AIM: To investigate killer inhibitory and activating receptor expression by natural killer (NK), natural killer T-like (NKT-like) and CD8+ T lymphocytes in patients with chronic hepatitis C virus (HCV) infection with elevated and with persistently normal alanine aminotransferase (PNALT).

METHODS: The percentage of peripheral blood Treg cells, KIR2DL3, ILT-2, KIR3DL1, CD160, NKG2D, NKG2C expressing NK, T and NKT-like cells, cytokine production and NK cytotoxicity were determined by flow cytometry. Twenty-one patients with chronic HCV infection with elevated alanine aminotransferase and 11 healthy volunteers were enrolled.

RESULTS: No significant differences were observed in the percentage of total T, NK or NKT-like cells between study groups. Comparing the activating and inhibitory
receptor expression by NK cells obtained from HCV carriers with PNALT and chronic HCV hepatitis patients with elevated alanine aminotransferase, NKG2D activating receptor expression was the only receptor showing a significant difference. NKG2D expression of NK cells was significantly lower in patients with chronic HCV hepatitis than in healthy controls and in HCV carriers with PNALT. Plasma TGF-β1 levels inversely correlated with NKG2D expression by NK cells. In vitro TGF-β1 treatment inhibited NK cells cytotoxic activity and downregulated NKG2D expression. CD8+ T cells from HCV carriers with PNALT showed significantly elevated expression of CD160, NKG2D and NKG2C activating receptors compared to chronic HCV patients with elevated alanine aminotransferase. Enhanced expression of inhibitory KIR2DL3 receptor, and decreased ILT-2 expression on NK cells were also found in chronic hepatitis C patients compared to healthy controls.

CONCLUSION: Our study demonstrated a complex dysregulation of activating and inhibitory receptor expression, such as decreased NKG2D and CD160 activating receptor expression and increased KIR2DL3 inhibitory receptor expression by NK and cytotoxic T cells and may provide further mechanism contributing to defective cellular immune functions in chronic hepatitis C. Increased NKG2D receptor expression in HCV patients with persistently normal ALT suggests an important pathway for sustaining NK and CD8 T cell function and a protective role against disease progression.

INTRODUCTION

More than 170 million people worldwide are chronically infected by hepatitis C virus (HCV)[1]. Approximately 20% of HCV infected patients resolves acute hepatitis and clears the virus, but most develop life-long infection, making HCV a leading cause of chronic liver disease, cirrhosis and hepatocellular carcinoma[2]. No vaccine is currently available to prevent hepatitis C[3]. The mechanisms favoring persistent infection are still poorly understood.

Approximately 30% of patients with chronic HCV (CHC) infection show persistently normal alanine aminotransferase (ALT) levels and are considered CHC carriers[4].

The host immune response to HCV involves both innate and adaptive arms of the immune system. Natural killer (NK) cells are key components of the innate antiviral immune response. NK cells, a subset of lymphocytes, represent between 5% and 15% of mononuclear cells in the peripheral blood and up to 45% in some organs, such as the liver. The major functional role of NK cells is the defense against tumor cells and lyses of virus-infected cells[5]. However, given their potent cytotoxic and cytokine secretion potential, their activity needs to be tightly regulated. The activation state of an NK cell is determined partly by the interaction of activating and inhibitory signals after interaction of surface NK cell receptors, including the highly diverse killer Ig-like receptor (KIR) family, with ligands found on target cells.

Previous results from our laboratory showed an impaired NK activity in chronic hepatitis[6]. Therefore, altered function of NK cells might be one of the mechanisms by which viruses escape the immune system. Activating receptors on NK and T cells might provide not only the machinery to induce proliferation and fight off infection, but also to support maintenance of the cells critically needed under conditions of extended viral infections during CHC.

There is new evidence that NK cells also can be activated to negatively regulate T cell responses because they can produce interleukin-10 (IL-10)[7,8]. Under conditions of continued stimulation – like CHC infection - IL-10 response by NK cells could limit the magnitude of CD8 T cell response and protect from T cell-mediated disease. If the NK cells are not regulated properly, the regulation is lost with detrimental consequences.

