Crossed product algebras and direct integral decomposition for Lie supergroups

Karl-Hermann Neeb*, Hadi Salmasian†

August 27, 2015

Abstract

For every finite dimensional Lie supergroup \((G, \mathfrak{g})\), we define a \(C^*\)-algebra \(A := A(G, \mathfrak{g})\), and show that there exists a canonical bijective correspondence between unitary representations of \((G, \mathfrak{g})\) and nondegenerate \(*\)-representations of \(A\). The proof of existence of such a correspondence relies on a subtle characterization of smoothing operators of unitary representations from [NSZ].

For a broad class of Lie supergroups, which includes nilpotent as well as classical simple ones, we prove that the associated \(C^*\)-algebra is CCR. In particular, we obtain the uniqueness of direct integral decomposition for unitary representations of these Lie supergroups.

1 Introduction

Unitary representations of Lie supergroups play an important role in the mathematical theory of SUSY quantum mechanics. One distinguished example of the role of these unitary representations is the classification of free relativistic super particles (see [FSZ] and [SaSt]), where a super analogue of the little group method of Mackey and Wigner is used.

Although the super version of the Mackey–Wigner method was used in the physics literature as early as the 1970’s, the problem of mathematical validity of this method in the context of supergroups was not addressed until less than a decade ago. This was done in [CCTV], where the authors remedy this issue by laying the mathematically rigorous foundations of the analytic theory of unitary representations of Lie supergroups, using the equivalence of categories between the category of Lie supergroups and the category of Harish-Chandra pairs [DeMo, Sec. 3.8], [Ko, Sec. 3.2]. The Harish-Chandra pair description of Lie supergroups will be explained in Definition 2.1 below.

The groundwork laid in [CCTV] has spawned research on the harmonic analysis of Lie supergroups. In particular, in [Sa] the irreducible unitary representations of a nilpotent Lie supergroup

*Department Mathematik, Friedrich-Alexander Universität Erlangen-Nürnberg, neeb@mi.uni-erlangen.de
†Department of Mathematics and Statistics, University of Ottawa, hsalmasi@uottawa.ca
are classified using an extension of Kirillov’s orbit method (see also \[NeSa\] Sec. 8]). For Lie supergroups corresponding to basic classical Lie superalgebras \[Mu\] Def. 1.14, the irreducible unitary representations are indeed highest weight modules \[NeSa\] Sec. 7], and therefore they are completely classified by the work done in \[J\].

The goal of this paper is to systematically study disintegration of arbitrary unitary representations of Lie supergroups into direct integrals of irreducible representations. To this end, for every finite dimensional Lie supergroup \((G, \mathfrak{g})\) we construct a \(C^*\)-algebra \(\mathcal{A} := \mathcal{A}(G, \mathfrak{g})\) whose nondegenerate \(*\)-representations are in bijective correspondence with unitary representations of \((G, \mathfrak{g})\). The \(C^*\)-algebra \(\mathcal{A}\) is obtained as the completion of a crossed product \(*\)-algebra \(\mathcal{A}^0\) that is associated to the action of \(G\) by left translation on the convolution algebra of test functions. Here indeed it will be more convenient to replace \(G\) by a slightly larger group \(G_\varepsilon \cong G \times \{1, \varepsilon\}\), as the action of the extra element \(\varepsilon\) will automatically keep track of the \(\mathbb{Z}_2\)-grading of the representation space. Starting from a unitary representation \((\pi, \rho^\varepsilon, \mathcal{H})\) of \((G, \mathfrak{g})\), we obtain a representation of \(\mathcal{A}\) by first extending \((\pi, \rho^\varepsilon, \mathcal{H})\) canonically to \(\mathcal{A}^0\), and then uniquely to a nondegenerate \(*\)-representation \((\hat{\pi}, \mathcal{H})\) of \(\mathcal{A}\) by continuity. Nevertheless, the construction of a representation of \((G, \mathfrak{g})\) from a representation \((\hat{\pi}, \mathcal{H})\) of \(\mathcal{A}\) is more subtle, because the standard method of extending \((\hat{\pi}, \mathcal{H})\) to the multiplier algebra \(M(\mathcal{A})\) does not work. Indeed the Lie superalgebra \(\mathfrak{g}\) does not act on \(\mathcal{A}\) by multipliers. To circumvent this issue, we use the extension of \((\hat{\pi}, \mathcal{H})\) to the multiplier algebra \(M(\mathcal{A}^0)\), and use the fact that \(G\) and \(\mathfrak{g}\) act on \(\mathcal{A}^0\) through \(M(\mathcal{A}^0)\). To complete the construction of the unitary representation of \((G, \mathfrak{g})\), we need to show that the action of \(\mathfrak{g}\) is indeed defined on \(\mathcal{H}^\infty\). To this end, we prove that \(\hat{\pi}(\mathcal{A}^0)\mathcal{H} = \mathcal{H}^\infty\), where \(\mathcal{H}^\infty\) denotes the space of smooth vectors of the action of \(G\) on \(\mathcal{H}\). The proof of the latter statement requires the Dixmier–Malliavin Theorem \([DM]\) and a subtle result from \([NSZ] Thm 2.11\) on the characterization of smoothing operators of unitary representations, that is, operators \(A : \mathcal{H} \to \mathcal{H}\) which map \(\mathcal{H}\) into \(\mathcal{H}^\infty\).

By the standard machinery of \(C^*\)-algebras \([Di]\), statements on the existence and uniqueness of disintegration of nondegenerate \(*\)-representations of \(\mathcal{A}\) can be transformed to similar statements on direct integral decompositions of unitary representations of \((G, \mathfrak{g})\). To obtain uniqueness of disintegration, it suffices to know that \(\mathcal{A}\) is CCR, that is, the image of every irreducible \(*\)-representation of \(\mathcal{A}\) lies in the algebra of compact operators. (Such \(C^*\)-algebras are sometimes called liminal.) We prove that \(\mathcal{A}\) is CCR for a broad class of Lie supergroups, which includes nilpotent Lie supergroups as well as those which correspond to classical simple Lie superalgebras (see \[Mu\] Sec. 1.3]). Therefore for the aforementioned classes of Lie supergroups, one obtains uniqueness of disintegration of unitary representations.

This article is organized as follows. Section 2 is devoted to definitions and basic properties of unitary representations that will be used in the rest of the paper. In Section 3 we define the crossed product \(*\)-algebra \(\mathcal{A}^0\). In Section 4 we construct the \(C^*\)-algebra \(\mathcal{A} := \mathcal{A}(G, \mathfrak{g})\) as the completion of the crossed product algebra \(\mathcal{A}^0\). In Section 5 we prove that under the \(G\)-action on \(\mathcal{A}\), orbit maps of elements of \(\mathcal{A}^0\) are smooth. In Section 6 we describe the canonical bijective correspondence between unitary representations of the Lie supergroup \((G, \mathfrak{g})\) and the (ungraded) nondegenerate \(*\)-representations of \(\mathcal{A}\). Finally, in Section 7 we give our liminality results for \(C^*\)-algebras of a broad
class of Lie supergroups, including the nilpotent and classical simple ones.

