Abstract
Tomato is well known for its quality and nutritional value all over the world but untimely and imbalanced fertilizer application has a severe effect on yield & quality of tomato. To investigate the effect of specific timing of fertilizer application for off-season tomato (Sahel hybrid), a study was conducted at Nuclear Institute for Food and Agriculture (NIFA), Peshawar. Nitrogen, phosphorus and potassium (NPK) fertilizers were applied at the rate of 10-10-15 kg ha⁻¹ at 7, 14 and 21 days intervals, starting after establishment of crop (30 days after transplanting) till mid of June. The current study was carried out under randomized complete block (RCB) design having three replicates of four treatments. The maximum fruit yield (2.94 t/10 Marla tunnel) was recorded in the treatment receiving NPK @ 10-10-15 kg ha⁻¹ at 7 days interval that was significantly (P<0.05) higher as compared to those fertilized at 14 days (1.75 t/10 Marla tunnel) and 21 days (0.83 t/10 Marla tunnel) intervals, while minimum (0.5 t/10 Marlas) was recorded in control. Maximum grade-A tomatoes having above 100 g weight per fruit (62%), density (1.30 g/cm³), chlorophyll content / SPAD value (57.63), total acidity (0.44%), protein content (15.4%), total soluble solids (5.4 °Brix), N (1.25%), P (0.20%), K (1.45%) in fruit and improved shelf-life (9 days) were recorded with the NPK application at 7 days intervals. The concentration of vitamin C showed increasing trend along with decrease in N dose at all application times. This study suggested that application of timely and balanced fertilizer may be a good strategy to get higher and good quality yield of off-seasonally grown tomatoes in the tunnels.

Introduction
Tomato (Lycopersicum esculentum), widely used as a salad as well as in cooking all over the world, is an important vegetable. It is a nutritious vegetable having high contents of Na, K, iron, vitamins A & C and many antioxidants like lycopene [1]. During 2016, the tomato was cultivated on about an area of 4.85 million hectares, from which around 176.85 million tonnes production was achieved. Pakistan is the 35th largest country in the world with respect to tomato production [2]. During 2016-17, total tomato production in Pakistan was recorded 601.098 thousand tones from the cultivated area of 63.2 thousand hectares [3]. The largest
tomato producer province was Baluchistan followed by Sindh, KP and Punjab [4]. Contrary to the recent past, nutrition is being considered as an integral part of food security [5]. Accordingly, all four dimensions of food security, viz. the accessibility, availability, stability and utilization of macro and micronutrients are deemed components of food security [6]. Subsequent to this, a focus on the role of small producers in the agriculture sector is an important element. Production of off-season vegetables under high tunnels is an expanding opportunity to enhance food production of the country. High tunnel farming techniques are used to produce off-season vegetables such as tomatoes, cucumbers, chilies, sweet peppers, egg plants and gourds. Similarly, high tunnels have a wide range of advantages like yield and quality enhancement, avoiding the adverse environmental conditions, early crop production aiming at achieving high market value, etc. [7]. Tomato, one of the vital and widely cultivated high tunnel vegetables, possesses a wide range of vital compounds including solid & insoluble solids (5-7%), water (about 90%), carotenoids, citric acid, phenols, flavonoids, vitamins and minerals [8]. It also contains remarkable amounts of lycopene, antioxidants and carotene that play an important role in preventing cancer of many types [9]. However, the ultimate goal is to enhance quality production of tomatoes in high tunnels while improving fertilizer use efficiency and enhancing the socio-economic status of subsistence-level growers and small land-holders.

Nutrient management plays a significant role in enhancing production whether it is applied in open fields or while growing off-season vegetables. Nitrogen, phosphorus and potassium application in the form of organic and inorganic sources at critical growth stages (flowering, fruit setting and fruit development) of the tomato has been reported to enhance their growth and development. For example, N requirement of tomatoes is moderate during foliage growth, until fruit development. P is very important for vigorous growth and fruit production. Likewise, K is needed for fruit development and enlargement [10]. However, USDA (United States Department of Agriculture) together with the Fertilizer Institute promotes a specific framework called 4R nutrient stewardship (4Rs) that aims at increasing productivity and profitability for growers in both highly intensive agricultural systems and subsistence-level growers. The first 2Rs (right source and right rate) are commonly followed during crop production in Pakistan. However, the other 2Rs (right time and right place) are reported to be rarely practiced by farming communities, which results in low nutrient use efficiency and low economic returns [3,5]. The core objectives of the current study were to assess the suitable time interval (right time) for NPK application on yield and quality parameters of F1 hybrid “Sahel” tomatoes grown in high tunnel.

