A Novel Medium for Enhancing Callus Growth of Hazel (Corylus avellana L.)

Mina Salehi¹, Ahmad Moieni¹ & Naser Safaie²

Paclitaxel is a powerful antimitotic agent with excellent activity against a range of cancers. Hazel has been described as a paclitaxel-producing species among angiosperms. Fast-growing callus is a prerequisite for the success of callus production and then paclitaxel production. Therefore, optimizing the medium culture for enhancing callus growth is a crucial step for paclitaxel production. In this research, Murashige and Skoog (1962) (MS) medium was optimized for improving callus growth of hazel (Corylus avellana L.). The M_{10} medium (MS medium with pH 6.0 and supplemented with 1000 mg l^{-1} spirulina powder, 1000 mg l^{-1} casein hydrolysate and 3 g l^{-1} gelrite) significantly improved hazel callus growth. This modified MS medium increased callus fresh weight (55.8%) as compared to the control. M_{10} medium increased fatty acids yield of callus (66.7%) as compared to the control. Liquid M_{10} medium maintained growth over a longer period of time and also increased slightly, the paclitaxel production as compared to the control. This novel medium is promising for facilitating the mass production of hazel callus as a source of valuable metabolites including paclitaxel, linoleic and oleic acids.

Paclitaxel is a powerful antimitotic agent with excellent activity against a range of cancers. The major limitation in the extensive use of this valuable secondary metabolite is its low supply, since Taxus spp. contains very low amounts of paclitaxel. Extraction of paclitaxel from this tree has imposed important ecological effects, resulting in the extinction of Taxus species. Plant cell suspension culture is considered as the most promising approach to the production of paclitaxel. The availability of this drug is still restricted and its cost is very high, mainly due to the recalcitrant behavior of Taxus spp. under in vitro conditions. Therefore, the search for alternative sources of paclitaxel was considered as crucial. In addition to Taxus spp., hazel (Corylus avellana) has also been described as a paclitaxel-producing species through bioprospection among angiosperms. The major advantages of producing paclitaxel through hazel cell cultures are that hazel is widely accessible and its in vitro cultivation is easier than that of yew. It is stated that in vitro cultures of C. avellana can become a promising and cheaper source for paclitaxel production. Besides the use of the nuts of hazel tree as a source of protein, its leaves are used to relieve the symptoms of hemorrhoidal and varicose veins. The kernel and green leaf/flower portions of the hazel tree have antioxidant activity. It is found that the consumption of nuts is protective against cardiac morbidity and mortality.

In addition to the use of hazel cell cultures for paclitaxel production, hazel plantlets can be regenerated from callus tissues by differentiation induced by exogenous growth regulators. Plant regeneration from calli is possible by somatic embryogenesis or in vitro organogenesis. Meanwhile, infrequent somaclonal variants resulting from genetic diversity in somatic cells, mutations, chromosome aberrations and environmentally induced epigenetic changes can be isolated by plant regeneration of callus. Fast-growing callus is a key prerequisite for the success of mass callus production and then paclitaxel production, plant regeneration and transformation. Therefore, optimizing the culture medium for improvement of callus growth is a crucial step in mass callus production. For study of in vitro production of metabolites, in addition to a suitable protocol for callus induction, obtaining large amounts of callus biomass is a prerequisite. Also, setup of fast-growing in vitro cultures is an important stage for producing secondary metabolites from the plant cell cultures. One of the key problems in commercial production of secondary metabolites by plant cell cultures is slow growth of plant cells. The large-scale culture of low-growing cells is expensive and also basic laboratory...
analysis of such cells is tedious and difficult. Additionally, such slow growth rates require extreme precautions against contamination.

Regulation of medium nutrients significantly improves the callus growth. There are a few reports on the influence of medium composition on embryogenic induction and also, the best method for inducing shoot organogenesis in hazel, but no sufficient information is available regarding the influence of different nutrient concentrations in the culture medium on callus growth of *C. avellana*. Recently, a suitable callus was obtained from *C. avellana* in our laboratory and optimization of hazel callus mass production was tried. For this purpose, effects of different concentrations of some inorganic ingredients of Murashige and Skoog (1962) (MS) as well as the effects of spirulina powder (*Arthrospira platensis*), casein hydrolysate and some amino acids on hazel callus production were investigated.

