Invariants of $C^{1/2}$ in terms of the invariants of $C$

Andrew N. Norris

Mechanical and Aerospace Engineering, Rutgers University, Piscataway NJ 08854-8058, USA norris@rutgers.edu

Abstract

The three invariants of $C^{1/2}$ are key to expressing this tensor and its inverse as a polynomial in $C$. Simple and symmetric expressions are presented connecting the two sets of invariants $\{I_1, I_2, I_3\}$ and $\{i_1, i_2, i_3\}$ of $C$ and $C^{1/2}$, respectively. The first result is a bivariate function relating $I_1, I_2$ to $i_1, i_2$. The functional form of $i_1$ is the same as that of $i_2$ when the roles of the $C$-invariants are reversed. The second result expresses the invariants using a single function call. The two sets of expressions emphasize symmetries in the relations among these four invariants.

1 Introduction

We consider relations among the basic tensors of three dimensional continuum mechanics, all defined by the deformation $F$,

$$F = RU = VR, \quad C = F^t F, \quad B = FF^t.$$  

$U$ and $V$ are symmetric and positive definite, and therefore

$$U = C^{1/2}, \quad V = B^{1/2}.$$  

Here we will only consider properties of $U$ and $C$, but the results apply to $V$ and $B$.

Although the square root of a second order positive definite symmetric tensor is unique and unambiguous it is not, however, a simple algebraic construct. One way to circumvent this problem is to express $U$ as a polynomial in $C$ using the Cayley-Hamilton equation,

$$U^3 - i_1 U^2 + i_2 U - i_3 I = 0. \quad (1)$$

Here $i_1, i_2, i_3$ are the invariants of $U$,

$$i_1 = \text{tr } U, \quad i_2 = \frac{1}{2}(\text{tr } U)^2 - \frac{1}{2} \text{tr } U^2, \quad i_3 = \text{det } U,$$

Multiply $(1)$ by $(U + i_1 I)$, and note that the result contains terms proportional to $I, U, U^2$ and $U^3$. Replacing the latter two by $C$ and $C^2$ gives Ting (1985)

$$U = (i_1i_2 - i_3)^{-1}(i_1i_3 I + (i_1^2 - i_2) C - C^2). \quad (2)$$
Note that \( i_1 i_2 - i_3 = \det(i_1 \mathbf{I} - \mathbf{U}) > 0 \) (Carroll, 2004). The inverse \( \mathbf{U}^{-1} \) may be obtained by multiplying each side of (2) with \( \mathbf{C}^{-1} \) and using the Cayley-Hamilton equation for \( \mathbf{C} \) to eliminate the single remaining \( \mathbf{C}^{-1} \) term. The orthogonal rotation tensor follows as \( \mathbf{R} = \mathbf{F} \mathbf{U}^{-1} \), from which one can determine kinematic quantities such as the rotation angle and the axis of rotation (Guan-Suo, 1998).

The relation (2) for \( \mathbf{U} \) in terms of \( \mathbf{C} \) avoids the tensor square root difficulty but introduces another: how to express \( \{i_1, i_2, i_3\} \) in terms of \( \mathbf{C} \), or more specifically in terms of its invariants,

\[
I_1 = \text{tr} \mathbf{C}, \quad I_2 = \frac{1}{2} (\text{tr} \mathbf{C})^2 - \frac{1}{2} \text{tr} \mathbf{C}^2, \quad I_3 = \det \mathbf{C}.
\]

While the relation \( i_3 = \sqrt{I_3} \) is simple, formulas for \( i_1 \) and \( i_2 \) are not. But as eq. (2) and related identities illustrate, the functional relations between the two sets of invariants are important for obtaining semi-explicit expressions for stretch and rotation tensors, and for their derivatives (Hoger and Carlson, 1984a; Steigmann, 2002; Carroll, 2004).