**Materials and Methods**

The study was planned in a high tunnel measuring 28 ft. x 120 ft. with 11 ft. high bend fitted with a polyethylene plastic and 6 ft. roll-up sides at Nuclear Institute for Food and Agriculture (NIFA), Peshawar. The experiment was laid out in randomized complete block (RCB) design having three replicates of four treatments. The treatments consisted of different time intervals for the application of NPK to the tomato crop. A nursery of the F1 hybrid tomato cultivar “Sahel” was raised in plastic tubes (6 cm x 4 cm). After thirty days of germination, the nursery was transferred to tunnel. The soil of experimental tunnel was silt loam, alkaline in nature and non-saline. The soil was marginal in terms of the contents of organic matter (OM), P, K and adequate with respect to potassium (K2O) (Table 1). The spacing between plants and rows were maintained at 1.5 ft. and 3.0 ft. respectively. After thirty
days of germination, the nursery was transferred into the tunnel. Upon establishment of crop about one month after transplanting, NPK @ 10-10-15 kg/ha was applied at 7 days intervals (T1: high dose), 14 days intervals (T2: medium dose) and 21 days intervals (T3: low dose) during the whole season. All the three doses were compared with control (T0: no fertilizer). The experiment was properly maintained following standard cultural practices as commonly observed in high tunnel farming. Tomato fruit yield in each treatment was collected at each harvest and weighed in kilograms (kg). The total yield per treatment was calculated by adding the yields at all harvests for the same treatment.

Fruit and straw samples were washed initially with tap water and then with distilled water. After washing, these samples were firstly air-dried and then oven-dried at 70 °C till constant weight. All these samples were then subjected to grinding in a stainless steel grinder. Soil samples collected at depths of 0-15 cm and 15-30 cm from different places in the tunnel were mixed to make composite samples. Stones and plant residues were removed from these samples and then the samples were dried in the laboratory. The soil samples were then ground and sieved through 2 mm sieve. After labeling, the soil samples were stored in plastic containers. These soil samples were analyzed in the laboratory for determination of N, P, K and soil organic carbon. Particle size analysis was done using hydrometer method [11]. Soil nitrogen was determined by using Kjeldahl apparatus [12]. Soil phosphorus was assessed using spectrophotometer at 880 nm [13]. Soil potassium was determined by using flame photometer. Organic carbon content in the soil was determined through dichromate approach, using combustion at 160 °C for 30 minutes [14].

Nitrogen in plant samples was determined using Kjeldahl apparatus, according to Gunning and Hibbard’s method [12]. Total phosphorus in plant was determined by analyzing the samples through spectrometer at 400 nm [13] while potassium in plant samples was assessed by using flame photometer [13]. The protein and moisture contents of the tomato fruits were determined by standard protocols [15]. Potassium concentrations of tomato fruits were assessed by flame photometer, P by UV-visible spectrophotometer and N by Kjeldahl apparatus [16]. Protein was assessed by the Folin phenol reagent method by [17]. Vitamin C contents was determined according to 2,6-dichlorophenolindophenol method by [18].

The data collected were arranged and subjected to analysis using Statistix 8.1. Data were recorded as mean of three replications and the means of various treatments were compared using LSD (Least Significance Difference) test.

**Results and Discussion**

**Soil physico-chemical properties**

The soil samples were collected before crop transplanting from two depths i.e. 0-15 cm & 15-30 cm. Samples of same depth were mixed to form their composite samples and then were analyzed for soil physical & chemical parameters (Table 1). Results showed that the soil in experimental tunnel was silt loam and deficient in nitrogen, phosphorus and organic carbon. The organic matter (0.88%) in the upper depth (0-15 cm) was higher than the lower depth i.e. 15-30 cm (0.41%). The amount of organic C in upper depth (0-15 cm) was 0.52% which was found 0.24% in the lower depth (15-30 cm). Total nitrogen content in upper depth was found 0.05% as compared to 0.03% in the lower depth. Available phosphorus in the 0-15 cm depth was 7.5 µg P/g soil and decreased to 5.9 µg P/g soil in 15-30 cm depth. Maximum K (80 µg/g) was recorded in upper portion (0-15 cm) while minimum K (60 µg/g) was found in the lower portion (15-30 cm). Soil
was alkaline in reaction (pH 7.9-8.0), non-saline (EC 0.24-0.25 dS/m), moderately calcareous in nature 15.0 to 14.5% lime.

