The transcytosis of antigens across the follicle-associated epithelium (FAE) of Peyer’s patches by microfold cells (M cells) is important for the induction of efficient immune responses to mucosal antigens. The mucosal immune response is compromised by ageing, but effects on M cells were unknown. We show that M-cell density in the FAE of aged mice was dramatically reduced. As a consequence, aged Peyer’s patches were significantly deficient in their ability to transcytose particulate luminal antigen across the FAE. Ageing specifically impaired the expression of Spi-B and the downstream functional maturation of M cells. Ageing also dramatically impaired C-C motif chemokine ligand 20 expression by the FAE. As a consequence, fewer B cells were attracted towards the FAE, potentially reducing their ability to promote M-cell maturation. Our study demonstrates that ageing dramatically impedes the functional maturation of M cells, revealing an important ageing-related defect in the mucosal immune system’s ability to sample luminal antigens.

INTRODUCTION

The gastrointestinal tract is continuously exposed to large amounts of microorganisms. As well as mounting an effective immune response against food-borne pathogens, the mucosal immune system must also recognize the harmless antigens associated with food and commensal microorganisms and generate immunological tolerance against them. The luminal surface of the intestine limits the access of pathogenic microorganisms to the underlying host tissues and is protected by a single layer of epithelial cells bound by tight junctions. In order to mount an immune response, gut luminal antigens must first be transported across the intestinal epithelium. Located within the specialized follicle-associated epithelia (FAE) overlying the gut-associated lymphoid tissue such as Peyer’s patches and isolated lymphoid follicles are microfold cells (M cells). This unique subset of epithelial cells is specialized for the transcytosis of luminal macromolecules, particulate antigens, and pathogenic or commensal microorganisms.1–3 Following their uptake and transcytosis by M cells, antigens exit into the intraepithelial pocket beneath the basolateral membrane where they are subsequently processed by macrophages and classical dendritic cells. In the absence of M cells, antigen-specific T-cell responses in the Peyer’s patches of mice orally infected with Salmonella typhimurium are significantly impaired.4

The mucosal immune response in the intestine is significantly compromised by ageing.5–8 The age-related decline in immune competence is associated with diminished antigen-specific immunoglobulin A antibody titers in the intestinal lumen6,9 and a decreased ability to generate tolerance to harmless antigens.7 The age-related increases in the incidence and severity of gastrointestinal infections, cancer, inflammatory diseases, coupled with decreases in the efficacy of vaccinations, illustrate the importance of studies aimed at understanding the factors involved in this immunosenescence. Many studies have addressed the age-related changes to systemic immune responses, particularly the ageing effects on T-cell responses, but little is known of the mechanisms underlying the decline in intestinal immunity.

The transcytosis of antigens by M cells is an important initial step in the induction of efficient immune responses to certain antigens, such as microorganisms. Furthermore, the targeted
delivery of vaccine antigens to M cells has been shown to be an effective means of inducing antigen-specific immune responses. However, despite the important role of M cells in mucosal immunity, nothing was known about the effects of ageing on their development and function. The identification of the cellular and molecular factors affected in the senescent mucosal immune system is crucial for the development of mucosal vaccines and effective strategies to improve intestinal immunity in the aged. Therefore, in the current study, a mouse model was used to determine the effects of ageing on M-cell status. Our data show, for the first time, that there is a dramatic decline in the functional maturation of M cells in the Peyer’s patches of aged mice.

RESULTS

M-cell density is significantly reduced in the FAE of aged mice
First we used whole-mount immunohistochemistry (IHC) to compare the number of M cells in the FAE of Peyer’s patches from young adult (6–8 weeks old) and aged C57BL/6 mice (>18 months old). Glycoprotein 2 (GP2) is a specific surface marker for mature M cells. As anticipated, large numbers of GP2 M cells with characteristic basolateral pockets were detected in the FAE of Peyer’s patches of young mice. However, the number of GP2 M cells in the FAE of aged mice was dramatically and significantly reduced (Figure 1a,b; P < 0.0001, Mann–Whitney U test). The number of M cells in the FAE of aged mice was <25% that observed in young mice. Real-time quantitative PCR analysis showed that there was also a significant reduction in Gp2 mRNA expression in Peyer’s patches from aged mice (Figure 1c; P < 0.022, Student’s t-test).