Acknowledgement. During the completion of this project, the second author was supported by an NSERC Discovery Grant and the Emerging Field Project “Quantum Geometry” of FAU Erlangen–Nürnberg. The authors thank the referee for useful comments and for pointing out the connection between the recent articles [Al] and [AHL] and our work.

2 Basic definitions

We begin by a rapid review of Lie supergroups (from the Harish-Chandra pair viewpoint) and their unitary representations. For a more elaborate reference, see [CCTV].

Throughout this paper, \( \mathbb{Z}/2\mathbb{Z} := \{0, 1\} \) denotes the field with two elements. If \( V = V_0 \oplus V_1 \) is a \( \mathbb{Z}/2\mathbb{Z} \)-graded vector space, then the parity of a homogeneous element \( x \in V \) is denoted by \( |x| \in \mathbb{Z}/2\mathbb{Z} \).

Definition 2.1. A Lie supergroup is an ordered pair \((G, \mathfrak{g})\) with the following properties.

(i) \( G \) is a Lie group.
(ii) \( \mathfrak{g} = \mathfrak{g}_0 \oplus \mathfrak{g}_1 \) is a Lie superalgebra over \( \mathbb{R} \).
(iii) \( \mathfrak{g}_0 \) is the Lie algebra of \( G \).
(iv) There exists a group homomorphism \( \text{Ad} : G \to \text{Aut}(\mathfrak{g}) \), defining a smooth action \( G \times \mathfrak{g} \to \mathfrak{g} \), such that

\[
\text{Ad}(g)x = dc_g(1)(x) \quad \text{and} \quad d\text{Ad}_y(1)(x) = [x, y]
\]

for every \( x \in \mathfrak{g}_0 \), \( y \in \mathfrak{g} \), and \( g \in G \), where \( c_g : G \to G \) is defined by \( c_g(g') := gg'g^{-1} \) and \( \text{Ad}_y : G \to \mathfrak{g} \) is defined by \( \text{Ad}_y(g) := \text{Ad}(g)y \).

In this article we assume that \( \dim \mathfrak{g} < \infty \), and the component group \( G/G^{\circ} \) is finite. The Lie supergroup \((G, \mathfrak{g})\) is called connected if \( G \) is a connected Lie group.

Remark 2.2. Here we should clarify that the condition given in Definition 2.1(iv) is identical to the ones given in our previous papers [NeSa2, Def. 4.6.3(iv)] and [NeSa3, Def. 7.1(iv)]. More precisely, in [NeSa2] and [NeSa3] we tacitly assume that \( \text{Ad} \) is an extension of the adjoint action of \( G \) on \( \mathfrak{g}_\mathbb{R} \).

Let \( (\pi, \mathcal{H}) \) be a unitary representation of a Lie group \( G \). For \( x \in \text{Lie}(G) \) and \( v \in \mathcal{H} \), we set

\[
d\pi(x)v := \lim_{t \to 0} \frac{1}{t} (\pi(e^{tx})v - v),
\]

whenever the limit exists. Here \( e^{tx} := \exp(tx) \) denotes the exponential map of \( G \).

Definition 2.3. Let \((G, \mathfrak{g})\) be a Lie supergroup. A unitary representation of \((G, \mathfrak{g})\) is a triple \((\pi, \rho, \mathcal{H})\) which satisfies the following properties.
(i) $\mathcal{H}$ has a $\mathbb{Z}/2\mathbb{Z}$-grading, that is, $\mathcal{H} = \mathcal{H}_0 \oplus \mathcal{H}_1$, and $(\pi, \mathcal{H})$ is a smooth unitary representation of $G$, such that $\pi(g)$ preserves the $\mathbb{Z}/2\mathbb{Z}$-grading of $\mathcal{H}$ for every $g \in G$.

(ii) $\rho^\pi : g \to \text{End}_C(\mathcal{H}^\infty)$ is a representation of the Lie superalgebra $g$, where $\mathcal{H}^\infty = \mathcal{H}_0^\infty \oplus \mathcal{H}_1^\infty$ is the subspace consisting of all $v \in \mathcal{H}$ for which the orbit map $G \to \mathcal{H}, \ g \mapsto \pi(g)v$ is smooth.

(iii) $\rho^\pi(x) = d\pi(x)|_{\mathcal{H}^\infty}$ for every $x \in g_T$.

(iv) For every $x \in g_1$, the operator $e^{-\frac{\pi i}{4}\rho^\pi(x)}$ is symmetric. That is, $-i\rho^\pi(x) \subseteq \rho^\pi(x)^*$. 

(v) $\pi(g)\rho^\pi(x)\pi(g)^{-1} = \rho^\pi(\text{Ad}(g)x)$ for every $g \in G$ and every $x \in g_T$.

Remark 2.4. By [NeSa3, Prop. 6.13], the condition given in Definition 2.3(v) follows from the weaker condition that for every element of the component group $G/G^\circ$, there exists a coset representative $g \in G$ such that $\pi(g)\rho^\pi(x)\pi(g)^{-1} = \rho^\pi(\text{Ad}(g)x)$ for every $x \in g$. 

Remark 2.5. As in [NeSa2, Def. 6.7.1], a unitary representation $(\pi, \rho^\pi, \mathcal{H})$ is called cyclic if there exists a vector $v \in \mathcal{H}_0^\infty$ such that $\pi(G)\rho^\pi(U(g_C))v$ spans a dense subspace of $\mathcal{H}$, where $g_C := g \otimes \mathbb{R}C$ and $U(g_C)$ denotes the universal enveloping algebra of $g_C$. A standard Zorn Lemma argument shows that every unitary representation can be written as a direct sum of representations which are cyclic up to parity change. Furthermore, in [NeSa2, Thm 6.7.5] a GNS construction is given which results in a correspondence between cyclic unitary representations and positive definite superfunctions of $(G, g)$.

Let $(\pi, \rho^\pi, \mathcal{H})$ be a unitary representation of $(G, g)$. We equip the space $\mathcal{H}^\infty$ with the Fréchet topology induced by the seminorms $v \mapsto \|d\pi(D)v\|$, for all $D \in U(g_0)$. This topology makes $\mathcal{H}^\infty$ a Fréchet space.

**Proposition 2.6.** For every $x \in g$, the map $\rho^\pi(x) : \mathcal{H}^\infty \to \mathcal{H}^\infty$ is continuous.

**Proof.** Continuity for $x \in g_0$ is standard, and therefore we will assume that $x \in g_T$. We need to prove that for every $x_1, \ldots x_\ell \in g_T$, for $D := x_1 \cdots x_\ell \in U(g_0)$, the map 

$$\mathcal{H}^\infty \to \mathbb{R}, \ v \mapsto \|d\pi(D)\rho^\pi(x)v\|$$

is continuous at $0 \in \mathcal{H}^\infty$. First assume that $\ell = 0$, so that $D = 1 \in U(g_0)$. In this case, continuity of (1) follows from the inequality 

$$\|\rho^\pi(x)v\|^2 = |\langle v, \rho^\pi(x)^2v \rangle| \leq \frac{1}{2}\|v\| \cdot \|d\pi([x, x])v\|$$
and the definition of the topology of $\mathcal{KH}^\infty$. To prove continuity of (1) for $\ell \geq 1$, we use the relation

$$x_1 \cdots x_\ell x = xx_1 \cdots x_\ell + \sum_{i=1}^{\ell} x_1 \cdots x_{i-1}[x_i, x]x_{i+1} \cdots x_\ell$$

and induction on $\ell$. \hfill $\square$

**Definition 2.7.** A multiplier of an associative algebra $A$ is a pair $(\lambda, \rho)$ of linear maps $A \to A$ which satisfy the relations

$$\lambda(ab) = \lambda(a)b, \quad \rho(ab) = a\rho(b), \quad \text{and} \quad a\lambda(b) = \rho(a)b$$

for every $a, b \in A$.