**Table 1. Soil physico-chemical properties before transplantation**

| Physico-chemical properties | Soil depth | Mean  |
|-----------------------------|------------|-------|
|                             | 0-15 cm | 15-30 cm |       |
| pH                          | 7.9     | 8.0     | 7.95  |
| Electrical conductivity (dS/m) | 0.24 | 0.25 | 0.25 |
| Organic carbon (%)          | 0.52    | 0.24    | 0.38  |
| Organic matter (%)          | 0.88    | 0.41    | 0.65  |
| Nitrogen (%)                | 0.05    | 0.03    | 0.04  |
| Phosphorus (µg/g)           | 7.5     | 5.9     | 6.7   |
| Potassium (µg/g)            | 80      | 60      | 70    |
| Lime content (%)            | 15.0    | 14.5    | 14.75 |

**Tomato fruit yield**

Mature tomato fruits in each treatment were collected at each harvest and weighed in kilograms. The total yield per treatment was calculated by adding the yield at all harvests for the same treatment. The effect of NPK on fresh yield of tomato applied at different days’ intervals is presented in (Table 2). The application of NPK at 7 days interval (T₃) produced maximum yield (294 kg/ Marla) followed by 175 kg/ Marla (14 days interval i.e. T₂) and 83 kg/Marla (21 days interval i.e. T₃). It was also observed that NPK applied at 7, 14 and 21 days intervals enhanced the yield significantly (P<0.05) as compared to T₀ i.e. no-NPK (50 kg/Marla). The highest dry straw yield (35 kg/ Marla) was recorded in T₁ followed by T₂ (25 kg/Marla), T₃ (18 kg/Marla) and lowest in control (10 kg/Marla). The results further indicated that there was a significant (P<0.05) difference among the treatments due to NPK application at different intervals. The results of our study were similar to [19], who investigated and reported that the response of various tomato cultivars varied to different rates of nitrogen and phosphorus application. In his study, NP fertilizers were applied at three different rates. He found that significantly higher fruit yield was obtained at NP application @ 110 kg N + 120 kg P₂O₅/ha. The results of our findings were also supported by [20] who reported that high NPK concentrations produce higher tomato fruit weight as compared to control. Moreover, increasing the phosphorus concentration gave maximum yield per tomato plant. Results were also in lines with [21], who reported that application of NPK in lower amounts may result in poor plant growth and less fruit production. From the present findings it was suggested that NPK fertilizer should be applied at 14 days interval to obtain economically higher yield.
Table 2. Effect of time intervals of NPK application on fruit and straw yield of off-season tomato

| Treatments   | Tomato yield | Dry straw yield |
|--------------|--------------|----------------|
|              | kg /Marla    | kg /Marla      |
| T₀ (Control) | 50 d         | 10 d           |
| T₁ (7 days interval) | 294 a       | 35 a           |
| T₂ (14 days interval)  | 175 b       | 25 b           |
| T₃ (21 days interval)  | 83 c        | 18 c           |

Values in each column indicated by similar letters are not significantly different at P≤0.05.