Although the number of Peyer’s patches was not affected by host’s age, morphometric analysis suggested that the size of the FAE in those from aged mice was typically 30% smaller (Figure 1d; P < 0.0039, Student’s t-test). However, the reduced number of M cells in aged Peyer’s patches was not simply due to a reduction in the overall size of the FAE, as the density of M cells in aged mice was also significantly reduced (Figure 1e; P < 0.001, Mann–Whitney U test). In contrast to the effects of ageing on M cells, the density of goblet cells recognized by their morphology, lack of GP2 expression, and binding of the lectin Ulex europaeus agglutinin-1 (UEA-1; GP2 UEA-1 cells) in the FAE of aged mice was similar to that observed in the FAE of young mice (Figure 1f; P = 0.704, Student’s t-test). These data demonstrate that M-cell density is dramatically reduced in the FAE of aged mice.

The uptake of particulate antigen into the Peyer’s patches of aged mice is significantly impaired
We next determined whether the reduced density of GP2 M cells in the FAE of aged mice correlated with effects on the uptake of particulate antigen from the gut lumen. The assessment of the uptake of fluorescent latex beads injected into ligated loops of the small intestine is a useful quantitative method to compare the functional ability of M cells in vivo to take up particulate antigen from the gut lumen and transcytose them to underlying mononuclear phagocytes in their intraepithelial pockets. Peyer’s patches in groups of young and aged mice were surgically ligated and injected with fluorescent 200-nm latex beads. The Peyer’s patches were then removed 1 h after injection, and the number of beads taken up into each tissue was quantified microscopically. In Peyer’s patches from young mice, many fluorescent beads had been transcytosed across the FAE (Figure 2). However, in tissues from aged mice, substantially fewer, if any, beads had passed through the FAE (Figure 2; P < 0.0061, Student’s t-test).

Receptor activator of NF-κB ligand (RANKL) and RANK expression are not adversely affected in the Peyer’s patches of aged mice
The production of RANKL by the subepithelial stromal cells beneath the FAE is a critical factor that stimulates the differentiation of receptor activator of NF-κB (RANK)-expressing enterocytes into M cells. As M cells are depleted in vivo by RANKL neutralization, and are absent in RANKL-deficient mice, we determined whether the reduced M-cell density in aged mice was due to impaired RANKL stimulation. No difference was observed in the expression or distribution of RANKL in Peyer’s patches from young and aged mice (Figure 3a,b). In tissues from each group, high levels of RANKL expression were specifically restricted to stromal cells in the subepithelial dome. Similarly, no significant difference in the expression of Tnfsf11 (which encodes RANKL), Tnfrsf11a (which encodes the RANK receptor, RANK), or Tnfrsf11b (which encodes the RANK decoy receptor osteoprotegerin, OPG) mRNA levels were detected in the Peyer’s patches from young or aged mice (Figure 3c–e, respectively). Thus, the effects of ageing on M-cell status were not due to reduced expression of RANKL or RANK or impaired RANKL–RANK stimulation due to elevated expression of OPG.

Cells within the FAE have a limited lifespan of approximately 5 days and are constantly replaced by those that differentiate and migrate from stem cells within the dome-associated crypts adjacent to the gut-associated lymphoid tissue. We therefore determined whether ageing affected cell proliferation. IHC analysis showed that although there was a dramatic reduction in the number of proliferating cells (Ki-67 cells) in the Peyer’s patch follicles of aged mice, no difference was observed in the dome-associated crypts (Supplementary Figure S1 online). Similarly, ageing was not associated with increased levels of apoptosis in the FAE. Apoptotic cells were rare in the FAE of young and aged mice. As anticipated, tingible body macrophages in the B-cell follicles contained large numbers of TUNEL (terminal deoxynucleotidyl transferase mediated dUTP nick-end labeling assay positive; apoptotic) cells (Supplementary Figure S2 online).17