The first such relations are due to Hoger and Carlson (1984b) who derived expressions for \( \{i_1, i_2\} \) by solving a quartic equation. Sawyers (1986) subsequently showed that one can obtain alternative relations using the standard solutions (Goddard and Ledniczky, 1997) for the cubic equation of the eigenvalue of \( \mathbf{U} \). Let \( \lambda_1, \lambda_2, \lambda_3 \) be the (necessarily positive) eigenvalues of \( \mathbf{U} \), then the eigenvalues of \( \mathbf{C} \) are \( \lambda_1^2, \lambda_2^2, \lambda_3^2 \), and

\[
\begin{align*}
i_1 &= \lambda_1 + \lambda_2 + \lambda_3, \\
i_2 &= \lambda_1 \lambda_2 + \lambda_2 \lambda_3 + \lambda_3 \lambda_1, \\
i_3 &= \lambda_1 \lambda_2 \lambda_3,
\end{align*}
\]

(3a)

\[
\begin{align*}
I_1 &= \lambda_1^2 + \lambda_2^2 + \lambda_3^2, \\
I_2 &= \lambda_1^2 \lambda_2^2 + \lambda_2^2 \lambda_3^2 + \lambda_3^2 \lambda_1^2, \\
I_3 &= \lambda_1^2 \lambda_2^2 \lambda_3^2.
\end{align*}
\]

(3b)

Sawyers’ approach is to essentially compute the eigenvalues of \( \mathbf{C} \), take their square roots and from these determine the invariants of \( \mathbf{U} \) by (3a). Jog (2006) generalized this scheme to tensors of order \( n > 3 \). This method does not provide direct relations between the invariants. Although the formulas of Hoger and Carlson (1984b) and of Sawyers (1986) are explicit, they are not totally satisfactory. In each case the functional forms are complicated. As we will see, there is no way to avoid this “complexity” since we are dealing with roots of cubic and quartic equations. But that is not the basic issue, rather it is a lack of any underlying symmetry or balance in the solutions of Hoger and Carlson (1984b) and of Sawyers (1986). This makes it difficult to comprehend the formulas, and to place them in context. It is all the more unsettling by virtue of the fact that the formulas are associated with algebraic systems of deformation tensors, systems that are elegant and generally quite transparent.

The object of this paper is to express \( \{i_1, i_2, i_3\} \) in terms of \( \{I_1, I_2, I_3\} \) in two forms that each display the underlying symmetry of the relations. Both forms employ a single function, but have slightly different properties. We begin in section 2 with a summary of the principal results, followed by a review of the previously known solutions in section 3. The new formulas for the invariants of \( \mathbf{C}^{1/2} \) are derived in section 4, with some closing comments in section 5.

## 2 Principal results

The first result is

...
Theorem 1  The invariants of \( C^{1/2} \) are

\[
i_1 = I_3^{1/6} f \left( \frac{I_1}{I_3^{1/3}}, \frac{I_2}{I_3^{2/3}} \right), \quad i_2 = I_3^{1/3} f \left( \frac{I_2}{I_3^{2/3}}, \frac{I_1}{I_3^{1/3}} \right), \quad i_3 = I_3^{1/2}, \tag{4}\]

where \( f \) is a function of two variables,

\[
f(x, y) = g(x, y) + \sqrt{x - g^2(x, y)} + 2/g(x, y), \tag{5a}\]

\[
g(x, y) = \left( \frac{1}{3} \left( x + \sqrt{x^2 - 3y \left( (\zeta + \sqrt{\zeta^2 - 1})^{1/3} + (\zeta - \sqrt{\zeta^2 - 1})^{1/3} ) \right) \right) \right)^{1/2}, \tag{5b}\]

\[
\zeta = \frac{27 + 2x^3 - 9xy}{2(x^2 - 3y)^{3/2}}. \tag{5c}\]

The function \( g \) can be expressed in the alternate form

\[
g(x, y) = \sqrt{\frac{1}{3} \left( x + 2\sqrt{x^2 - 3y \cos \left( \frac{1}{3} \arccos(\zeta(x, y)) \right) \right)}\right].
\]

It is clear from Theorem 1 that the following reduced quantities are the important variables:

\[
j_1 = \frac{i_1}{I_3^{1/3}}, \quad j_2 = \frac{i_2}{I_3^{2/3}}, \tag{6a}\]

\[
J_1 = \frac{I_1}{I_3^{1/3}}, \quad J_2 = \frac{I_2}{I_3^{2/3}}, \tag{6b}\]

in terms of which the Theorem states

\[
j_1 = f(J_1, J_2), \quad j_2 = f(J_2, J_1).
\]