**Tomato fruit size/grading**

The data regarding the effect of NPK applied after each 7, 14 and 21 days intervals on fruit size (Grading) is presented in (Table 3). The maximum % age of A-Grade (100-140 g/fruit) was recorded in T₁ (62%) by application of NPK after each 7 days interval followed by T₂ (48%) and T₃ (36%) after each 14 and 21 days intervals, respectively. This increase in weight may be attributed to more nutrients availability and increased water and nutrients uptake by the plant that ultimately may result in higher photosynthesis rate and in return more food accumulation in fruits. The lowest (25%) A-Grade was found in control (T₀). It was examined the performance of eight tomato hybrids under plastic tunnel for early growth and various agronomic parameters [22]. He reported that the average single fruit weight of various tomato cultivars ranged between 103-202 g which is in line with our findings. Similar finding was obtained by [23, 24] who reported that under plastic tunnel the no. of fruits/ plant, single fruit weight and total weight of fruits/ plant were in the ranges of 20-57, 53-167 g and 2.0-4.78 kg, respectively. Likewise, [25] evaluated tuff and sand soil-less substrates in comparison with conventional growing in soil for the growth of tomato in a non-circulating open culture. Tomato plant grown in soil or tuff gave higher weight of fruit which ranged between 120-163 g whereas substrate has no effect on weight of fruit, which was quite similar to our findings. Moreover, foliar fertilization significantly increased the tomato growth, yield as well as quality [26]. The average fruit weight (81.60 g) was high with foliar spray along with NPK application.

Table 3. Effect of time intervals of NPK application on fruit grading of off-season tomato

| Treatments   | Tomato Grading (%) |
|--------------|---------------------|
|              | Grade-A (100-140 g/fruit) | Grade-B (50-100 g/fruit) | Grade-C (25-50 g/fruit) |
| T₀ (Control) | 25 c                | 33 b                   | 42 a                   |
| T₁ (7 days interval) | 62 a               | 28 c                   | 10 c                   |
| T₂ (14 days interval)  | 48 b               | 39 a                   | 13 b                   |
| T₃ (21 days interval)  | 36 b               | 42 a                   | 22 b                   |

Values in each column indicated by similar letters are not significantly different at P≤0.05.
Density, moisture, chlorophyll content and shelf life of tomato

The effect of NPK applied at different days’ intervals under high tunnel on tomato fruit density, moisture %, age, leaves chlorophyll content (SPAD value) and shelf life of tomato fruit is summarized in Table 4. The highest density (1.30 g/cm³) among the treatments was observed for T₁ followed by T₂ (1.20 g/cm³) and T₃ (0.99 g/cm³) whereas control (T₀) exhibited lowest density (0.80 g/cm³). These results are in range with the values reported by [27]. They found 0.95 to 1.96 g/cm³ density in various open pollinated and hybrid tomato cultivars. Similarly, maximum moisture (93.7%) content was recorded for T₂ having 14 days intervals of NPK application followed by T₁ (92.65%) having 7 days interval and control (90.80%), while T₃ showed minimum moisture content (90.40%). It was reported that 83.40 - 93.20% moisture content of tomato cultivars which justify our findings [27]. In case of chlorophyll content, the highest SPAD value (57.63) was noted for T₁ having each 7 days interval of NPK application followed by T₂ (56.43) and T₃ (53.54). However, T₀ has lowest chlorophyll content (46.28) among all the treatments. It was reported that 61.2 SPAD value of chlorophyll content after 84 days of nursery transplantation which are almost similar to our findings [28]. Potassium is one of the major factors influencing the tomato shelf life [29]. The results reveal that both treatments T₁ and T₂ have maximum shelf life (9 days) followed by T₃ (8 days) and T₀ (7 days). This may be attributed to the application of potassium, which was not applied to the control treatment (T₀). The findings were also supported by [30,31]; they reported that 375-400 kg K₂O/ha increased the post-harvest life of tomato fruits. The effect of enhanced potassium levels on the shelf life of tomato was also reported by [32]. Potassium occupies a pivotal position in improving many of the post-harvest quality traits in fruits of tomato as well as other vegetables [33]. Plants receiving higher K applications mature earlier and show minimum post-harvest losses like weight loss, thus help in retaining fruit texture and structure as was investigated by [31,34] who also reported that application of potassium @ 375-400 kg K₂O /ha increased the post-harvest life of tomato fruits.