Natural killer T-like (NKT-like) cells are a sublineage of T cells that share characteristics of conventional T cells and NK cells and bridge innate and adaptive immunity[9]. The most characteristic immunoregulatory function
of NKT cells is their ability to promptly secrete large amounts of Th1 and Th2 cytokines including interferon-γ (IFN-γ) and IL-4, respectively, upon stimulation[10]. Downstream, this culminates in the activation of different cell types of the innate immune system such as macrophages, NK cells, and dendritic cells as well as effector T cells of the adaptive immune system.

Although shown to mediate immunity against a wide range of pathogenic microbes, including bacteria, fungi, parasites, and viruses, the mechanism(s) by which NKT cells are activated during infection is still unclear. NKT-like cells are abundant in the liver; however, their role in the control of hepatitis C virus infection remains to be determined[11].

CD8+ T cells are important in viral elimination by using direct killing of infected cells and non-cytotoxic mechanisms such as the secretion of antiviral cytokines [IFN-γ or tumor necrosis factor (TNF)-α][12]. Despite the detection of HCV-specific CD8+ T cells in the peripheral blood and the intrahepatic lymphocytic infiltrate in patients with chronic hepatitis C, the virus can persist. This persistence in spite of the presence of these cytotoxic cells is still unexplained and suggests that cell killing is not sufficient to eliminate the virus. Studies in humans have revealed that even strong CD8+ T cell responses in the acute phase of infection may not be adequate to prevent progression to chronicity[13-15]. Several investigators have clearly shown that HCV-specific CD8+ T cells have functional defects during chronic infection, as indicated by impaired IFN-γ production, cytotoxic effector functions, and in vitro proliferation[16,17]. While the mechanisms responsible for the dysfunctions of HCV-specific T cells in chronically infected patients remain unclear, recent studies suggest a major contribution of regulatory T cells.

To better characterize the immune defects underlying chronic viral persistence, in this study we focus our analysis on killer inhibitory and activating receptor expression in patients with chronic hepatitis C virus infection with elevated ALT and also in patients with CHC carriers with persistently normal ALT (PNALT) by NK, NKT-like and CD8+ T lymphocytes, given the central role played by these cells in the control of viral infections. Progress in the understanding of antiviral immune responses in CHC carriers with PNALT could elucidate key mechanisms playing a role in the control of viral infection.

**MATERIALS AND METHODS**

**Patients**

Persistently normal ALT was defined as ALT < 30 IU/L in men, ALT < 19 IU/L in women measured every 3 mo over an 18-mo period. Patients with Fibroscan result suggesting > F1 liver fibrosis (LS > 7.0 kPa) were excluded from the CHC with PNALT group. Eleven age-matched healthy blood donors served as controls.

All HCV subjects were seronegative for anti-HIV 1, 2 antibodies (ELISA 2.0, Abbott, Wiesbaden, Germany), and HBsAg (Hepanostica Uniform II, Organon Teknika, Oss, The Netherlands), and were positive for both anti-HCV antibody and HCV-RNA. Diagnosis of chronic hepatitis C was established by means of histology in all symptomatic patients, but liver biopsy was not performed in CHC carriers with PNALT.

**HCV markers**

Anti-HCV antibody was examined using enzyme-linked immunoabsorbent assay (ELISA) (Detect-HCV Ab, Biochem Immunosystem, ITC, Canada). Serum HCV RNA detection and quantification were performed with Roche Cobs Amplicor HCV 2.0 assay (lower limit of detection < 50 IU/mL) and Cobs Amplicor HCV Monitor Assay (Roche Diagnostics) according to the manufacturer's instructions.

**Sample preparation**

Venous blood samples were collected in heparinized tubes and peripheral blood mononuclear cells (PBMC) were prepared by Ficoll-Paque density gradient centrifugation.