Ageing impairs the maturation of M cells
Annexin A5 (ANXA5) is also a specific marker for M cells in the FAE. The systemic treatment of mice with RANKL induces the differentiation of RANK-expressing villous enterocytes into M cells. Consistent with this role, analysis of microarray data from the intestines of RANKL-treated mice shows that by 6 h,
a significant increase in \textit{Anxa5} mRNA expression was observed in the villous epithelium, reaching peak levels by 48 h (Figure 4a). However, \textit{Gp2} expression was not induced until 48 h after exposure (Figure 4a). These data show that \textit{GP2} is restricted to more mature M cells, whereas \textit{ANXA5} is also expressed by immature/differentiating M cells.\textsuperscript{,3,4} Ageing did not significantly influence the expression level of \textit{Anxa5} mRNA (Figure 4b). As anticipated, many \textit{GP2}\textsuperscript{+} \textit{ANXA5}\textsuperscript{+} M cells were detected by IHC in the FAE of Peyer’s patches of young mice (Figure 4c). However, consistent with the mRNA expression data (\textit{Gp2}, Figure 1c; \textit{Anxa5}, Figure 4b) our double IHC analysis showed that although the expression of \textit{GP2} was significantly reduced in the aged FAE (Figure 4c,d; \(P<0.0001\), Mann–Whitney \(U\) test), the expression of \textit{ANXA5} was
unaffected (Figure 4c,e; \(P = 0.340\), Student’s \(t\)-test). These data show that ageing specifically affects the differentiation of immature ANXA5\(^+\) cells into functionally mature GP2\(^+\)M cells.

Expression of the Ets transcription factor Spi-B is reduced in the FAE of aged mice

The maturation of M cells has been shown to be mediated by their intrinsic expression of the Ets transcription factor Spi-B.\(^4\) Cells in the FAE of Peyer’s patches from Spi-B-deficient mice express equivalent levels of the immature M-cell marker ANXA5 compred with wild-type mice but lack expression of mature M-cell markers such as GP2 and are defective in their ability to transcytose antigens.\(^4\) As these characteristics were similar to those observed in the aged FAE, we examined whether the reduced maturation of M cells in aged mice was due to effects on Spi-B expression. Our analysis showed that although large numbers of Spi-B\(^+\) cells were detected throughout the FAE of young mice, they were significantly reduced in the FAE of aged mice (Figure 5; \(P < 0.0001\), Student’s \(t\)-test).

Ageing dramatically impairs the expression of C-C motif chemokine ligand 20 (CCL20) by the FAE

The FAE-specific expression of the chemokine CCL20 also has an important role in M-cell differentiation. CCL20 mediates the chemoattraction of CCR6-expressing lymphocytes and leukocytes towards the FAE.\(^19\) In the absence of CCL20–CCR6 stimulation M-cell maturation is impaired.\(^20\) In young mice, as anticipated, dense CCL20-specific immunolabeling was detected exclusively in association with the FAE. However, CCL20 expression was significantly reduced in the FAE of aged mice.

Figure 2  The uptake of particulate antigen into the Peyer’s patches of aged mice is significantly impaired. (a) In Peyer’s patches from young mice, many fluorescent beads (arrows, green) had been transcytosed across the follicle-associated epithelium (FAE). Substantially fewer, if any, beads appeared to have passed through the FAE of aged mice. Sections were counterstained to detect f-actin (blue). Broken line indicates the lumenal surface of the FAE. (b) The number of beads transcytosed across the FAE of aged mice was significantly less than that observed in Peyer’s patches from young mice (\(P < 0.0061\), Student’s \(t\)-test). Data were collected from 10 sections from each Peyer’s patch. Data are derived from 3–5 Peyer’s patches from four mice from each group. SED, subepithelial dome.