Table 4. Effect of time intervals of NPK application on density, moisture, chlorophyll content and shelf life of off-season tomato

| Treatments       | Density (g/cm³) | Moisture (%) | Chlorophyll content (SPAD value) | Shelf life (Days) |
|------------------|----------------|--------------|----------------------------------|------------------|
| T₀ (Control)     | 0.80 b         | 90.80 a      | 46.28 b                          | 7.0 b            |
| T₁ (7 days interval) | 1.30 a         | 92.65 a      | 57.63 a                          | 9.0 a            |
| T₂ (14 days interval) | 1.20 a         | 93.70 a      | 56.43 a                          | 9.0 a            |
| T₃ (21 days interval) | 0.99 a         | 90.40 a      | 53.54 a                          | 8.0 ab           |

Values in each column indicated by similar letters are not significantly different at P≤0.05

NPK contents in tomato fruit

Effect of NPK fertilizer applied with different days’ intervals on the NPK content in fruit of tomato is described in (Table 5). Maximum N content in tomato fruit was recorded in T₁ (2.43%) followed by T₂ (2.33%), T₃ (2.16%) and T₀ (1.32%). Likewise, maximum P content was observed in T₁ (0.44%) followed by T₂ (0.39%), T₃ (0.30%) and T₀ (0.18%). In case of K, the
highest K content was recorded in T₁ (3.45%) followed by T₂ (3.36%), T₃ (2.80%) and T₀ (2.42%). It was reported that the application of NPK fertilizer tremendously increased N (2.3-3.62%), P (0.23-0.47%) and K (3.2-7.88%) contents of tomato fruit which justify our results [35].

Table 5. Effect of time intervals of NPK application on the mineral contents in off-season tomato fruit

| Treatments          | N (%) | P (%) | K (%) |
|---------------------|-------|-------|-------|
| T₀ (Control)        | 1.32 c| 0.18 c| 2.42 c|
| T₁ (7 days interval)| 2.43 a| 0.44 a| 3.45 a|
| T₂ (14 days interval)| 2.33 ab| 0.39 a| 3.36 a|
| T₃ (21 days interval)| 2.16 b| 0.30 b| 2.80 b|

Values in each column indicated by similar letters are not significantly different at P<0.05.

NPK contents in tomato straw
Effect of NPK fertilizer applied with different days’ intervals on the NPK contents in straw of tomatoes is described in (Table 6). Maximum N was recorded in T₁ (1.25%) followed by T₂ (1.19%), T₃ (1.05%) and T₀ (0.80%). Similarly, the highest P content was found in T₁ (0.20%) followed by T₂ (0.18%), T₃ (0.17%) and T₀ (0.10%). In case of K, the highest K content was observed in T₁ (1.45%) as compared to T₂ (1.35%), T₃ (1.23%) and T₀ (1.08%). The results of the finding revealed overall uptake of NPK by straw was higher when NPK fertilizer was applied at 7 days intervals as compared to other treatments. It was reported that nitrogen, phosphorus and potassium are required for better plant growth and fruit development, so their lower amounts decreased the yield of tomato plant [21].

Table 6. Effect of time intervals of NPK application on the mineral contents in off-season tomato straw

| Treatments          | N (%) | P (%) | K (%) |
|---------------------|-------|-------|-------|
| T₀ (Control)        | 0.80 c| 0.10 b| 1.08 c|
| T₁ (7 days interval)| 1.25 a| 0.20 a| 1.45 a|
| T₂ (14 days interval)| 1.19 ab| 0.18 a| 1.35 ab|
| T₃ (21 days interval)| 1.05 b| 0.17 a| 1.23 b|

Values in each column indicated by similar letters are not significantly different at P<0.05.

Total NPK uptake of tomato
Plant nutrition is one of the vital factors affecting the proper growth & development of the plants. Methods as well as time of fertilizer application are key components for supplying the nutrients to the plants adequately as the soil applied fertilizers may be lost or fixed resulting in lower efficacy of these nutrients. The data in Table 7 shows the effect of NPK applied after each 7, 14 and 21 days intervals on total NPK uptake of tomato. The maximum total nitrogen uptake (9.62 kg/10 Marla tunnel) was recorded in T₁ fertilized at 7 days interval followed by T₂ (5.51 kg/10
Marla tunnel) and the minimum was recorded in T₀ (0.14 kg/ 10 Marla tunnel). Likewise, the highest total phosphorus uptake (1.64 kg/ 10 Marla tunnel) was recorded in T₁ followed by T₂ (0.92 kg/ 10 Marla tunnel), T₃ (0.54 kg/ 10 Marla tunnel) and T₀ (0.02 kg/ 10 Marla tunnel). In case of K, the highest K uptake was recorded in T₁ (12.44 kg/ 10 Marla tunnel) as compared to T₂ (7.05 kg/ 10 Marla tunnel), T₃ (4.41 kg/ 10 Marla tunnel) and T₀ (0.22 kg/ 10 Marla tunnel). It was investigated that NPK nutrients are required for better plant growth and fruit development, so their lower concentrations decreased NPK uptake and ultimately the plant yield [21].