If $A$ is a $*$-algebra, then the multipliers of $A$ form a $*$-algebra, denoted by $M(A)$, with multiplication and involution defined by

$$(\lambda, \rho)(\lambda', \rho') := (\lambda\lambda', \rho'\rho) \quad \text{and} \quad (\lambda, \rho)^* := (\rho^*, \lambda^*),$$

where $\lambda^*(a) := \lambda(a^*)$ and $\rho^*(a) = \rho(a^*)$.

### 3 The crossed product $*$-algebra $A^\circ$

Fix a Lie supergroup $(G, \mathfrak{g})$. Set $G_\varepsilon := G \times \{1, \varepsilon\}$ such that $\varepsilon^2 = 1$, and define $\text{Ad}(\varepsilon)x := (-1)^{|x|}x$ for every homogeneous $x \in \mathfrak{g}$. We endow $G_\varepsilon$ with the product topology. Clearly $(G_\varepsilon, \mathfrak{g})$ is also a Lie supergroup. Let $\mathcal{D}(G_\varepsilon)$ be the convolution algebra of test functions (i.e., smooth compactly supported complex-valued functions) on $G_\varepsilon$. The convolution on $\mathcal{D}(G_\varepsilon)$ is defined by

$$(f_1 * f_2)(g') := \int_{G_\varepsilon} f_1(g)f_2(g^{-1}g')dg,$$

where $dg$ is the left-invariant Haar measure. The $*$-algebra structure is given by the involution

$$\tilde{f}(g) := \Delta(g)^{-1}f(g^{-1})$$

where $g \mapsto \Delta(g)$ is the modular function satisfying $d(gg') = \Delta(g')dg$. From now on, we set

$$L_g f(g') := f(g^{-1}g') \quad \text{and} \quad R_x f(g) := \lim_{t \to 0} \frac{1}{t} (L_{e^tx} f(g) - f(g)),$$

for $x \in \mathfrak{g}_\varepsilon$, $g, g' \in G_\varepsilon$, $f \in \mathcal{D}(G_\varepsilon)$, and $t \in \mathbb{R}$.  

Set $\mathfrak{g}_C := \mathfrak{g} \otimes_{\mathbb{R}} \mathbb{C}$. For every $g \in G_\varepsilon$, let $\alpha_g : U(\mathfrak{g}_C) \to U(\mathfrak{g}_C)$ denote the automorphism that is canonically induced by $\text{Ad}(g) : \mathfrak{g} \to \mathfrak{g}$. Our next goal is to define a crossed product $\ast$-algebra $\mathcal{A}^\circ = \mathcal{A}^\circ(G, \mathfrak{g})$. As a complex vector space,

$$\mathcal{A}^\circ := U(\mathfrak{g}_C) \otimes D(G_\varepsilon).$$

We identify $\mathcal{A}^\circ$ with a subspace of the vector space of $U(\mathfrak{g}_C)$-valued functions on $G_\varepsilon$ in the canonical way. Using this identification, we define a multiplication and a complex conjugation on $\mathcal{A}^\circ$ by the relations

$$(D_1 \otimes f_1)(D_2 \otimes f_2)(g') := \int_{G_\varepsilon} f_1(g)f_2(g^{-1}g')D_1\alpha_g(D_2)dg$$

and

$$(D \otimes f)^\ast(g) := \Delta(g^{-1})\overline{f(g^{-1})}\alpha_g(D^\dagger),$$

where the map $x \mapsto x^\dagger$ is the anti-linear anti-automorphism of $U(\mathfrak{g}_C)$ uniquely defined by

$$x^\dagger := \begin{cases} -x & \text{if } x \in \mathfrak{g}_0, \\ -ix & \text{if } x \in \mathfrak{g}_1. \end{cases}$$

In particular,

$$(D_1 \otimes f_1)(1 \otimes f_2) = D_1 \otimes (f_1 \ast f_2).$$

Every $g \in G_\varepsilon$ yields a multiplier $(\lambda_g, \rho_g)$ of $\mathcal{A}^\circ$ by setting

$$\lambda_g(D \otimes f) := \alpha_g(D) \otimes L_gf$$

and

$$\rho_g(D \otimes f) := D \otimes \Delta(g^{-1})R_{g^{-1}}f,$$

where $R_g f(g') := f(g'g)$. The algebra $\mathcal{A}^\circ$ is not necessarily unital. Nevertheless, we have the following lemma.

**Lemma 3.1.** Every $a \in \mathcal{A}^\circ$ can be written as a finite sum $a = a_1b_1 + \cdots + a_mb_m$, where $a_k, b_k \in \mathcal{A}^\circ$ for $1 \leq k \leq m$. In other words, $\mathcal{A}^\circ = \mathcal{A}^\circ\mathcal{A}^\circ$.

**Proof.** This follows from the more general result of [Al], Prop. 2.15, but we give a direct and simple argument. It is enough to prove the statement for $a = D \otimes f \in \mathcal{A}^\circ$. By the Dixmier–Malliavin Theorem [DM], we can write $f = f_1 \ast h_1 + \cdots + f_m \ast h_m$, where $f_1, \ldots, f_m, h_1, \ldots, h_m \in D(G_\varepsilon)$. It follows that $D \otimes f = (D \otimes f_1)(1 \otimes h_1) + \cdots + (D \otimes f_m)(1 \otimes h_m)$.

Every unitary representation $(\pi, \rho^\pi, \mathcal{H})$ of $(G, \mathfrak{g})$ extends to a unitary representation of $(G_\varepsilon, \mathfrak{g})$ by setting $\pi(\varepsilon)v = (-1)^{|v|}v$ for every homogeneous $v \in \mathcal{H}$. From now on, we assume that every unitary representation of $(G, \mathfrak{g})$ has been extended to $(G_\varepsilon, \mathfrak{g})$ as indicated above.

Fix a unitary representation $(\pi, \rho^\pi, \mathcal{H})$ of $(G, \mathfrak{g})$. Let $D \otimes f \in \mathcal{A}^\circ$, and as usual set

$$\pi(f) := \int_{G_\varepsilon} f(g)\pi(g)dg.$$
Note that $\|\pi(f)\| \leq \|f\|_{L^1}$. By Gårding’s Theorem we know that $\pi(f)\mathcal{H} \subseteq \mathcal{H}_\infty$, so that the linear map

$$\rho^\pi(D)\pi(f) : \mathcal{H} \to \mathcal{H}$$

is well-defined.