**Antibodies and flow cytometry**

Separated cells were washed in PBS and incubated for 30 min at room temperature with the monoclonal antibodies. The following monoclonal antibodies were used for these studies: FITC-conjugated anti-CD3, anti-CD8, anti-CD4, PE-conjugated anti-CD25, anti-KIR2DL3 (CD158b), anti-ILT-2 (CD85), anti-NKG2C, anti-CD160, anti-NKG2D, anti-KIR3DL1 (CD158e) and APC-conjugated anti-CD56. After washing the cells in PBS, cells were fixed with 4% paraformaldehyde, stored at 4 °C, in dark, to be processed for FACS analysis. At least 10000 cells were analyzed on the FACS Calibur flow-cytometer (Becton Dickinson Immunocytometry Systems, Erembodegen, Belgium) after single gating on lymphoid cells for all mAb combinations. The percentage of positive cells was calculated using Cellquest software (Becton Dickinson, San Diego, CA, United States). Figure 1 shows the gating technique used to detect different lymphocyte subpopulations with representative flow cytometric dot plots. The effect of TGF-β1 treatment on NKG2D, CD160 and KIR2DL3 expression by NK cells.

PBMC were separated from heparinized venous blood on Ficoll-Paque gradient. One million cells were treated with recombinant active TGF-β1 protein (1 ng/mL) for 48 h at 37 °C in a tissue culture incubator. NKG2D, CD160 and KIR2DL3 expression by NK cells was determined by flow cytometry.

**NK and CD8+ T separation and cytometric bead array**

Natural killer and CD8+ T cells were separated by MACS Cell Separation Technology (all reagents and instruments from Miltenyi Biotec, Frank Diagnosztika Kft., Budapest, Hungary). PBMCs were first magnetically labeled with CD56 or CD8 MicroBeads.
manufacturer’s instructions and CD56+ or CD8+ T cells were positively selected on the cell separation column. In the next step, the magnetic beads bound to the cell surface were enzymatically released from the CD56+ cells, which were then magnetically labeled with CD3 MicroBeads and the CD3+ subpopulation positively selected to compose the CD3+CD56+ T cell population. The remaining fraction of the CD56+ cells, which did not bind the CD3 beads composed the CD3-CD56+ NK cell population. Purity was greater than 95%. CD8+ and CD3-CD56+ cell populations were stimulated with 1 µg/mL of ionomycin and 25 ng/mL of PMA (Sigma-Aldrich, Sigma-Aldrich Kft., Budapest, Hungary) and effector cells were added to 25 × 10^6 target cells together. These cell mixtures were incubated for 30 s at 1200 rpm to pellet the effector and target cells together. These cell mixtures were incubated for 4 h at 37 °C in 5% CO₂. After incubation the cell mixture was centrifuged at 1200 rpm and stained with propidium iodide (PI, 5 μg/mL, Sigma, Hungary). Dead target cells were identified by simultaneous PKH67 and PI-positive. Target cells incubated without effector cells were used to assess spontaneous cell death. The percentage of lysed target cells was calculated by subtracting background (spontaneous cell death) expression from experimental samples. Cytotoxicity was expressed as the percentage of lysed target cells in each effector-to-target ratio.

Cytotoxic assay for NK cell activity
Cytotoxicity was determined as described earlier. Cytotoxic activity of NK cells was evaluated by FACS analysis. Target cells (1 × 10⁶) were pre-stained with the green fluorescent membrane dye PKH67 (Sigma, Hungary) and effector cells were added to 25 × 10⁶ target cells to yield effector to target (E:T) ratios of 12.5:1, 25:1, and 50:1. The tubes were centrifuged for 30 s at 1200 rpm to pellet the effector and target cells together. These cell mixtures were incubated for 4 h at 37 °C in 5% CO₂. After incubation the cell mixture was centrifuged at 1200 rpm and stained with propidium iodide (PI, 5 µg/mL, Sigma, Hungary). Dead target cells were identified by simultaneous PKH67 and PI-positive. Target cells incubated without effector cells were used to assess spontaneous cell death. The percentage of lysed target cells was calculated by subtracting background (spontaneous cell death) expression from experimental samples. Cytotoxicity was expressed as the percentage of lysed target cells in each effector-to-target ratio.
PBMC were separated from heparinized venous blood on Ficoll-Paque gradient. One million cells were treated with recombinant active TGF-β1 protein (1 ng/mL) for 48 h at 37 ℃. Following incubation we determined cytotoxicity of NK cells by flow cytometry.