Table 7. Effect of time intervals of NPK application on total NPK uptake of off-season tomato

| Treatments         | N     | P     | K     |
|--------------------|-------|-------|-------|
| T₀ (Control)       | 0.14 d| 0.02 d| 0.22 d|
| T₁ (7 days interval)| 9.62 a| 1.64 a| 12.44 a|
| T₂ (14 days interval)| 5.51 b| 0.92 b| 7.05 b|
| T₃ (21 days interval)| 3.60 c| 0.54 c| 4.41 c|

Values in each column indicated by similar letters are not significantly different at P≤0.05

**Nutritional quality of tomato fruit**

TSS (total soluble solids), pH, total acidity, protein & vitamin C content are key quality parameters contributing towards the stability of tomatoes while processing and storage. The effect of NPK fertilizer applied with different days’ intervals on the nutritional quality of tomatoes is described in Table 8. As depicted from the table, the total soluble solid (TSS) content varied from 5.4 °Brix in T₁ receiving fertilizer application at 7 days intervals of time to 4.6 °Brix in T₀ receiving no fertilizer at all, [36] noted that maximum TSS contents was achieved in cultivar Sahel (6.33 °Brix). This may be justified on account of higher potassium application as was reported by [34] that higher application of K resulted in significantly higher concentration of total soluble solids. pH of tomatoes juice (Table 8) was highest in treatment receiving fertilizer application at 14 days intervals (4.6) while the least (3.9) was found in treatment receiving fertilizer application at 7 days intervals. Non-significance difference was found in all treatments regarding total acidity content, however, the highest value was recorded for T₁ (0.44%) and the lowest value for T₀ (0.34%).

Highest protein content (15.40%) was found in tomato fruits receiving fertilizer application at 7 days intervals whereas the lowest one (8.75%) was recorded in the tomato fruits that were applied no fertilizer at all. Vitamin C content of tomato juice ranged from 17.06 to 29.64 mg100g⁻¹, with the highest content in treatment of 21 days intervals of fertilizer application and the least content in that of no fertilizer application. Generally, tomatoes are not a good source of protein, but hybrid cultivars containing protein up to12% have been reported by [37]. The higher content of protein in the tomato fruits, in the present study, was due to the consistent supply of nitrogen which is a key component for protein biosynthesis. Our results regarding higher protein content may be fairly supported by the ‘C/N balance theory’ which explains that with consistent availability of N, plants will go on making high N compounds like protein.
Table 8. Effect of time intervals of NPK application on the nutritional quality of off-season tomato fruit

| Treatments       | TSS (°Brix) | pH | Total Acidity (%) | Protein (%) | Vitamin C (mg /100 g) |
|------------------|-------------|----|-------------------|-------------|----------------------|
| T₀ (Control)     | 4.6 b       | 4.3 a | 0.34 a            | 8.75 c      | 17.06 c              |
| T₁ (7 days interval) | 5.4 a     | 3.9 b | 0.44 a            | 15.40 a     | 18.30 c              |
| T₂ (14 days interval) | 5.1 a      | 4.6 a | 0.43 a            | 14.32 a     | 24.02 b              |

Values in each column indicated by similar letters are not significantly different at P<0.05.

Conclusion
Findings of this research indicate that application of NPK @ 10-10-15 kg ha⁻¹ at 7 days intervals through drip irrigation to “Sahel hybrid” tomatoes in high tunnels could be recommended to the growers of Peshawar Valley or of similar agro-climatic regions for higher tomato productivity and quality.

Authors’ contributions
Conceived and designed the experiments: P Khan & M Imtiaz, Performed the experiments: P Khan, M Imtiaz & SA Ali, Analyzed the data: P Khan & SA Ali, Contributed materials/ analysis/ tools: P Khan, M Imtiaz & SA Ali, Wrote the paper: P Khan, M Imtiaz & SA Ali.

Acknowledgement
We acknowledge The University of Agriculture, Peshawar, Endowment Fund for providing financial support for this project.