**Proposition 3.2.** Let $D \otimes f \in \mathcal{A}^\circ$. There exists a constant $M_{D \otimes f} > 0$ such that

$$\|\rho^\pi(D)\pi(f)\| \leq M_{D \otimes f}$$

for every unitary representation $(\pi, \rho^\pi, \mathcal{H})$ of $(G, \mathfrak{g})$.

**Proof.** Note that $\pi(g)\pi(f) = \pi(L_g f)$ for $g \in G_\epsilon$ and $f \in \mathcal{D}(G_\epsilon)$, and for $x \in \mathfrak{g}_\Gamma$ we have $\lim_{t \to 0} \|\frac{1}{t} (L_{e^{tx}} f - f) - R_x f\|_{L^1} = 0$. Thus for every $v \in \mathcal{H}$, we obtain that

$$d\pi(x)\pi(f)v = \lim_{t \to 0} \frac{1}{t} (\pi(e^{tx})\pi(f)v - \pi(f)v)$$

(7)

$$= \lim_{t \to 0} \frac{1}{t} (\pi(L_{e^{tx}} f)v - \pi(f)v) = \pi(R_x f)v.$$

By induction, from (7) it follows that

$$d\pi(D)\pi(f)v = \pi(R_D f)v \quad \text{for } D \in \mathcal{U}(\mathfrak{g}_\Gamma), \ f \in \mathcal{D}(G_\epsilon), \ \text{and } v \in \mathcal{H}.$$  

(8)

If $x \in \mathfrak{g}_\Gamma$, then from (7) it follows that

$$\|\rho^\pi(x)\pi(f)v\|^2 = \langle \rho^\pi(x)\pi(f)v, \rho^\pi(x)\pi(f)v \rangle = \frac{1}{2} |\langle \rho^\pi([x,x])\pi(f)v, \pi(f)v \rangle|$$

(9)

$$\leq \frac{1}{2} \|\rho^\pi([x,x])\pi(f)v\| \cdot \|\pi(f)v\| \leq \frac{1}{2} \|R_{[x,x]} f\|_{L^1} \cdot \|f\|_{L^1} \cdot \|v\|^2.$$

Similarly, if $x_1, \ldots, x_d \in \mathfrak{g}_\Gamma$ for some $d > 1$, then

$$\|\rho^\pi(x_1) \cdots \rho^\pi(x_d)\pi(f)v\|^2 = \langle \rho^\pi(x_1) \cdots \rho^\pi(x_d)\pi(f)v, \rho^\pi(x_1) \cdots \rho^\pi(x_d)\pi(f)v \rangle$$

$$\leq \frac{1}{2} \|\rho^\pi(x_1) \cdots \rho^\pi(x_d)\pi(f)v\| \cdot \|\rho^\pi([x_1, x_1])\rho^\pi(x_2) \cdots \rho^\pi(x_d)\pi(f)v\|.$$  

(10)

Furthermore,

$$\rho^\pi([x_1, x_1])\rho^\pi(x_2) \cdots \rho^\pi(x_d)\pi(f)v$$

(11)

$$= \sum_{j=2}^d \rho^\pi(x_2) \cdots \rho^\pi([x_1, x_1], x_j) \cdots \rho^\pi(x_d)\pi(f)v$$

$$+ \rho^\pi(x_2) \cdots \rho^\pi(x_d)\pi(R_{[x_1, x_1]} f)v.$$
By the PBW Theorem, it is enough to prove the statement of the proposition when
\[ D = y_1 \cdots y_\ell x_1 \cdots x_\ell, \]
where \( x_1, \ldots, x_\ell \in \mathfrak{g}_\mathbb{T} \) and \( y_1, \ldots, y_\ell \in \mathfrak{g}_\mathbb{T} \). From (8), (9), (10), and (11), and by induction on \( \ell' \), it follows that \( \| \rho^\pi(D) \pi(f) \| \) is bounded above by a constant which is expressible in terms of the \( L^1 \)-norms of derivatives of \( f \).

**Remark 3.3.** The crossed-product algebra \( \mathcal{A}^\circ \) is also considered in [Al] and [AHL]. Here we have introduced two new gadgets: the involution \( x \mapsto x^\dagger \), and the extension by \( \varepsilon \) which we will use below to keep track of the \( \mathbb{Z}/2\mathbb{Z} \)-grading of representations. The \( C^* \)-algebra \( \mathcal{A} := \mathcal{A}(G, \mathfrak{g}) \), which will be considered in Section 4, is closely related but not identical to the Fréchet algebra \( |\Omega|_c(G) \) defined in [Al]. The reader should note that Lemma 4.1 and the results of Section 6 are analogous to the results of [Al Sec. 2] and in particular [Al Prop. 2.15]. However, our results cannot be obtained as direct consequences of those in [Al], because a few technical issues arise that one needs to circumvent. In order to address these technical issues, and for the reader’s convenience, we provide detailed proofs.

### 4. The \( C^* \)-algebra \( \mathcal{A} := \mathcal{A}(G, \mathfrak{g}) \)

For a unitary representation \((\pi, \rho^\pi, \mathcal{H})\) of \((G, \mathfrak{g})\), we define the linear map \( \widehat{\pi} : \mathcal{A}^\circ \to B(\mathcal{H}) \) by setting
\[ \widehat{\pi}(D \otimes f) := \rho^\pi(D) \pi(f) \text{ for every } D \otimes f \in \mathcal{A}^\circ, \] (12)
and then extending \( \widehat{\pi} \) to \( \mathcal{A}^\circ \) by linearity. Consider the seminorm on \( \mathcal{A}^\circ \) defined by
\[ \|a\| := \sup_{(\pi, \rho^\pi, \mathcal{H})} \|\widehat{\pi}(a)\| \] (13)
where the supremum is taken over all unitary equivalence classes of cyclic unitary representations \((\pi, \rho^\pi, \mathcal{H}')\) of \((G, \mathfrak{g})\). From Proposition 3.2 it follows that \( \|a\| < \infty \).

**Lemma 4.1.** \( \widehat{\pi} \) is a \( * \)-representation of \( \mathcal{A}^\circ \).

**Proof.** This is the analogue of [Al Lem. 2.14]. First we prove that \( \widehat{\pi}(ab) = \widehat{\pi}(a) \widehat{\pi}(b) \) for every \( a, b \in \mathcal{A}^\circ \). It is enough to assume that \( a = D_1 \otimes f_1 \) and \( b = D_2 \otimes f_2 \). Choose \( \eta_1, \ldots, \eta_r \in C^\infty(G_\varepsilon) \) and \( E_1, \ldots, E_r \in \mathbf{U}(\mathfrak{g}_\varepsilon) \) such that \( \alpha_g(D_2) = \sum_i \eta_i(g) E_i \). Fix \( v \in \mathcal{H} \) and set \( w := \pi(f_2)v \). Then \( w \in \mathcal{H}^\infty \) and therefore the map \( G_\varepsilon \to \mathcal{H}^\infty, g \mapsto \pi(g)w \) is smooth [Po Prop. 2.1]. Using Proposition 2.6 we obtain
\[ \widehat{\pi}(a) \widehat{\pi}(b)v = \rho^\pi(D_1) \int_{G_\varepsilon} f_1(g) \pi(g) \rho^\pi(D_2) \pi(f_2) v dg \]
\[ = \rho^\pi(D_1) \sum_{i=1}^r \rho^\pi(E_i) \pi(\eta_if_1) \pi(f_2) v = \widehat{\pi} \left( \sum_{i=1}^r D_1 E_i \otimes (\eta_i f_1 \ast f_2) \right) v = \widehat{\pi}(ab)v. \]
The equality $\hat{\pi}(a)^* = \hat{\pi}(a^*)$ can be verified by a similar calculation, using the relation

$$\langle \rho^* (D \otimes f) v, w \rangle = \langle \rho^* (D) \pi(f) v, w \rangle = \langle v, \pi(\hat{f}) \rho^* (D^\dagger) w \rangle,$$

where $\hat{f}(g) = \Delta(g)^{-1} \bar{f}(g^{-1})$.