Alternatively, the sum and difference of reduced invariants may be considered as the key parameters, which is evident from:

Lemma 1  The following relation holds between the invariants of \( C \) and \( C^{1/2} \):

\[
\frac{J_1 - J_2}{j_1 - j_2} = j_1 + j_2 + 2. \tag{7}\]

An immediate consequence of Lemma 1 is that we need only determine \( j_1 + j_2 \) or \( j_1 - j_2 \) since the other follows directly from (7). For instance, we could calculate \( j_1 + j_2 = f(J_1, J_2) + f(J_2, J_1) \), but this requires evaluation of \( f \) twice, and it does not reveal the underlying symmetry of the arguments. The second result is a simpler relation between the invariants, one that uses a single call to the function \( f \):

Theorem 2  The reduced invariants of \( C^{1/2} \) and \( C \) are connected by

\[
\begin{align*}
\hat{j}_1 &= \frac{s}{2} + \frac{J_1 - J_2}{2s + 4}, \tag{8a} \\
\hat{j}_2 &= \frac{s}{2} - \frac{J_1 - J_2}{2s + 4}, \tag{8b} \\
s &= F(J_1, J_2), \tag{8c}
\end{align*}
\]

where

\[
F(x, y) = (2 + x + y)^{1/3} f \left( \frac{6 + x + y}{(2 + x + y)^{2/3}}, \frac{9 + 5x + 5y + xy}{(2 + x + y)^{4/3}} \right). \tag{9}\]
Thus, \( j_1 + j_2 = F(J_1, J_2) \) and \( F \) is a symmetric function of its arguments, \( F(x, y) = F(y, x) \). Also, \( F \) provides an alternative expression for the function \( f \):

\[
f(x, y) = \frac{1}{2}F(x, y) + \frac{x - y}{2F(x, y) + 4}.
\]

This form for \( f \) employs the function itself, but evaluated at different arguments. This is a property of the nonlinear nature of the function.

3 The methods of Hoger and Carlson and of Sawyers

Starting from the identities (3) it may be easily verified that (Hoger and Carlson, 1984b)

\[
i_1^2 - 2i_2 = I_1, \quad i_2^2 - 2i_1i_3 = I_2, \quad i_3^2 = I_3.
\]

(10)

The last implies \( i_3 = I_3^{1/2} \). It remains to find \( i_1 \) and \( i_2 \).

Hoger and Carlson (1984b) eliminated \( i_2 \) between eqs. (10)1 and (10)2, to obtain a quartic equation in \( i \), which they then solved. The same solution for \( i \) is obtained more directly by starting with the ansatz

\[
i_i = \lambda + \rho,
\]

(11)

where \( \lambda \) is any one of the triplet \( \{\lambda_1, \lambda_2, \lambda_3\} \). For instance, if \( \lambda = \lambda_1 \) then \( \rho = \lambda_2 + \lambda_3 \) and \( i_2 = \lambda_1(\lambda_2 + \lambda_3) + \lambda_2\lambda_3 \) is

\[
i_2 = \rho \lambda + i_3/\lambda.
\]

(12)

This holds no matter which value \( \lambda \) takes. Substituting from (11) into (10)1 implies

\[
\rho^2 = I_1 - \lambda^2 + 2i_3/\lambda.
\]

(13)

The right member is necessarily positive, and using \( i_3 = I_3^{1/2} \) we can therefore express \( \rho > 0 \) in terms of \( I_1, I_3 \) and \( \lambda \).