**Statistical analysis**

Statistical analysis was performed using non-parametric Mann-Whitney U-test with statistical software SPSS version 11.0 package (SPSS, Inc. Chicago, IL, United States) (Figures 2-5). Results are expressed as mean value ± standard error of the mean (SEM). Statistical comparisons were made by using one-way ANOVA with Bonferroni correction (Figures 6 and 7). The results were expressed as the mean value ± SEM. Differences were considered significant if the P value was equal to or less than 0.05. Correlation between variables was assessed by calculating Spearman rank correlation coefficient. Differences were accepted as significant at a level of P < 0.05.

**RESULTS**

**Patients**

Twenty one patients with CHC infection with elevated ALT > 2 × ULN (11 males, 10 females, mean age: 57 years; range 38-70 years) and 11 (2 males, 9 females, mean age: 56 years; range 41-63 years) HCV carriers with persistently normal ALT were studied.

**Lymphocyte frequency**

No significant differences were observed in the percentage of helper (CD4+) or cytotoxic (CD8+) T cells, regulatory (CD4+CD25+stat5+) T cells, NK (CD3-CD56+) or NKT-like (CD3+CD56+) cells in peripheral blood of patients with CHC hepatitis with elevated ALT compared to CHC patients with PNALT and also to

The solid bars represent medians; the boxes indicate the interquartile ranges and the lines show the most extreme observations. Differences were considered statistically significant for P values ≤ 0.05. HCV: Hepatitis C virus; ALT: Alanine aminotransferase; PNALT: Persistently normal ALT; NK: Natural killer cell.
healthy controls (Table 1).

**Activating and inhibitory NK cell receptor expression by NK cells in the peripheral blood from patients with CHC with elevated ALT or PNALT and in healthy individuals**

The phenotypes and functional activities of various populations of innate effectors have been reported to be impaired in all stages of HCV infection[6,19-21]. The balance of activating and inhibitory signals through the killer activating and the inhibitory receptors control NK cell activity. Since the role of NK cells determining disease inflammatory activity reflected by ALT elevation in chronic hepatitis C is not clear, we investigated different activating and inhibitory NK cell receptor expression by NK cells in patients with CHC with elevated ALT or PNALT.

CD160 and NKG2D activating NK cell receptor expression was significantly lower in patients with CHC infection than in healthy controls (Figure 2A and D). NKG2D expression by NK cells was significantly lower than CHC carriers (Figure 2G). NK cells can be divided into two populations based on the intensity of the CD56 marker at the cell surface. CD56\textsuperscript{dim} NK cells are the more cytotoxic subset, whereas CD56\textsuperscript{bright} cells are poorly cytotoxic and preferentially secrete cytokines[22]. The majority of NK cells were of the CD3-CD56\textsuperscript{dim} phenotype and our data shows that this cell population represents the above mentioned alterations in activating receptor expression by NK cells (Figure 2B, E and H). In contrast to CD56\textsuperscript{dim} cells, we found no significant difference in the killer activating NK cell receptor expression by CD56\textsuperscript{bright} cells between the investigated groups (Figure 2C, F and I).

An enhanced expression of inhibitory KIR2DL3 receptor on NK cells was found in peripheral blood of patients with CHC infection and also in CHC carriers.
with PNALT in comparison to healthy controls (Figure 3A). No significant differences were found between study groups in regard to expression of ILT-2 on NK cells (Figure 3D-F). KIR3DL1 inhibitory NK cell receptor expression was significantly decreased by NK, CD56 \textsuperscript{dim} and CD56 \textsuperscript{bright} cells in patients with CHC irrespectively of ALT compared to healthy individuals (Figure 3G-I).