We are now ready to define $A := A(G, g)$. From Lemma 4.1 it follows that the map $a \mapsto a^*$ is an isometry of $A^0$ and $\|aa^*\| = \|a\|^2$. Set $A^0 := \{a \in A^0 : \|a\| = 0\}$ and let $A$ denote the completion of the quotient $A^0/A^0_\epsilon$ with respect to its induced norm. It is straightforward to check that $A$ is a $C^*$-algebra.

**Lemma 4.2.** Let $f \in D(G_\epsilon)$ and $D \otimes h \in A^\circ$. Then the map

$$\gamma_{f,D,h} : G_\epsilon \rightarrow A, \ g \mapsto f(g)\alpha_g(D) \otimes L_g h$$

is continuous and

$$\int_{G_\epsilon} \gamma_{f,D,h}(g) dg = (1 \otimes f)(D \otimes h). \quad (14)$$

**Proof.** Choose $E_1,\ldots,E_r \in \mathbf{U}(g_G^\circ)$ and $\eta_1,\ldots,\eta_r \in C^\infty(G_\epsilon)$ such that $\alpha_g(D) = \sum_{i=1}^r \eta_i(g)E_i$ for every $g \in G_\epsilon$. It follows that $\gamma_{f,D,h}(g) = \sum_{i=1}^r E_i \otimes f(g)\eta_i(g)L_g h$. Next we prove that, for every $1 \leq i \leq r$, the map $G_\epsilon \rightarrow A$, $g \mapsto E_i \otimes L_g h$ is continuous. Since we can replace $h$ by $L_g h$, it suffices to prove continuity at $1 \in G_\epsilon$. To this end, we need to show that

$$\lim_{g \rightarrow 1} \left( \sup_{(\pi,\rho,\pi^* \circ \varphi)} \| \rho^* (E_i) \pi(L_g h - h) \| \right) = 0.$$

By an argument similar to the proof of Proposition 3.2, the latter statement can be reduced to showing that $\lim_{g \rightarrow 1} \| R_D (L_g h - h) \|_{L^1} = 0$ for every $D \in \mathbf{U}(g_G^\circ)$. This is straightforward.

Next we prove (14). From (13) it follows that

$$(1 \otimes f)(D \otimes h)(g') = \sum_{i=1}^r \int_{G_\epsilon} f(g)(L_g h)(g') \eta_i(g)E_i dg = \sum_{i=1}^r (f \eta_i \ast h)(g')E_i. \quad (15)$$

The left-regular representation of $G_\epsilon$ on $L^1(G_\epsilon)$ is strongly continuous, and its integrated representation is given by convolution, that is, $\int_{G_\epsilon} f(g)L_g h \ dg = f \ast h$ for every $f, h \in L^1(G_\epsilon)$. We can now finish the proof by an argument similar to the one for [11 Eq. (2.13)]. More precisely, we have

$$\int_{G_\epsilon} \gamma_{f,D,h}(g) dg = \sum_{i=1}^r E_i \otimes \int_{G_\epsilon} f(g) \eta_i(g)L_g h \ dg = \sum_{i=1}^r E_i \otimes ((f \eta_i) \ast h). \quad (16)$$

Equality (14) now follows from (15) and (16). \qed
5 Multipliers of $\mathcal{A}$ and $\mathcal{A}^\circ$

For every $g \in G_\varepsilon$, let $(\lambda_g, \rho_g)$ be the multiplier of $\mathcal{A}^\circ$ that is defined in (6). It is straightforward to verify that $\lambda_g$ and $\rho_g$ are isometries of $\mathcal{A}^\circ$, and therefore the multiplier $(\lambda_g, \rho_g)$ extends uniquely to a multiplier of $\mathcal{A}$. For every $g \in G_\varepsilon$, the map

$$\eta_G(g) : \mathcal{A} \to \mathcal{A}, \ a \mapsto \lambda_g(a)$$

(17)

is an isometry and $\eta_G(gg') = \eta_G(g)\eta_G(g')$.

**Proposition 5.1.** For every $a \in \mathcal{A}^\circ$, the map

$$G \to \mathcal{A}, \ g \mapsto \eta_G(g)a$$

is smooth.

**Proof.** It suffices to prove that the orbit map of every $D \otimes f \in \mathcal{A}^\circ$ is smooth. Set

$$\hat{\pi}_u := \bigoplus_{(\pi, \rho^x, \mathcal{H})} \hat{\pi} \text{ and } (\pi_u, \mathcal{H}_u) := \bigoplus_{(\pi, \rho^x, \mathcal{H})} (\pi, \mathcal{H})$$

where the direct sums are over unitary equivalence classes of cyclic unitary representations of $(G, \mathfrak{g})$. Then $(\pi_u, \mathcal{H}_u)$ is a smooth unitary representation of $G_\varepsilon$, and the map $\hat{\pi}_u : \mathcal{A}^\circ \to B(\mathcal{H}_u)$ is an isometry. Furthermore, $\hat{\pi}_u(\eta_G(g)a) = \pi_u(g)\hat{\pi}_u(a)$ for $g \in G_\varepsilon$ and $a \in \mathcal{A}^\circ$. Consequently, to complete the proof it suffices to show that for every $a \in \mathcal{A}^\circ$, the map

$$G \to B(\mathcal{H}_u), \ g \mapsto \pi_u(g)\hat{\pi}_u(a).$$

is smooth. The latter statement is a consequence of [NSZ] Theorem 2.11. Indeed by [NSZ] Theorem 2.11 we need to verify that $\hat{\pi}_u(a)\mathcal{H} \subseteq \mathcal{H}^\infty$. Without loss of generality we can assume $a = D \otimes f$, and therefore $\hat{\pi}_u(a) = \rho^{\pi_u}(D)\pi_u(f)$. From Gårding’s Theorem and Definition (2.3)(ii), we obtain $\hat{\pi}_u(a)\mathcal{H} \subseteq \mathcal{H}^\infty$. \hfill $\square$

By [DoFe] Props. VIII.1.11/18, every multiplier of $\mathcal{A}$ is bounded and the multipliers of $\mathcal{A}$ form a unital Banach $*$-algebra $M(\mathcal{A})$ with multiplication and complex conjugation $\overline{}$ and the norm defined by $\|\lambda, \rho\| := \max\{\|\lambda\|, \|\rho\|\}$. Furthermore, the multipliers $(\lambda_g, \rho_g)$ for $g \in G_\varepsilon$ are unitary, that is,

$$(\lambda_g, \rho_g)\overline{(\lambda_g, \rho_g)} = 1 \in M(\mathcal{A}).$$

(18)
6 Nondegenerate ∗-representations of A

In this section we prove that the category of unitary representations of \((G, g)\) is isomorphic to the category of nondegenerate (in the sense of \[DoFe\, Def. \,V.1.7\]) ∗-representations of the C*-algebra \(A = A(G, g)\).