**Results and Discussion**

The results of different MS medium amendments for improvement of growth of hazel callus indicated that these amendments enhanced callus growth.

**Effects of gelrite, pH 6.0 and medium volume increment on hazel callus growth.** The 22 modifications (Table S1) in the first experiment significantly affected all the studied characteristics (Table S2). Accordingly, medium volume increment resulted in the highest amount of relative growth rates (RGR) (0.069 d⁻¹) and relative fresh weight growth (RFWG) (4.65) which was significantly higher than that in the control (0.054 d⁻¹ and 2.87, respectively). In the present study, improved RGR and RFWG were obtained by the use of 3 g l⁻¹ gelrite as the gelling agent (Table S2). Bacterial gellan gum (like gelrite and phytagel) is the superior gelling agent for most plant tissue culture media due to its consistent quality and high purity. It was reported that gelrite is the best gelling agent for callus growth in *Ilex paraguariensis*. The presence of ionic impurities in both gelrite and agar may affect growth. Agar contains a large amount of sodium and also levels of sulfur and copper are significant. Gelrite has less organic impurities but inorganic ones exist at high concentrations. The addition of 4 g l⁻¹ gelrite as the gelling agent decreased significantly, RGR and RFWG in comparison with 3 g l⁻¹ gelrite (Table S2). Indeed, as a result of the rigidity of the gelling agents, water and nutrient uptake was reduced. Therefore, the growth of callus was reduced. It was reported that gelling agent type and its concentration affect water availability and cytokinin uptake. Furthermore, the chemical and physical characteristics of a culture medium are influenced by both the brand and concentration of the gelling agent.

Increasing the amount of myoinositol to 3 times as compared to the control resulted in the lowest RGR and RFWG with an average of 0.039 d⁻¹ and 1.64, respectively. Subsequently, omission of plant hormones in the medium caused lowest RGR and RFWG with an average of 0.041 d⁻¹ and 1.80, respectively (Table S2). Improving callus growth with increasing amount of myoinositol up to an optimum concentration and decrease in callus growth with concentration beyond the optimum level in Vitis has been reported. No significant difference in callus growth was observed between the control and T22 (supplemented with 2 mg l⁻¹ GA₃) (Table S2). While auxins and cytokinins are required for the growth of tissue cultures, the need for gibberellic acid is controversial.

Since pH of the medium influences the uptake of nutrients by regulating their solubility, the adjustment of the medium pH is necessary. According to the obtained results, MS medium with pH 6.0 is recommended for the production of hazel callus (Table S2). Effect of the medium pH on callus growth of *Aquilaria malaccensis* was reported. No significant difference in hazel callus growth was obtained by replacement of FeEDTA by FeEDDHA, nor by increasing the amount of KNO₃ up to 1.5 times and also using half the amount of NH₄NO₃. Denitrogen plays a major role in growth. The cell growth is affected by the form and amount of nitrogen supply of nitrogen. Doubled amount of NH₄NO₃ as compared to the control reduced callus growth (Table S2). Nitrogen is the major source in culture medium. Maintaining cultured cells in an undifferentiated state requires an easily attainable nitrogen source. Nitrogen plays a major role in growth. The cell growth is affected by the form and amount of nitrogen source in culture medium. Maintaining cultured cells in an undifferentiated state requires an easily attainable nitrogen source. Nitrogen plays a major role in growth. The cell growth is affected by the form and amount of nitrogen source in culture medium. Nitrogen plays a major role in growth. The cell growth is affected by the form and amount of nitrogen source in culture medium. Maintaining cultured cells in an undifferentiated state requires an easily attainable nitrogen source. Nitrogen plays a major role in growth. The cell growth is affected by the form and amount of nitrogen source in culture medium. Maintaining cultured cells in an undifferentiated state requires an easily attainable nitrogen source.