**Activating and inhibitory receptor expression by CD8\(^+\) T cells**

Significantly lower percentage of CD160, NKG2D and NKG2C activating receptor expressing CD8\(^+\) T cells were observed in HCV carriers with PNALT compared to healthy controls (Figure 4A-C). No significant differences were found between study groups in regard to expression of ILT-2 on NK cells (Figure 4D-F). KIR2DL3 expression was significantly decreased by NK, CD56 \textsuperscript{dim} and CD56 \textsuperscript{bright} cells in patients with CHC irrespectively of ALT compared to healthy individuals (Figure 4E-G).
were found in patients with CHC hepatitis than in healthy controls and in CHC carriers with PNALT. (Figure 4A-C). We found no difference in the percentage of inhibitory receptor (KIR2DL3 and ILT-2) expression by CD8+ T cells in patients with CHC infection compared to healthy controls (Figure 4D and E).

**Activating and inhibitory NK cell receptor expression by NKT-like cells**

No significant difference was found between healthy controls and patients with HCV infection with respect to expression of NKG2D on NKT-like cells (Figure 5A). KIR2DL3 inhibitory NK cell receptor expression by NKT-like cells revealed an enhanced proportion of KIR2DL3-expressing cells in peripheral blood of patients with CHC in comparison to healthy controls (Figure 5B). KIR3DL1 inhibitory receptor expression -similarly to NK cells- was significantly decreased on NKT-like cells in patients with CHC irrespective of ALT compared to healthy individuals (Figure 5D).

**Alteration of cytokine production by NK and CD8+ T cells in CHC infection**

NK cells produced significantly higher IL-10, TNF-α and IFN-γ in patients with CHC compared to healthy controls (Table 2). In addition, IL-2, IL-4, IL-5, and...

Statistical comparisons were made by using the ANOVA tests. The results were expressed as the mean value ± SD. HCV: Hepatitis C virus; ALT: Alanine aminotransferase; PNALT: Persistently normal ALT; NK: Natural killer cell.

Cytotoxicity of NK cells and the effect of in vitro TGF-β1 treatment

Earlier we demonstrated that TGF-β1 levels significantly higher in patients with chronic hepatitis C with elevated ALT compared to PNALT group and healthy individuals. TGF-β1 levels produced by CD8+ T cells compared to healthy individuals. Only IL-10 differed significantly between PNALT and elevated ALT group. CD8+ cells of CHC carriers with PNALT produced significantly higher amount of IL-10 compared to CHC hepatitis group (Table 2).

Effect of TGF-β1 on NKG2D expression of freshly isolated NK cells

To investigate if TGF-β1 was responsible for down-modulation of NKG2D, we incubated freshly isolated NK cells from healthy volunteers with 1 ng/mL TGF-β1 for 48 h and analyzed NKG2D expression by FACS. Incubation of NK cells with TGF-β1 significantly down-regulate surface NKG2D expression by NK cells (63.08 vs 36.21, P < 0.01). In contrast, TGF-β1 did not alter the level of other NK receptors, including the activating NK cell receptor, CD160 (37.47 vs 34.04 NS) or the inhibitory NK cell receptor, KIR2DL3 (11.05 vs 11.04 NS). These data suggest that TGF-β1 specifically down-modulates NKG2D without affecting other NK receptors.

Together, our data strongly suggest that secretion of TGF-β1 in CHC patients can down-modulate NKG2D expression by NK cells (Figure 6c). Plasma TGF-β1 levels inversely correlated with NKG2D expression by NK cells in CHC infected individuals (Figure 7).