Proposition 6.1. Let \((\pi, \rho^\pi, \mathcal{H})\) be a unitary representation of a Lie supergroup \((G, g)\). Then the ∗-representation \(\hat{\pi}\) defined in Lemma 4.1 extends in a unique way to a nondegenerate ∗-representation \(\hat{\pi}: A \to B(\mathcal{H})\).

Proof. From (13) and Remark 2.5 it follows that \(|\hat{\pi}(a)| \leq |a|\) for every \(a \in A^\circ\). The existence and uniqueness of the extension \(\hat{\pi}: A \to B(\mathcal{H})\) now follows immediately. Nondegeneracy of \(\hat{\pi}\) follows from the equality \(\hat{\pi}(1 \otimes f) = \pi(f)\) for \(f \in D(G_\varepsilon)\).

We now give a construction of a unitary representation of \((G, g)\) from a nondegenerate ∗-representation \(\hat{\pi}: A \to B(\mathcal{H})\) of \(A\). By \[DoFe\, Prop. \,VIII.1.11\] and \[DoFe\, Prop. \,VIII.1.12\], there exists a unique extension of \(\hat{\pi}\) to a ∗-representation \(\hat{\pi}: M(A) \to B(\mathcal{H})\) of the multiplier algebra \(M(A)\) satisfying

\[
\hat{\pi}((\lambda, \rho))\hat{\pi}(a) = \hat{\pi}(\lambda(a)) \quad \text{for} \quad (\lambda, \rho) \in M(A) \text{ and } a \in A. \tag{19}
\]

Set

\[
\pi(g) := \hat{\pi}(\lambda_g, \rho_g) \quad \text{for every } g \in G_\varepsilon. \tag{20}
\]

From (18) it follows that

\[
\pi(g^{-1}) = \hat{\pi}((\lambda_g^{-1}, \rho_g^{-1})) = \hat{\pi}((\lambda_g, \rho_g)^*) = \hat{\pi}((\lambda_g, \rho_g)^*) = \pi(g)^*,
\]

that is, the operators \(\pi(g)\) are unitary. Furthermore, from (19) it follows that the subspace \(\mathcal{H}^\circ := \hat{\pi}(A^\circ)\mathcal{H}\) is invariant under \(\pi(g)\) for every \(g \in G_\varepsilon\).

Lemma 6.2. For every \(v \in \mathcal{H}\), the map \(G_\varepsilon \to \mathcal{H}, g \mapsto \pi(g)v\) is smooth if and only if \(v \in \mathcal{H}^\circ\). In particular, \((\pi, \mathcal{H})\) is a smooth unitary representation of \(G\).

Proof. The statement and proof are analogous to \[Al\, Prop. \,2.15\], but there are subtle technical differences, and therefore we provide a detailed argument. First we show that for every \(v \in \mathcal{H}^\circ\), the orbit map \(G_\varepsilon \to \mathcal{H}, g \mapsto \pi(g)v\) is smooth. Assume that \(v = \hat{\pi}(a)w\) for \(a \in A^\circ\) and \(w \in \mathcal{H}\). Then

\[
\pi(g)v = \hat{\pi}(\eta_G(g)a)w,
\]

where \(\eta_G(g) : A \to A\) is defined in (17). Since the map \(A \to \mathcal{H}, a \mapsto \hat{\pi}(a)w\) is continuous and linear, Proposition 5.1 implies that the orbit map \(g \mapsto \pi(g)v\) is smooth.
Next we observe that $H^\circ$ is a dense subspace of $H$, because $A^\circ$ is a dense subspace of $A$. Therefore the representation $(\pi, H)$ is smooth.

Finally, we prove that every smooth vector of $(\pi, H)$ belongs to $H^\circ$. By the Dixmier–Malliavin Theorem, it is enough to show that

$$\pi(f) = \widehat{\pi}(1 \otimes f) \text{ for every } f \in D(G_\varepsilon),$$

(21)

where $\pi(v) := \int_{G_\varepsilon} f(g)\pi(g)v \, dg$ for $v \in H$. Since both sides of (21) are bounded operators and $H^\circ$ is dense in $H$, it is enough to prove that

$$\pi(f)\widehat{\pi}(D \otimes h)v = \widehat{\pi}((1 \otimes f)(D \otimes h))v \text{ for } D \otimes h \in A^\circ \text{ and } v \in H.$$

Let $\gamma_{f,D,h}$ be defined as in Lemma 4.2. From (20) and (19) it follows that for every $v \in H$,

$$\pi(f)\widehat{\pi}(D \otimes h)v = \int_{G_\varepsilon} f(g)\pi(g)\widehat{\pi}(D \otimes h)v \, dg = \int_{G_\varepsilon} \widehat{\pi}(\gamma_{f,D,h}(g))v \, dg = \widehat{\pi}\left(\int_{G_\varepsilon} \gamma_{f,D,h}(g) \, dg\right)v,$$

and from (14) it follows that $\pi(f)\widehat{\pi}(D \otimes h)v = \widehat{\pi}((1 \otimes f)(D \otimes h))v$. \hfill \Box

Set

$$\pi^0(a) := \widehat{\pi}(a)|_{H^\circ} \text{ for every } a \in A^\circ.$$

From Lemma 3.1 and Lemma 6.2 it follows that $(\pi^0, H^\circ)$ is a non-degenerate $*$-representation of $A^\circ$ in the sense defined in [DoFe, Def. IV.3.17]. Therefore by [DoFe, Prop. VIII.1.9] there exists a unique extension of $\pi^0$ to a $*$-representation $\pi^0 : M(A^\circ) \to \text{End}_C(H^\circ)$ satisfying

$$\pi^0((\lambda, \rho))\pi^0(a) = \pi^0(\lambda a) \text{ for } (\lambda, \rho) \in M(A^\circ) \text{ and } a \in A^\circ.$$

From the latter equality, Lemma 3.1 and (19), it follows that $\pi^0((\lambda_g, \rho_g)) = \pi(g)|_{H^\circ}$ for every $g \in G_\varepsilon$.