**Effect of casein hydrolysate on growth of hazel callus.** Adding six concentrations of casein hydrolysate (0, 500, 1000, 1500, 2000, 2500 and 3000 mg l⁻¹) to MS medium increased the weight and growth rate of hazel callus (Fig. S1). The highest RGR and RFWG of callus with an average of 0.068 d⁻¹ and 4.44, respectively were obtained by using 1000 mg l⁻¹ of casein hydrolysate in MS medium which was significantly higher than that of the control. It was reported that media supplemented with casein hydrolysate can improve callus growth in different plants. Casein hydrolysates contain calcium, phosphate, microelements, vitamins and up to 18 amino acids. Among commercially available casein hydrolysates, the supplies provided by enzymatic hydrolysis of proteins are considered to be of optimal quality.

**Effect of spirulina powder on growth of hazel callus.** *Arthrospira platensis*, also known as spirulina, is a multicellular and filamentous blue-green microalga. It is an edible microbe with a high food value and provides high levels of vitamins, minerals, β-carotene, essential fatty acids and antioxidants. This investigation on hazel explores the effect of spirulina powder on callus growth rate. Calli were cultured on MS medium supplemented with different concentrations of spirulina powder (0, 100, 500, 1000, 1500 and 2000 mg l⁻¹). The results indicated that spirulina powder in the medium significantly affected hazel callus growth. The highest RGR and RFWG of callus with an average of 0.072 d⁻¹ and 5.03, respectively, were obtained by using 1000 mg l⁻¹ of spirulina powder in MS medium, which was significantly higher than that of the control with a mean of 0.056 d⁻¹ and 3.10, respectively (Fig. S2). The favorable consequence of seaweed extract on growth, yield, quality and environmental
Table 1. Different modified media (based on MS medium) tested for improving hazel callus growth. Volume of medium in all treatments was 70 ml.

| Treatment | Medium pH = 6.0 | Phytage (3 g l⁻¹) | Spirulina powder (1000 g l⁻¹) | Glutamine (50 mg l⁻¹) | Proline (50 mg l⁻¹) | Alanine (50 mg l⁻¹) | Phenylalanine (50 mg l⁻¹) | Cysteine (50 mg l⁻¹) | Methionine (50 mg l⁻¹) | Casein hydrolysate (1000 g l⁻¹) | Glycine (50 mg l⁻¹) | FeEDDHA (96 mg l⁻¹) |

| M₁₀       |                |                   |                           |                      |                  |                  |                     |                     |                     |                       |                  |                 |
| M₁₁       |                |                   |                           |                      |                  |                  |                     |                     |                     |                       |                  |                 |
| M₁₂       |                |                   |                           |                      |                  |                  |                     |                     |                     |                       |                  |                 |
| M₁₃       |                |                   |                           |                      |                  |                  |                     |                     |                     |                       |                  |                 |
| M₁₄       |                |                   |                           |                      |                  |                  |                     |                     |                     |                       |                  |                 |

Effects of amino acids supplementation on growth of hazel callus. The present investigation showed the effects of some amino acids (glutamine, proline, alanine, phenylalanine, cysteine and methionine) at different concentrations (0, 50, 100, 150 and 200 mg l⁻¹) on the growth of hazel callus. As shown in Fig. S3, the supplementation of these amino acids in culture media resulted in additive effects on RGR and RFWG of callus. Results indicated that using MS medium supplemented with any studied concentration of glutamine, alanine or methionine (Fig. S3) improved callus growth, but the maximum RGR and RFWG of callus were obtained by the addition of 50 mg l⁻¹ glutamine, alanine or methionine. MS medium supplemented with any concentration of proline, phenylalanine or cysteine improved callus growth (Fig. S3). No significant difference was observed between different concentrations of proline, phenylalanine or cysteine (Fig. S3). Therefore, the addition of 50 mg l⁻¹ proline, phenylalanine and cysteine to medium is recommended. Increased rate of callus growth by amino acid supplements have been reported²⁰,²¹. Amino acids are an accessible nitrogen source for plant cells and can be absorbed much more readily than inorganic in the same medium²⁵. According to the results of some studies²³,²⁴, amino acids are not necessary ingredient for many cultural purposes but their addition to the medium can compensate for medium deficiency or provide an accessible source of nitrogen to cultured cells or tissues. With ammonium ion uptake, plant tissues use adenosine triphosphate (ATP) as an energy source to convert it into amino acids. Therefore, the presence of suitable amino acids in the medium may save some ATPs.