DISCUSSION

Following acute HCV infection a majority of healthy adults will develop persistent viremia. Effective clearance of an acute viral infection typically requires the coordinated function of multiple arms of the immune system, including the innate immune system (interferons, NK and NKT-like cells), as well as the acquired immune response specific to a given pathogen (CD4+ and CD8+ T cells). A functional impairment of NK, NKT-like and CD8 T cells has been reported in CHC infections by several observations, and different mechanisms have been proposed to explain this defective function[5,19-21,24].

Natural killer cell receptors are important regulators of NK and CD8+ T cell functions. Regarding the fact that impaired activities of CD8+ T[6,20] and NK cells[19,21,24] have been reported in patients with chronic hepatitis C infection, we analyzed whether dysregulation of NK cell receptors on these cell might be involved in the inefficient cellular immune response observed in chronic hepatitis C. In this study we analyzed the expression of different activating and inhibitory NK cell receptors in CHC patients with elevated and with persistently normal ALT.

We found that the percentages of NKG2D or CD160 activating receptor positive NK and CD8+ T cells were significantly decreased in CHC patients with elevated ALT compared to healthy individuals. This discrepancy was not found in CHC infected patients with persistently normal ALT. CD8+ T cells from CHC carriers with PNALT showed significantly elevated expression of CD160, NKG2D and NKG2C activating receptors compared to CHC patients with elevated ALT. Comparing the activating and inhibitory receptor expression by NK cells obtained from CHC carriers with PNALT and CHC hepatitis patients with elevated ALT,
NK2G2D activating receptor expression was the only receptor showing a significant difference. Investigating CD56<sup>dim</sup> NK cells, NK2G2D receptor expression was significantly elevated in persistently normal ALT group compared to CHC hepatitis patients.

Analyzing inhibitory NK cell receptors expressed by CD8+ T, NK or NKT-like cells, we did not find any difference in the expression of KIR2DL3, I-LT-2 or KIR3DL1 between patients with CHC infection with elevated ALT and CHC carriers with PNALT. Interestingly KIR3DL1 expression by NK and NKT-like cells was significantly lower in patients with chronic hepatitis C with elevated ALT compared to healthy individuals. On the other hand KIR2DL3 expression by NK and NKT-like cells were significantly increased in patients with CHC infection with elevated ALT and CHC carriers with PNALT compared to healthy individuals.

The mechanisms by which NK and NKT-like cells in hepatitis express KIR2DL3 at considerable high levels remain elusive. One possibility is that the expression levels of NK receptors may be modified by various types of cytokines released under chronically inflamed conditions. Given previous findings that high level of serum TGF-β production were observed in CHC infected patients<sup>[32]</sup> and that TGF-β can up regulate the expression of inhibitory receptors on NK cells<sup>[32]</sup> we hypothesized that TGF-β would contribute to the high expression of KIR2DL3 on NK and NKT-like cells in CHC infection. We found that TGF-β1 significantly down-regulated surface NK2G2D expression by NK cells, but did not alter the level of other NK receptors, including the activating NK cell receptor CD160 or the inhibitory NK cell receptor KIR2DL3, suggesting that other factors, including the virus itself, play a role in the modulation of activating or inhibitory receptor expression.

The activation status of NK, NKT-like and CD8+ T cells depends on the balance between activating and inhibitory signals delivered by surface receptors. Thus, our present findings of up-regulated expression of inhibitory receptors combined with the concomitant down-regulation of activating receptors synergistically leads to the dominant delivery of inhibitory signals to NK, NKT cells and KIR receptor-positive T cells. This altered receptor expression is reflected by impaired cytotoxic function of NK cells. Our data agree with other studies<sup>[27,28]</sup>, which reported a significant reduction in NK cytotoxic activity in patients with CHC infection, but disagree with several other studies<sup>[24,29]</sup>

Our results show that NK cells from CHC carriers with PNALT have significantly higher cytotoxic activity compared to patients with CHC with elevated ALT or healthy individuals. Since NK2G2D expression by NK cells in PNALT patients was at normal level we hypothesize that further factors may be involved in the regulation of their activity.