In summary,

\[
i_1 = \lambda + \sqrt{I_1 - \lambda^2 + 2\sqrt{I_3}/\lambda},
\]

(14a)

\[
i_2 = \sqrt{I_3}/\lambda + \sqrt{I_1\lambda^2 - \lambda^4 + 2I_3\lambda},
\]

(14b)

\[
i_3 = \sqrt{I_3},
\]

(14c)

where \( \lambda \) is any positive root of the characteristic equation of \( C \),

\[
\lambda^6 - I_1\lambda^4 + I_2\lambda^2 - I_3 = 0.
\]

(15)

For instance,

\[
\lambda = \left( \frac{1}{3}(I_1 + [\xi + \sqrt{\xi^2 - (I_1^2 - 3I_2)^3}]^{1/3} + [\xi - \sqrt{\xi^2 - (I_1^2 - 3I_2)^3}]^{1/3}) \right)^{1/2},
\]

and

\[
\xi = \frac{1}{2}(2I_1^3 - 9I_1I_2 + 27I_3).
\]
Note that we assumed that $\lambda$ in the ansatz (11) and (12) is a root of eq. (15), but this is actually a requirement, as can be seen from eqs. (10) using (11) - (13). Equations (11) and (12) represent a standard method of reducing a quartic to a cubic equation.

Equation (14a) is essentially the same as the first relation in (11) - (13) of (Hoger and Carlson, 1984b, eq. (5.5)), although they did not identify the root of the cubic explicitly. Hoger and Carlson (1984b) recommended using (10) to obtain $i_2$. The relation (14b) is quite different and is suggestive of the symmetry underlying the solutions for $i_1$ and $i_2$ that is evident in Theorem 1. We discuss this further in the next section from a different perspective.

It is interesting to compare this with the explicit positive solution of (15) provided by Guan-Suo (1998), based on Sawyers (1986). Starting with the characteristic equation for $U$,

$$\lambda^3 - i_1\lambda^2 + i_2\lambda - i_3 = 0,$$

combined with eqs. (10) and (10), this becomes a quadratic equation for $i_2$. The solution is (Guan-Suo, 1998, p. 199)

$$i_2 = \lambda^{-1}\left(\sqrt{T_3} + \sqrt{2\sqrt{T_3}\lambda^3 + I_2\lambda^2 - I_3}\right).$$

This appears to be different than eq. (14b), but they are equivalent when one takes into account that $\lambda$ satisfies eq. (15).

In short, Hoger and Carlson (1984b) and Sawyers (1986) derived eqs. (14a) and (14b), respectively. They did not however, note the symmetry between the formulas, which is one of the central themes in this paper: that a single function determines both $i_1$ and $i_2$. In the next section we complete the proof of Theorem 1.

### 4 An alternative approach

The three conditions in (10) can be combined into a single polynomial identity,

$$(1 - i_2z^2)^2 + (i_1z - i_3z^3)^2 = 1 + I_1z^2 + I_2z^4 + I_3z^6, \quad \forall z \in \mathbb{C}.$$ 

Using the reduced variables of (15), this becomes

$$(1 - j_2z^2)^2 + (j_1z - z^3)^2 = 1 + J_1z^2 + J_2z^4 + z^6, \quad \forall z \in \mathbb{C}.$$ 

Comparing coefficients implies the pair of coupled equations

$$j_1^2 - 2j_2 = J_1, \quad (17a)$$

$$j_2^2 - 2j_1 = J_2. \quad (17b)$$

Thus, solutions must be of the form

$$j_1 = f(J_1, J_2), \quad j_2 = f(J_2, J_1),$$

for some function $f(x, y)$ which satisfies

$$f^2(x, y) - 2f(y, x) - x = 0. \quad (18)$$

It should be noted that the second relation in their eq. (5.5) never applies. That is, it can be shown that the possible equality cannot occur.
This is the fundamental equation for \( f(x, y) \). It implies the dual relation

\[
f^2(y, x) - 2f(x, y) - y = 0. \tag{19}
\]

Eliminating \( f(y, x) \) between eqs. (18) and (19) leads to a quartic in \( f = f(x, y) \):

\[
(f^2 - x)^2 - 8f - 4y = 0. \tag{20}
\]

This is equivalent to the quartic of Hoger and Carlson (1984b) but expressed in the reduced variables. We have already derived a solution of the quartic in the previous section by using the ansatz (11) based on a root of the cubic equation (15). Equation (14a) therefore defines the function \( f \), which can be read off by converting to the reduced variables \( j_1, j_2, J_1, J_2 \). It may be easily verified that the function of eq. (5) results.