Optimized culture medium for callus growth of hazel. According to the results obtained in the preliminary experiments, some treatments including 3 g l⁻¹ gelrite as the gelling agent, medium pH 6.0, the use of 70 ml of medium instead of 50 ml and the addition of 1000 mg l⁻¹ of casein hydrolysate, 1000 mg l⁻¹ of spirulina powder, 50 mg l⁻¹ of glutamine, proline, alanine, phenylalanine, cysteine and methionine, improved hazel callus growth. Thus, in order to find the optimal culture medium for improvement of hazel callus growth, 14 new modified MS media were prepared and investigated in another study (Table 1). In this final experiment, five grams of callus were cultured in each replication and the data was analyzed after 35 days.

The results presented in Table 2, clearly show that the new modified MS medium, M₁₀, resulted in the highest amount of fresh weight (63.06 g), dry weight (1.70 g), RGR (0.072 d⁻¹) and RFWG of callus of the major amino acids. It is thought that casein hydrolysate might contain some unknown growth promoting factors. Data shown in Table 2 indicated that M₁₂ medium (M₁₀ medium supplemented with FeEDDHA) reduced callus growth as compared to M₁₀ medium. As shown in Fig. S4, culture medium was not consumed by the hazel callus. It seems that the absorption and transport of nutrient elements are impaired in this modified MS medium.
Effect of optimized M10 medium on fatty acids profile of hazel callus. The seed oil of *C. avellana* and *C. americana* can be served as occlusive skin-conditioning agents. Nut oil of *C. avellana* was reported as a natural cosmetic hazel oil without contaminants, which is used in 85 cosmetic formulations. Analysis of *C. avellana* fatty acids profile indicated that linoleic acid (C18:2) in M0 medium and the linoleic acid (C18:2) and oleic acid (C18:1) in M10 medium were the main fatty acids in the fatty acids profile (Fig. 2). The proportion of unsaturated fatty acids was higher than the saturated acids. Palmitic acid (C16:0) and linoleic acid (C18:2) were the major components of saturated and unsaturated fatty acids, respectively. Short (myristic acid, C14:0) and long chain fatty acids (arachidic acid, C20:0) were detected in small amounts. Arachidonic acid (C20:4) was detected only in M10. Unsaturated, saturated and total fatty acids of callus in M10 were higher than in M0 according to Student’s t-test.

Effect of optimized M10 medium on cell growth and paclitaxel production in hazel cell suspension culture. Growth trends of the hazel cell suspensions showed that cell growth in M10 reached the stationary phase 2 days later as compared to the control (Fig. 3). The maximum dry weight in the control and M10 were about 11.39 and 13.64 g l\(^{-1}\), respectively (Fig. 3). The average growth rate over the growth period (AGR = [maximum cell density – initial cell density]/growth period) was about 0.50 and 0.56 g l\(^{-1}\) day\(^{-1}\) in the control and M10, respectively. The cell growth index (maximum cell density/initial cell density) in the control and M10 were about 8.78 and 10.49, respectively. The maximum biomass in M10 was 19.8% greater than that in the control.

| Treatment  | FW (g) | DW (g) | RGR (g day\(^{-1}\)) | RFWG (g) | PCWC (%) |
|------------|--------|--------|----------------------|---------|---------|
| M0         | 40.48  | 1.06   | 0.0597               | 7.10    | 97.37   |

Table 2. Effects of different modified MS media on fresh weight (FW), dry weight (DW), relative growth rate (RGR), relative fresh weight (RFWG) and percentage of callus water content of hazel callus (PCWC). Means within a column followed by the same letter are not significantly different (p ≤ 0.05).
was considered that this higher biomass was achieved by higher average growth rate and also by maintaining growth over a longer period of time (Fig. 3).

