Moreover, the field work for this research was supported by funds from the Sida and NORAD core grant to the Armauer Hansen Research Institute and University thematic research program of Addis Ababa University.