Figure 3  Ageing does not influence the expression of receptor activator of NF-κB ligand (RANKL), RANK, and osteoprotegerin (OPG) in Peyer’s patches. (a) Immunohistochemical (IHC) analysis suggested that there was no observable difference in the expression or distribution of RANKL on subepithelial dome (SED) of the stromal cells in Peyer’s patches from young and aged mice. Broken line indicates the lumenal surface of the follicle-associated epithelium (FAE). (b) Morphometric analysis confirmed that the magnitude of RANKL-specific immunostaining observed in the SED of Peyer’s patches from young and aged mice was similar. Quantitative real-time reverse transcriptase–PCR analysis suggested that there was no significant difference in the expression of (c) Tnfsf11 (RANKL), (d) Tnfrsf11a (RANK), or (e) Tnfrsf11b (OPG) mRNA levels between Peyer’s patches from young or aged mice. Gene expression data are normalized so that the mean level in young mice was 1.0. Data are derived from 3–5 Peyer’s patches from at least four mice/group.
mice (Figure 6a,b; \( P < 0.0001 \), Student’s \( t \)-test). Whole-mount \textit{in situ} hybridization analysis also demonstrated a substantial reduction in the expression of \textit{Ccl20} mRNA in the FAE of aged mice (Figure 6c). CCR6-deficient mice display a comparable reduction in the density of mature GP2\(^+\) M cells in the FAE\(^20\) to that observed in aged mice in the current study. Whether CCR6 deficiency affects the initial induction of M-cell development in the FAE and their expression of immature M-cell markers such as ANXA5 is not known. Our analysis revealed that the expression of ANXA5 in the FAE of CCR6\(^{-/-}\) mice was unaffected when compared with wild-type mice (Supplementary Figure S3 online). These data show that, as observed in aged mice, CCL20–CCR6-signaling blockade in CCR6\(^{-/-}\) mice does not affect the initial induction of M-cell differentiation (expression of ANXA5; Supplementary Figure S3 online) but specifically impedes their maturation (expression of GP2 and ability to transcyose Ag).\(^20\) Together, these data suggest that the effects of aging on the functional maturation of M cells were also due to impaired CCL20 expression by the FAE.

Pathogen-associated molecular patterns (PAMPs) derived from intestinal bacteria, such as lipopolysaccharide and flagellins, can modulate cytokine and chemokine expression by intestinal epithelial cells via stimulation through Toll-like receptors (TLRs). As flagellin can induce CCL20 expression in the intestinal epithelium via stimulation through TLR5,\(^21,22\) we determined whether the intestinal concentrations of proinflammatory bacterial TLR ligands were altered in aged mice. Sterile-filtered fecal (SFE) extracts were prepared as representative samples of the soluble PAMP in the gut lumen of mice from each age group. PAMP specific for TLR4 (lipopolysaccharide equivalents) and TLR5 (flagellin equivalents) in SFE were quantified using HEK-293 cells transfected with the
Figure 5  Effects of ageing on Spi-B expression in the follicle-associated epithelium (FAE) of Peyer’s patches. (a) Immunohistochemical analysis suggested that Spi-B (green) was reduced in the FAE of aged mice. Boxed area in upper panels is shown at higher magnification in lower panels. Broken line indicates the lumenal surface of the FAE. (b) Morphometric analysis showed that the magnitude of the Spi-B-specific immunostaining and number of Spi-B⁺ cells were significantly reduced in the FAE of aged mice (P<0.0001, Student’s t-test). Data are derived from 4–6 Peyer’s patches from eight mice from each group. SED, subepithelial dome.

Figure 6  Effects of ageing on C-C motif chemokine ligand 20 (CCL20) expression in the follicle-associated epithelium (FAE) of Peyer’s patches. (a) Immunohistochemical analysis suggested that CCL20 (red) was reduced in the FAE of aged mice. Broken line indicates the lumenal surface of the FAE. (b) Morphometric analysis showed that the magnitude of CCL20-specific immunostaining observed in aged mice was significantly reduced (P<0.0001, Student’s t-test). Data are representative of 3–5 Peyer’s patches from eight mice from each group. (c) Whole-mount in situ hybridization analysis demonstrated a dramatic reduction in Ccl20 mRNA expression in the Peyer’s patches of aged mice when compared with young mice. Data are derived from 21 Peyer’s patches from each group. SED, subepithelial dome.
respective TLRs and calibrated with defined standard PAMP. Our analysis showed that ageing did not significantly alter the intestinal concentrations of proinflammatory ligands of TLR4 and TLR5 (Supplementary Figures S4a,b online). Similarly, no significant difference was observed in the ability of the PAMP within SFE from young and aged mice to induce CCL20 mRNA expression in in vitro-cultivated Caco-2 intestinal epithelial cells (Supplementary Figure S4c online). These data suggest that the effects of ageing on CCL20 expression in the FAE were not due to alterations to the PAMP profile of the gut microbiota.