For every $x \in g$, let $(\lambda_x, \rho_x) \in M(A^\circ)$ be the multiplier defined by

$$\lambda_x(D \otimes f) := xD \otimes f \text{ and } \rho_x(D \otimes f)(g) := f(g)D\alpha_{y}(x) \text{ for } g \in G_\varepsilon.$$

It is straightforward to verify that $(\lambda_x, \rho_x)^* = (\lambda_x^t, \rho_x^t)$ for every $x \in g$, where $x^t$ is defined as in (5). For every $x \in g$, we define a linear map

$$\rho^x : H^\circ \to H^\circ \text{, } v \mapsto \pi^0((\lambda_x, \rho_x))v.$$

(22)

Since $\pi(\varepsilon)^2 = 1$, we obtain a $\mathbb{Z}/2\mathbb{Z}$-grading $H = H_\uparrow \oplus H_\downarrow$ by the $\pm 1$ eigenspaces of $\pi(\varepsilon)$, i.e.

$$H_\uparrow := \{v \in H : \pi(\varepsilon)v = v\} \text{ and } H_\downarrow := \{v \in H : \pi(\varepsilon)v = -v\}.$$

Since $\pi(\varepsilon)$ leaves $H^\circ$ invariant, the $\mathbb{Z}/2\mathbb{Z}$-grading of $H$ induces a $\mathbb{Z}/2\mathbb{Z}$-grading $H^\circ = H_\uparrow^\circ \oplus H_\downarrow^\circ$ on $H^\circ$. We now prove the following proposition.
Proposition 6.3. \((\pi, \rho^\gamma, \mathcal{H})\) is a unitary representation of \((G, \mathfrak{g})\).

Proof. Every \(g \in G\) commutes with \(\varepsilon\), and therefore \(\pi(g)\) preserves the \(\mathbb{Z}/2\mathbb{Z}\)-grading of \(\mathcal{H}\). If \(x \in \mathfrak{g}_T\), then \((\lambda_x, \rho_x)^* = (\rho_{-ix}, \lambda_{-ix})\) in \(M(A^0)\), and it follows that the operator \(e^{-\frac{it}{2}} \rho^\gamma(x)\) is symmetric. For every \(x \in \mathfrak{g}\) and \(g \in G_\varepsilon\), we have

\[
(\lambda_g, \rho_g)(\lambda_x, \rho_x)(\lambda_g^{-1}, \rho_g^{-1}) = (\lambda_{\text{Ad}(g)x}, \rho_{\text{Ad}(g)x})
\]

and consequently,

\[
\pi(g)\rho^\gamma(x)\pi(g)^{-1} = \rho^\gamma(\text{Ad}(g)x).
\]  (23)

In particular, from (23) for \(g = \varepsilon\) it follows that \(\rho^\gamma(x) \in \text{End}_C(\mathcal{H}^\gamma)\) for \(x \in \mathfrak{g}_T\) and \(\rho^\gamma(x) \in \text{End}_C(\mathcal{H}^\gamma)\) for \(x \in \mathfrak{g}_\varepsilon\). The relation \(\rho^\gamma([x, y]) = [\rho^\gamma(x), \rho^\gamma(y)]\) for \(x, y \in \mathfrak{g}\) follows from the corresponding relation in the multiplier algebra \(M(A^0)\). Finally, we prove that \(\rho^\gamma(x) = d\pi(x)\big|_{\mathcal{H}^\gamma}\) for every \(x \in \mathfrak{g}_T\). Fix \(a \in A^0\) and \(v \in \mathcal{H}^\gamma\), and set

\[
\phi_{a,t} := \frac{1}{t}(\pi(e^{tx})\pi^\Omega(a)v - \pi^\Omega(a)v) - \rho^\gamma(x)\pi^\Omega(a)v \in \mathcal{H}.
\]

Then \(\phi_{a,t} = \pi^\Omega(a_t)v\), where \(a_t := \frac{1}{t}(\lambda_{\text{Ad}(a_t)} - a) - \lambda_x(a) \in A^0\). To complete the proof, we need to show that \(\lim_{t \to 0} \|\phi_{a,t}\| = 0\). But

\[
\|\phi_{a,t}\| = \|\pi^\Omega(a_t)v\| = \|\pi(a_t)v\| \leq \|a_t\| \cdot \|v\|
\]

and therefore it suffices to show that \(\lim_{t \to 0} \|a_t\| = 0\). Without loss of generality we can assume that \(a = D \otimes f\). From the definition of the norm of \(A\) we obtain

\[
\|a_t\| = \sup_{(\sigma, \rho^\sigma, \mathcal{H})} \left\| \frac{1}{t} (\sigma(e^{tx})\rho^\sigma(D)\sigma(f) - \rho^\sigma(D)\sigma(f) - \rho^\sigma(xD)\sigma(f)) \right\|,
\]

where the supremum is taken over all unitary equivalence classes of cyclic unitary representations \((\sigma, \rho^\sigma, \mathcal{H})\) of \((G, \mathfrak{g})\). Now fix a unitary representation \((\sigma, \rho^\sigma, \mathcal{H})\) and a vector \(v \in \mathcal{H}_{\sigma}\) such that \(\|v\| = 1\). By Taylor’s Theorem,

\[
\sigma(e^{tx})\rho^\sigma(D)\sigma(f)v = \rho^\sigma(D)\sigma(f)v + t\rho^\sigma(xD)\sigma(f)v + \frac{1}{2} \int_0^t(t-s)\sigma(e^{sx})\rho^\sigma(x^2D)\sigma(f)v\,ds.
\]

Proposition 3.2 implies that there exists a constant \(M > 0\), independent of \((\sigma, \rho^\sigma, \mathcal{H})\), such that \(\|\rho^\sigma(x^2D)\sigma(f)\| \leq M\). It follows that \(\|a_t\| \leq \frac{1}{2}M \cdot |t|\), and consequently \(\lim_{t \to 0} \|a_t\| = 0\). \(\square\)

Recall that the morphisms in the two categories of unitary representations of \((G, \mathfrak{g})\), and nondegenerate \(*\)-representations of \(A = A(G, \mathfrak{g})\), are bounded linear intertwining operators.
Theorem 6.4. The correspondences of Propositions 6.1 and 6.3 result in an isomorphism between the category of unitary representations of \((G, \mathfrak{g})\) and the category of nondegenerate \(*\)-representations of \(\mathcal{A} = \mathcal{A}(G, \mathfrak{g})\).

Proof. Step 1. First we verify that the correspondences of Proposition 6.1 and Proposition 6.3 are mutual inverses. Let \((\pi, \rho^\pi, \mathcal{H})\) be a unitary representation of \((G, \mathfrak{g})\). Let \(\hat{\pi}\) be the \(*\)-representation of \(\mathcal{A}\) constructed by Proposition 6.1 and \((\pi, \rho^\pi, \mathcal{H})\) be the unitary representation of \((G, \mathfrak{g})\) constructed from \(\hat{\pi}\) by Proposition 6.3. For \(D \otimes f \in \mathcal{A}^\circ\) and \(g \in G_\varepsilon\),

\[
\hat{\pi}(g)\hat{\pi}(D \otimes f) = \hat{\pi}(\lambda_g(D \otimes f)) = \hat{\pi}(\alpha_g(D) \otimes L_g f) = \rho^\pi(\alpha_g(D))\pi(L_g f) = \pi(g)\rho^\pi(D)\pi(f) = \pi(g)\hat{\pi}(D \otimes f).
\]

Since \(\pi(g)\) and \(\pi(g)\) are bounded operators and \(\hat{\pi}\) is nondegenerate, we obtain \(\pi(g) = \pi(g)\) for \(g \in G_\varepsilon\). Let \(\mathcal{H}^\infty\) denote the space of smooth vectors of \((\pi, \mathcal{H})\). For \(x \in \mathfrak{g}\), \(D \otimes f \in \mathcal{A}^\circ\), and \(w \in \mathcal{H}\),

\[
\rho^\pi(x)\hat{\pi}(D \otimes f)w = \hat{\pi}(xD \otimes f)w = \rho^\pi(x\pi(D)\pi(f)w = \rho^\pi(x)\hat{\pi}(D \otimes f)w.
\]

By the Dixmier–Malliavin Theorem, \(\mathcal{H}^\infty = \hat{\pi}(\mathcal{A}^\circ)\mathcal{H}\). Therefore (24) implies that \(\rho^\pi(x) = \rho^\pi(x)\) for every \(x \in \mathfrak{g}\).