The average growth rate of M10 was higher than that of the control and the hazel cells grown in M10 medium were able to maintain positive growth during a period of 22 days, whereas the cells grown in the control reached stationary phase within 21 days. These trends may be explained by the amendments used for M10 medium including major and minor nutrients, carbohydrates, amino acids and plant growth promoting substances present in spirulina powder and casein hydrolysate that were absent in the control. The maximum total yield of paclitaxel concentration in the control (77.7 µg l⁻¹) and M10 medium (106.6 µg l⁻¹) was obtained on days 21 and 23, respectively and was produced mainly in the cells (Fig. 4). The dry weight of cells and the intracellular, extracellular and total yield of paclitaxel increased significantly by using M10 medium according to Student’s t-test (Table S3).
Conclusion

Paclitaxel production by *C. avellana* cell culture was found for the first time in 2006 and the use of hazel cell culture for paclitaxel production is promising. Establishment of fast-growing *in vitro* cultures by using the most suitable medium is a key step towards producing paclitaxel from the hazel cell cultures. However, there are no considerable reports regarding the influences of different nutrient concentrations in the culture medium on callus growth of *C. avellana*. Therefore, the effects of different concentrations of mineral elements, spirulina powder, casein hydrolysate and some amino acids in MS medium on improvement of the production of hazel callus, was investigated. The modified MS medium (pH 6.0) with 1000 mg l\(^{-1}\) algae powder, 1000 mg l\(^{-1}\) casein hydrolysate and 3 g l\(^{-1}\) gelrite favored the increase of callus biomass of *C. avellana*. M\(_{10}\) medium as the best treatment increased the fatty acids yield of hazel callus (66.7%) as compared to the control. Also, M\(_{10}\) liquid medium increased the culture period and cell biomass in cell suspension culture. Production of paclitaxel by hazel cell suspension was not as high as that reported for *Taxus* cell suspension. However, it should be noted that establishment of the fast-growing *in vitro* culture of hazel may compensate for the lower yield of paclitaxel. It is noteworthy that paclitaxel production in this cell clone was improved by the combined use of phenylalanine and Vanadyl sulfate. Therefore, it is recommended to improve paclitaxel productivity in two stage cell culture system. The use of M\(_{10}\) liquid medium may favour increase of cell population by improving growth at the first stage of culture (logarithmic phase). Besides, the use of different elicitors and precursors at the second stage (stationary phase) can lead to increased production of paclitaxel via involvement of some related pathways. Also, the lipids of hazel callus may have large clinical and economic applications due to their content of unsaturated fatty acids (linoleic and oleic acids) that are used in cosmetic and pharmaceutical products. The cell suspension of *C. avellana* as a promising source of paclitaxel can be effective in reducing the high cost of drug-therapy.

Materials and Methods

Plant materials and tissue culture reagents. The *C. avellana* callus was obtained from a stable 6-year-old diploid callus. Concisely, callus were derived from seed cotyledons on MS medium supplemented with 0.2 mg l\(^{-1}\) 6-benzylaminopurine and 2 mg l\(^{-1}\) dichlorophenoxyacetic acid, and solidified with 8 g l\(^{-1}\) agar agar. The pH of all media was adjusted to 5.8 with either KOH or HCl prior to autoclaving for 20 min at 121 °C. All cultures were incubated in dark at 25 ± 2 °C until the calli emerged. These calli were routinely subcultured every 25 days. To obtain a homogenous callus, several subcultures of calli were carried out on the same medium.

The medium components, plant growth regulators, paclitaxel and fatty acids standards used in the experiments were supplied by Sigma and Merck Chemical Companies.

Culture amendment experiments. Nine independent experiments with five replications were carried out in this research. All experiments except the first one were planned based on Completely Randomized Design (CRD), and the first experiment was set up in a Randomized Complete Block Design (RCBD). In all experiments, each replication consisted of a glass jar with autoclave-resistant plastic caps (5.5 cm in diameter, 8 cm in height and 250 ml in volume) containing 50 ml medium and seven grams of hazel callus. The cultures were incubated in a controlled incubator at 25 °C for 25 days in the dark. The first experiment was set up to test effects of 22 modifications applied in MS medium (Table S1) for improvement of hazel callus growth.