**The density of CD11c^+ B cells in the FAE of aged mice is significantly reduced**

A unique subset of CCR6-expressing “M-cell-inducing” CD11c^+ B cells has been shown to migrate towards FAE-derived CCL20 and have an important role in stimulating M-cell differentiation. We therefore compared the distribution of T cells, B cells, and CD11c^+ cells in the FAE of young and aged mice. Coincident with the effects of ageing on CCL20 expression, the densities of T cells (CD3^+ cells; Figure 7a,b; P<0.014, Student’s t-test) and B cells (CD45R^+ cells; Figure 7c,d; P<0.025, Student’s t-test) were significantly reduced in the FAE of aged mice. Although no significant difference in the total density of CD11c^+ cells was observed (Figure 7e,f; P = 0.656, Student’s t-test), our data implied that the density of CD11c^+ B cells was significantly reduced in the FAE of aged mice (CD11c^+ CD45R^+ cells; Figure 7g,h; P<0.020, Student’s t-test). The density of the CD11c^+ B cells in the aged FAE appeared to be more profoundly decreased than that of the conventional B cells (38% and 65% density observed in young mice, respectively), consistent with the higher expression level of CCR6 on CD11c^+ B cells. The CD11c^+ CD45R^+ cells were not plasmacytoid dendritic cells as they lacked expression of the typical plasmacytoid dendritic cell markers, PDCA-1 and Gr-1 (Figure 7i,j). Together, these data show that, as a consequence of the impaired CCL20 expression in the Peyer’s patches of aged mice, fewer B cells are attracted towards the FAE (including those which appeared to express CD11c), potentially impeding their ability to stimulate M-cell differentiation.

**DISCUSSION**

Here we show that the density of M cells in FAE of aged mice is dramatically reduced, significantly impeding the transcytosis of particulate antigen across the gut epithelium. Ageing specifically impaired the expression of Spi-B and downstream functional maturation of M cells. Expression of the chemokine CCL20 was also reduced in the FAE of aged mice, impeding the attraction of B cells towards the FAE. The M-cell intrinsic expression of Spi-B^4 and CCL20-mediated attraction of CCR6-expressing CD11c^+ B cells towards the FAE each have important roles in the induction of M-cell differentiation. Taken together, these data suggest that the effects of ageing on Spi-B and CCL20 expression in the FAE dramatically impede the functional maturation of M cells in Peyer’s patches. Data in the current study reveal an important ageing-related deficiency in the mucosal immune system’s ability to sample luminal antigens.

The expression of high levels of RANKL by stromal cells directly beneath the FAE has a critical role in controlling the differentiation of M cells from intestinal epithelial precursor cells. In the absence of RANKL, M-cell differentiation is blocked. As RANKL is a critical factor that provides the initial stimulus to trigger the differentiation of M cells from RANK-expressing enterocytes, we compared the expression levels of RANKL and RANK in the young and aged Peyer’s patches. However, the expression of RANKL and RANK was not adversely affected in aged mice. This indicates that factors downstream of RANKL–RANK signaling are responsible for the impaired M-cell development in aged mice. OPG is a secreted decoy receptor of RANKL and its enhanced expression can suppress RANKL stimulation. However, our data show that the relative expression levels of OPG and RANKL were not influenced in the Peyer’s patches of aged mice.

ANXA5 and GP2 are both specifically expressed by M cells. Analysis of the effects of RANKL stimulation on gene expression in the villous epithelium showed that although Anxa5 was rapidly induced within hours of exposure, Gp2 was induced at a much later time after treatment. These data support the view that GP2 is restricted to terminally differentiated M cells and also indicate that ANXA5 is expressed by immature (and mature) M cells. These data also suggest that the expression of Anxa5 and Gp2 are regulated by different transcriptional mechanisms: Anxa5 expression in the intestinal epithelium is rapidly induced by RANKL stimulation, whereas Gp2 is not directly induced by RANKL stimulation. The expression of ANXA5 in the FAE of aged mice was unaffected, indicating that the RANKL–RANK signaling events leading to ANXA5 expression were not influenced by ageing. However, GP2 expression was significantly impaired. These data show that ageing does not affect the induction of M-cell differentiation but specifically impedes their maturation. These data also show that RANKL stimulation is critical for the induction of M-cell differentiation, whereas RANKL stimulation alone is insufficient to maintain their functional maturation.