The pathogenesis of impaired CD8 response in CHC infection still remains partially understood. To further clarify this issue, in this study, we looked for activating and inhibitory receptor expression by CD8+ T cells. Our results show that CD8 T cell triggering can be hindered by engagement of inhibitory natural killer cell receptors, which are expressed on previously activated CD8 T cells. Although we found no differences in the expression of inhibitory receptor expression by CD8+ T cells between healthy individuals and HCV infected patients, but we found that activating NK receptors are expressed at significantly lower frequencies on CD8+ T cells during CHC infection. These findings suggest that decreased expression of activating NK receptors may play a role in HCV infection, possibly by inhibiting CD8 T-cell triggering.

Other factors such as cytokines may also play an important role during CHC infection<sup>[30–32]</sup>. IL-10 has largely been appreciated for its direct and indirect inhibitory effects on several T cell responses. IL-10 has been shown to contribute to regulation of immunopathology. The increased production of IL-10 by CD8+ T cells in CHC patients with persistently normal ALT reported in this paper is supposed to be important for limiting CD8 T cell response and contributing to asymptomatic virus carrier state. The NK cells of CHC carriers with PNALT produced significantly higher level of IL-4 and TNF-α, together with high cytotoxic activity compared to patients with CHC infection. We showed that cytokine pattern of NK cells and CD8+ T cells are

Concentrations of cytokines are given in picograms per milliliter (mean ± SD). *P < 0.05, **P < 0.02, ***P < 0.001, vs healthy individuals, significantly different; *P < 0.05 vs symptomatic individuals, significantly different. HCV: Hepatitis C virus; ALT: Alanine aminotransferase; PNALT: Persistently normal ALT; NK: Natural killer cell; IL-2: Interleukin-2; TNF-α: Tumor necrosis factor α; IFN-γ: Interferon-γ.
shifted towards a virus-permissive profile in patients with CHC infection which may ultimately contribute to HCV chronicity.

A major unresolved issue is the exact role of immune cells in different patient populations with acute and chronic hepatitis C virus infection. Further investigations are needed to clear whether NK, NKT-like and CD8+ T cells expressing various activating and inhibitory receptors could lead to viral clearance.

In conclusion we found complex dysregulation of activating and inhibitory receptor expression, such as decreased NKG2D and CD160 activating receptor expression and increased KIR2DL3 inhibitory receptor expression by NK and cytotoxic T cells in patients with chronic hepatitis C contributing to defective cellular immune functions. NKG2D receptor expression was significantly elevated in CHC infected patients with persistently normal ALT suggesting an important pathway for sustaining NK and CD8 T cell function and its critical role in protection against disease progression.

**COMMENTS**

**Background**

The host immune response to hepatitis C virus (HCV) involves both innate and adaptive arms of the immune system. Natural killer (NK) cells are key components of the innate antiviral immune response.

**Research frontiers**

To better characterize the immune defects underlying chronic viral persistence, the authors focus their analysis on killer inhibitory and activating receptor expression in patients with chronic HCV (CHC) infection with elevated alanine aminotransferase (ALT) and also in patients with CHC carriers with persistently normal ALT suggesting an important role in protection against disease progression.

**Innovations and breakthroughs**

The authors found complex dysregulation of activating and inhibitory receptor expression by NK and cytotoxic T cells in patients with chronic hepatitis C contributing to defective cellular immune functions.

**Applications**

The percentage of Treg cells, KIR2DL3, ILT-2, KIR3DL1, CD160, NKG2D, NKG2D expressing NK, T and NKT-like cells, cytokine production and NK cytotoxicity were determined by flow cytometry.

**Terminology**

Persistently normal ALT was defined as ALT < 30 IU/L in men, ALT < 19 IU/L in women measured every 3 mo over a 18-mo period.

**Peer-review**

The manuscript described some phenotypical and functional differences in peripheral lymphocyte subsets between CHC patients with high and normal ALT. They describe a different expression in one NK activating receptor that could be related with TGF-β regulation. The manuscript is well written and the methodology is properly done.