The second experiment was performed to assess the effects of different concentrations of casein hydrolysate (0, 500, 1000, 1500, 2000, 2500 and 3000 mg l\(^{-1}\)) on callus growth of *C. avellana*. The third experiment was designed to study the effect of spirulina (*Arthrospira platensis*) powder in medium (0, 100, 500, 1000, 1500 and 2000 mg l\(^{-1}\)) on the fresh and dry weights of hazel calli. The next six independent experiments were planned to evaluate separately, the effects of different levels (0, 50, 100, 150 and 200 mg l\(^{-1}\)) of six amino acids (glutamine, proline, alanine, phenylalanine, cysteine and methionine) on callus growth of *C. avellana*.

Growth indices and water content of callus. In all the experiments, two growth indices and water content of callus were investigated as follows:

Relative growth rate (day\(^{-1}\)). Calli were weighted before culturing on callus production medium and were weighted once again 25 days after culture (W1). Relative growth rate (RGR) was calculated based on fresh weight according to Eq. (1)\(^{52}\).

\[
\text{RGR(} \text{day}^{-1} \text{)} = \frac{\ln(W_1) - \ln(W_0)}{\text{growth period}} \tag{1}
\]

Relative fresh weight growth (RFWG). Relative fresh weight growth of callus was calculated according to Eq. (2).

\[
\text{RFWG} = \frac{(W_1 - W_0)}{W_0} \tag{2}
\]

Percentage of callus water content (PCWC). All samples of calli were dried to constant weight at 60 °C for 36 h in an oven. This trait was calculated according to Eq. (3).

\[
\text{PCWC} = \frac{[(\text{Freshweight} - \text{Dryweight})/\text{Freshweight}] \times 100} \tag{3}
\]

Lipid analysis. Calli were dried in the oven at 60 °C. Lipid extraction, preparation of the fatty acid methyl esters and GC/MS analysis for *C. avellana* callus was done according to the procedure described by Bao et al\(^{53}\). All samples were filtered through 0.22 μm cellulose acetate syringe filters before analysis with GC/MS. The fatty acids
in samples were analyzed by Hewlett Packard 5890 gas chromatograph MSD 5972 mass analyzer with a HP-5MS capillary column (Agilent Technologies, Santa Clara, CA).

**Measurement of cell growth.** The *C. avellana* cell suspension cultures were obtained by cultivating 5 g callus into 250 ml Erlenmeyer flask containing 100 ml of MS medium supplemented with 0.2 mg l⁻¹ BAP and 2 mg l⁻¹ 2,4-D acid and maintained at 25 °C in darkness on gyratory shakers at 110 rpm. Cell suspensions were also subcultured every 15 days until the cells reached homogeneity. Then, 1.5 ± 0.1 g of cells (fresh mass) were cultivated in 100 ml Erlenmeyer flask containing 30 ml MS medium. The cell growth was determined by measuring the dry cell weight (DCW). Briefly, the biomass in the cell suspension culture was separated from the liquid medium by filtration (Whatman No. 1) and then dried at 60 °C to constant weight to obtain the dry cell weight.

**Quantification of paclitaxel.** Hazel cells were separated from cell suspension culture through a filter paper (Whatman No. 1). The cell-free medium was subsequently extracted according to the method proposed by Fett-Neto et al. Intracellular paclitaxel was extracted from the cells with a procedure described by Luo et al. All samples were filtered through 0.22 μm cellulose acetate syringe filters before analysis with HPLC. Paclitaxel in samples was analyzed by HPLC (Waters, USA) with a C18 analysis column (Macherey-Nagel EC 250/4.6 Nucleodur). The sample (20 μl) was injected each time and detected at 230 nm using a UV detector. The mobile phase was methanol: water (80:20 v/v) at a flow rate of 1.0 ml/min. The quantification of paclitaxel was based on an external standard of genuine paclitaxel (Sigma).

**Statistical analysis.** The hypothesis of normality and equal variance were met and conventional parametric statistics was used for the analysis. Analysis of variance and means comparison using least significant difference (LSD) were performed by SAS (SAS 9.1, 2003) and Excel (Excel, 2013) software was used for making graphs.

**Availability of data and material.** The dataset supporting the conclusions of this article is included in the article.