M-cell intrinsic expression of the Ets transcription factor Spi-B is essential for their functional maturation and expression of mature M-cell markers, such as GP2. However, the expression of early M-cell markers, including ANXA5, is independent of Spi-B. In the current study, similar effects on the functional maturation of M cells were observed in the FAE of aged mice to those observed in Spi-B-deficient mice. Expression of ANXA5 was comparable in the young and aged mice, but the expression of Spi-B and the mature M-cell marker GP2 was significantly reduced. Furthermore, as observed in the Peyer’s patches of Spi-B-deficient mice, the residual ANXA5^+ cells in the FAE of aged mice were defective in their ability to transcytose particulate antigen from the gut lumen. These data suggest that ageing adversely affects the induction and/or maintenance of Spi-B expression, impairing the functional maturation of M cells.

Lymphoepithelial interactions also promote M-cell differentiation. A unique subset of M-cell inducing CCR6-expressing...
CD11c⁺ B cells has been shown to migrate towards FAE-derived CCL20 and have an important role in stimulating M-cell differentiation. Mice deficient in CCR6, the sole receptor for CCL20, have a reduced frequency of mature GP2⁺ M cells in the FAE. In the current study, the reduced expression of Spi-B and impaired functional maturation of M cells coincided with a similar reduction in CCL20 expression by the FAE. Indeed, the CCR6-deficient mice show a comparable reduction in the density of mature M cells in the FAE to that observed in aged mice (current study). We also show that, as observed in aged mice, CCR6 deficiency did not affect the expression of immature M-cell markers such as ANXA5 but specifically impeded their maturation. Together, these data suggest that the effects of aging on the functional maturation of M cells were also a consequence of the reduced CCL20 expression, impeding the migration of B cells (including those which appeared to express CD11c) towards the FAE.

The underlying mechanism responsible for the reduced expression of Spi-B and CCL20 in the Peyer’s patches of aged mice, which ultimately impede the functional maturation of M cells in the FAE, is uncertain. Our data show that these effects were not due to reduced cell proliferation in the dome-associated crypts, increased apoptosis in the FAE, impaired RANKL–RANK stimulation due to elevated expression of the RANKL decoy receptor OPG, or alterations to the concentrations of proinflammatory ligands of TLR4 and TLR5 in the intestine.

Data in the current study provide an important advance in our understanding of the effects of ageing on the mucosal immune system. The effective uptake of antigens by M cells is...
an important initial step in the induction of an efficient immune response to some microorganisms or after oral vaccination. Our data show that due to the reduced density of mature M cells in the FAE, the uptake of particulate antigen from the gut lumen is significantly compromised in aged individuals. Antigen-specific mucosal immune responses are markedly diminished in Spi-B-deficient and CCR6-deficient mice, which display a dramatic reduction in the density of mature M cells in the FAE. Furthermore, CCR6-deficient mice display a similar reduction in M-cell density to that observed in aged mice in the current study. Similarly, in the absence of GP2 expression by M cells, antigen-specific immunoglobulin A responses against type-1 piliated bacteria are also attenuated. This suggests that the effects of aging on the functional maturation of M cells and their expression of GP2 may significantly contribute to the impaired antigen-specific mucosal immune responses observed in aged mice. The targeted delivery of vaccine antigens to M cells is an effective means of inducing antigen-specific mucosal immune responses to certain antigens. Data in the current study suggest that such strategies may be less effective when used to immunize the elderly. However, the effects of aging on M-cell status may also reduce susceptibility to some pathogens that specifically exploit M cells to infect the host. For example, M cells are important sites of prion uptake from the gut lumen, and disease susceptibility after oral exposure is blocked in their absence. Susceptibility to oral prion infection is dramatically reduced in aged mice. Thus, it is plausible that the effects of aging on M-cell maturation may reduce susceptibility to orally acquired prion infection by impeding their initial uptake into Peyer’s patches. The enteroinvasive bacterium S. typhimurium is also considered to exploit M cells to establish infection after oral exposure, and its translocation into Peyer’s patches is impeded in the absence of M cells or their expression of GP2. The significantly reduced early uptake of S. typhimurium into the Peyer’s patches of aged mice may likewise be a consequence of the effects of aging on M-cell status. A thorough analysis of the molecular mechanisms that underpin the dramatic decline in the functional maturation of M cells in aged mice will aid our understanding of the factors that influence susceptibility to mucosally acquired pathogens and identify novel approaches to stimulate M-cell differentiation and improve mucosal immunity in the elderly.