But what about the relation (14b) for \( i_2 \)? It does not seem to convert into the expression claimed in Theorem 1, i.e. \( j_2 = f(J_2, J_1) \). Rather, using eq. (14b) and \( j_2 = f(J_2, J_1) \) to define \( f \) we obtain a different expression for \( f \):

\[
f(y, x) = \frac{1}{g(x, y)} + \sqrt{x - g^2(x, y) + 2/g(x, y) g(x, y)}. \tag{21}
\]

This is in fact consistent with the definition of \( f \) in Theorem 1 because \( g(x, y) \) satisfies the normalized version of eq. (16),

\[
g^3(x, y) - f(x, y)g^2(x, y) + f(y, x)g(x, y) - 1 = 0. \tag{22}
\]

Using this and the expression for \( f(x, y) \) in (5), gives eq. (21). This completes the proof of Theorem 1.

It is interesting to note from (22) that \( 1/g(y, x) \) satisfies the same equations as \( g(x, y) \), i.e.

\[
g^{-3}(y, x) - f(x, y)g^{-2}(y, x) + f(y, x)g^{-1}(y, x) - 1 = 0.
\]

But this does not mean that \( g(y, x) \) equals \( 1/g(x, y) \), since they can (and do) correspond to different roots of the cubic.

The identity (7) of Lemma (1) follows from the coupled equations (17), and the details of the proof of Theorem 2 are in the appendix.

5 Conclusion

Although the expressions for \( i_1 \) and \( i_2 \) involve the roots of the characteristic cubic equation of \( C \), it seems that the governing quartic equation (20) is more fundamental. This is the equation that defines the functions \( f \) and \( F \) of Theorems 1 and 2. In fact \( F \) is defined by \( f \), which is in some ways the central function involved. It is interesting that the quartic equation first considered by Hoger and Carlson (1984b) reappears in this manner.

Which of the expressions for \( i_1 \) and \( i_2 \) are actually best in practice? While the expressions (8) are perhaps the most aesthetically pleasing in form, eq. (4) is probably simpler to implement. The final choice is of course left to the reader.
Appendix

A Proof of Theorem 2

For simplicity of notation, let \( f \) and \( f' \) denote \( f(x, y) \) and \( f(y, x) \), respectively. Then the coupled equations (18) and (19) are

\[
\begin{align*}
f^2 - 2f' &= x, \\
f'^2 - 2f &= y.
\end{align*}
\]

Adding and subtracting yields, respectively,

\[
\begin{align*}
(f + f' - 1)^2 &= 1 + x + y + 2ff', \\
(f - f')(f + f' + 2) &= x - y,
\end{align*}
\]

which in turn imply

\[
\begin{align*}
f + f' &= F, \\
f - f' &= x - y
\end{align*}
\]

where

\[ F = 1 + \sqrt{1 + x + y + 2ff'}. \]

The function \( F = F(x, y) \) is clearly a symmetric function of \( x \) and \( y \), i.e., it is unchanged if the arguments are switched. Solving eqs. (A.3) gives

\[
\begin{align*}
f &= \frac{F}{2} + \frac{x - y}{2F + 4}, \\
f' &= \frac{F}{2} - \frac{x - y}{2F + 4}.
\end{align*}
\]

Although the formulas (A.4) clearly split \( f \) into parts that are symmetric and asymmetric in the two arguments, they are not explicit since the function \( F \) involves the product \( ff' \). Taking the product of the two expressions in (A.4) leads to an equation for \( ff' \). It is simpler to consider the equation for \( F \), which after some manipulation may be reduced to the quartic:

\[
[F^2 - (6 + x + y)]^2 - 8(2 + x + y)F - 4[(5 + x)(5 + y) - 16] = 0.
\]

Let

\[ F = (2 + x + y)^{1/3} u, \]

then \( u \) satisfies

\[
(u^2 - X)^2 - 8u - 4Y = 0,
\]

where

\[
X = \frac{6 + x + y}{(2 + x + y)^{2/3}}, \quad Y = \frac{9 + 5x + 5y + xy}{(2 + x + y)^{4/3}}.
\]

Equation (A.5) is the same as the quartic (20) satisfied by \( f \), but with \( X \) and \( Y \) instead of \( x \) and \( y \). Thus,

\[ u = f(X, Y), \]

which completes the proof of Theorem 2.