IHC analyses. For whole-mount staining, Peyer’s patches were dissected and fixed with BD Cytofix/Cytoperm (BD Biosciences, Oxford, UK). Tissues were subsequently immunostained with rat anti-mouse GP2 mAb (MBL International, Woburn, MA). Following addition of primary Ab, tissues were stained with Alexa Fluor 488-conjugated anti-rat IgG Ab (Invitrogen, Paisley, UK); rhodamine-conjugated Ulex europaeus agglutinin I (UEA-1; Vector Laboratories, Burlingame, CA), and Alexa Fluor 647-conjugated phalloidin (Invitrogen).

For analysis of tissue sections, Peyer’s patches were removed and snap-frozen at the temperature of liquid nitrogen. Serial frozen sections (5 μm in thickness) were immunostained with the following antibodies: rat anti-mouse GP2 mAb to detect M cells; rat anti-mouse CD254 to detect RANKL (clone IK22/5; ebioscience, Hatfield, UK); rabbit anti-Ki67 polyclonal Ab (Abcam, Cambridge, UK); rabbit anti-annexin V polyclonal Ab (Abcam); biotinylated hamster anti-mouse CD3e mAb (clone 500-A2; Caltag-Medsystems, Buckingham, UK); Alexa Fluor 488-conjugated rat anti-mouse CD45R (B220) mAb (clone RA3-6B2; Invitrogen); rat anti-mouse PDCA-1 mAb (clone JF05-1C2.4.1; Miltenyi Biotech, Surrey, UK); rat anti-mouse Ly-6G (Gr-1) mAb (clone RB6-8C5; ebioscience); biotinylated hamster anti-mouse CD11c mAb (clone HL3; BD Biosciences). For the detection of CCL20, tissues were first fixed in 4% paraformaldehyde before sectioning and immunostaining with goat anti-mouse CCL20 polyclonal Ab (R&D Systems, Abingdon, UK). For the detection of Spi-B in paraformaldehyde-fixed sections, antigen retrieval was performed with citrate buffer (pH 7.0, 121 °C, 5 min.) before immunostaining with sheep anti-mouse Spi-B polyclonal Ab (Abcam) and Alexa Fluor 555 (red) dye were used (Invitrogen). Sections were mounted in fluorescent mounting medium (Dako, Ely, UK) and examined using a Zeiss LSM5 confocal microscope (Zeiss, Welwyn Garden City, UK).

In vivo assessment of M-cell-mediated transcytosis. The in vivo uptake of 200-nm diameter fluoresbrite YG carboxylate microspheres (Polysciences, Eppelheim, Germany) from the gut lumen was assessed using a gut-loop model as described. Briefly, to prepare isolated small intestinal loops, mice were anesthetized and segments of small intestine (5 cm in length) were cut and placed back in the peritoneal cavity. Approximately 1 h later, the injected gut loops were excised, washed in 0.5% Tween 20-phosphate-buffered saline (1 × 1011 beads per ml). The isolated gut loops were then placed back in the peritoneal cavity. Approximately 1 h later, the injected gut loops were excised, washed in 0.5% Tween 20-phosphate-buffered saline, fixed in 4% paraformaldehyde in phosphate-buffered saline (pH 7.2), 24 h, and stored in 70% ethanol. Immunostaining with sheep anti-mouse Spi-B polyclonal Ab was performed as described. Sections were mounted in fluorescent mounting medium (Dako, Ely, UK) and examined using a Zeiss LSM5 confocal microscope (Zeiss, Welwyn Garden City, UK).

METHODS

Mice. C57BL/6 mice were aged to at least 18 months old before analysis. Six-to-eight-week old C57BL/6 mice were used as young adults. All mice from each group received identical diets and were housed and maintained under identical specific pathogen-free conditions. Throughout this study, tissues from at least three independent cohorts of young and aged mice were analyzed. CCR6-EGFP knock-in mice were backcrossed onto C57BL/6 mice for at least eight generations before analysis. All studies using experimental mice and regulatory licenses were approved by the following authorities: United Kingdom, the University of Edinburgh’s Ethical Review Committee and performed under the authority of a UK Home Office Project License within the regulations of the UK Home Office “Animals (scientific procedures) Act 1986”; Japan, by the Animal Research Committee of the RIKEN Yokohama Research Institute.
positively immunostained pixels in images of specific Peyer’s patch regions were collected.

Quantitative real-time PCR analysis of mRNA expression. Total RNA was isolated from Peyer’s patches using RNA-Bee (AMS Biotechnology, Oxfordshire, UK) followed by treatment with DNase I (Ambion, Warrington, UK). First-strand cDNA synthesis was performed using 1 μg of total RNA and the First Strand cDNA Synthesis kit (GE Healthcare, Bucks, UK) as described by the manufacturer. PCR amplification reactions were performed using the Platinum SYBR Green qPCR SuperMix-UDG kit (Invitrogen) and the Stratagene Mx3000P real-time qPCR system (Stratagene, CA, USA). All quantitative PCR primers used were designed using Primer3 software (http://primer3plus.com),34 and their details are provided in Supplementary Table S1 online. The cycle threshold values were determined using MxPro software (Stratagene) and normalized to the value of Actb.

Whole-mount RNA in situ hybridization. A 721-bp DNA fragment of the mouse Cd20 gene was amplified from cDNA derived from mouse Peyer’s patches by PCR using primers 5’- ACCCAGCAGCTGAGTAC ATCAAC-3’ (forward) and 5’- GAAATCATATCAATTTAAGA AGCAA-3’ (reverse) and subcloned into pGEM-T Easy vector (Promega, Southampton, UK). DIGoxigenin (DIG)-labeled sense and anti-sense RNA probes were synthesized using the DIG-RNA labeling kit with SP6 and T7 RNA polymerases (Roche Diagnostics, West Sussex, UK). Whole-mount in situ hybridization on Peyer’s patches was performed as described.35

Measurement of relative biological activities of PAMP in SFE. SFE from fecal pellets of individual mice were prepared as previously described.23 PAMP concentrations in SFE from young and aged mice were determined by measuring their capacity to induce NK-kB signaling in HEK-293 cells transfected with TLR4/MD2 or TLR5 as described. Briefly, TLR-deficient HEK-293 cells were transfected with 30 ng of human TLR4 (co-expressing MD2) or TLR5, 30 ng of CD14, 20 ng of renilla luciferase-reporter construct, and 10 ng of firefly luciferase-reporter construct driven by the NF-kB-dependent E-selectin promoter. Cell were cultivated in DMEM (Dulbecco’s modified Eagle’s medium) (Ambion, Warrington, UK) followed by treatment with DNase I (Ambion, Warrington, UK), and their details are provided in Supplementary Table S1 online. The cycle threshold values were determined using MxPro software (Stratagene) and normalized to the value of Actb.

ACKNOWLEDGEMENTS
We thank Simon Cumming, Megan Davye, Bob Fleming, Fraser Laing, and the Pathology Services Group (University of Edinburgh, UK) for excellent technical support. Helen Brown (University of Edinburgh, UK) for statistical advice, and Gaku Nakato (RCAI-RIKEN, Yokohama, Japan) for excellent technical advice and helpful discussion. This work was supported by project (BB/J014672/1) and Institute Strategic Program Grant (BB/ J0004332/1) funding from the Biotechnology and Biological Sciences Research Council. A.K. is supported by a Japan Society for the Promotion of Science Fellowship for Research Abroad and national sciences grant funding from the Mitsubishi Foundation.

DISCLOSURE
The authors declared no conflict of interest.