Conversely, let \(\mathcal{H} : \mathcal{A} \rightarrow B(\mathcal{H})\) be a nondegenerate \(*\)-representation. Let \((\pi, \rho^\pi, \mathcal{H})\) be the unitary representation of \((G, \mathfrak{g})\) corresponding to \(\hat{\pi}\) by Proposition 6.3, and let \(\hat{\pi}' : \mathcal{A} \rightarrow B(\mathcal{H}'\mathcal{H})\) be the \(*\)-representation corresponding to \((\pi, \rho^\pi, \mathcal{H})\) by Proposition 6.1. For \(D_1 \otimes h_1 \in \mathcal{A}^\circ\), and \(w \in \mathcal{H}\), we obtain by Lemma 4.2 that

\[
\pi(f)\hat{\pi}(D_1 \otimes h_1)w = \int_{G_\varepsilon} f(g)\pi(g)\hat{\pi}(D_1 \otimes h_1)wdg
\]

(25)

\[
= \int_{G_\varepsilon} \hat{\pi}(\gamma_{f,D_1,h_1}(g))wdg = \hat{\pi}((\gamma_{f,D_1,h_1}(g))wdg = \hat{\pi}((1 \otimes f)(D_1 \otimes h_1))w.
\]

Now set \(a := D_1 \otimes h_1\). From (25) it follows that for every \(D \otimes f \in \mathcal{A}^\circ\),

\[
\hat{\pi}'(D \otimes f)\hat{\pi}(a)w = \rho^\pi(D)\pi(f)\hat{\pi}(a)w = \rho^\pi(D)\hat{\pi}((1 \otimes f)a)w = \hat{\pi}(D \otimes f)\hat{\pi}(a)w.
\]

Nondegeneracy of \(\hat{\pi}\) and boundedness of the operators \(\hat{\pi}'(D \otimes f)\) and \(\hat{\pi}(D \otimes f)\) imply that \(\hat{\pi}'(D \otimes f) = \hat{\pi}(D \otimes f)\). Since \(\mathcal{A}^\circ\) is dense in \(\mathcal{A}\), the equality \(\hat{\pi}'(a) = \hat{\pi}(a)\) holds for every \(a \in \mathcal{A}\).

Step 2. To complete the proof, we need to show that the correspondences of Proposition 6.1 and Proposition 6.3 are compatible with morphisms in the two categories. Suppose that \((\pi, \rho^\pi, \mathcal{H})\) and \((\sigma, \rho^\sigma, \mathcal{H}')\) are two unitary representations of \((G, \mathfrak{g})\), and let \(\hat{\pi} : \mathcal{A} \rightarrow B(\mathcal{H})\) and \(\hat{\sigma} : \mathcal{A} \rightarrow B(\mathcal{H}')\) be the \(*\)-representations of \(\mathcal{A}\) constructed from \((\pi, \rho^\pi, \mathcal{H})\) and \((\sigma, \rho^\sigma, \mathcal{H}')\) by Proposition 6.1. If
T : ℋ → ℋ is a (G, g)-intertwining operator, then it is easy to verify that T commutes with the action of ℋ on ℋ and ℋ, and therefore by a continuity argument, T commutes with the action of A on ℋ and ℋ as well.

Conversely, assume that T : ℋ → ℋ commutes with the actions of A on ℋ and ℋ. First note that for every \( \lambda, \rho \) ∈ \( \mathcal{A} \),

\[
T\hat{\pi}(\lambda, \rho)\hat{\pi}(a) = T\hat{\pi}(\lambda(a)) = \hat{\sigma}(\lambda(a))T = \hat{\sigma}(\lambda, \rho)T\hat{\pi}(a).
\]

Since \( \hat{\pi}(A)\mathcal{H} \) is a dense subspace of \( \mathcal{H} \), it follows that

\[
T\hat{\pi}(\lambda, \rho) = \hat{\sigma}(\lambda, \rho)T \text{ for every } (\lambda, \rho) ∈ M(\mathcal{A}).
\]

Setting \( (\lambda, \rho) := (\lambda_g, \rho_g) \) in the last relation, we obtain

\[
T\pi(g) = \sigma(g)T \text{ for every } g ∈ G_ε,
\]

and in particular \( T\mathcal{H}^∞ ⊂ \mathcal{H}^∞ \). From (26) for \( g = ε \), it follows that \( T \) preserves the \( \mathbb{Z}/2\mathbb{Z} \)-grading of \( \mathcal{H} \). Now for \( (\lambda, \rho) ∈ M(\mathcal{A}^0) \), \( a ∈ \mathcal{A}^0 \), and \( v ∈ \mathcal{H}^∞ \), using Lemma 6.2 we obtain that

\[
T\pi^0(\lambda, \rho)\pi^0(a)v = T\pi^0(\lambda(a))v = \sigma^0(\lambda(a))Tv = \sigma^0(\lambda, \rho)\sigma^0(a)Tv = \sigma^0(\lambda, \rho)T\pi^0(a)v.
\]

Thus Lemma 6.2 and Lemma 3.1 imply that \( T\pi^0(\lambda, \rho)w = \sigma^0(\lambda, \rho)Tw \) for every \( w ∈ \mathcal{H}^∞ \). Setting \( (\lambda, \rho) := (\lambda_x, \rho_x) \) for \( x ∈ g \), we obtain \( T\rho^x(x) = \rho^x(x)T \). Therefore \( T \) is a \( (G, g) \)-intertwining map from \( (\pi, \rho^0, \mathcal{H}) \) to \( (\sigma, \rho^0, \mathcal{H}) \).

\[\square\]

### 7 Unique direct integral decompositions

For a unitary representation \( (\pi, \rho^0, \mathcal{H}) \) of a Lie supergroup \( (G, g) \), it is desirable to have a decomposition as a direct integral of irreducible unitary representations. From Theorem 6.4 it follows that the problem of existence and uniqueness of such a direct integral decomposition can be reduced to the same problem for the associated \( C^* \)-algebra \( \mathcal{A} = \mathcal{A}(G, g) \).

In this section we prove that existence and uniqueness of direct integral decompositions hold for two general classes of Lie supergroups, which include nilpotent and basic classical Lie supergroups.

Recall that a \( C^* \)-algebra \( \mathcal{A} \) is called CCR if \( \hat{\pi}(A) \subseteq K(\mathcal{H}) \) for every irreducible \( * \)-representation \( \hat{\pi} : \mathcal{A} \to B(\mathcal{H}) \), where \( K(\mathcal{H}) \subseteq B(\mathcal{H}) \) denotes the subspace of compact operators. It is well known that for \( C^* \)-algebras which are CCR, existence and uniqueness of direct integral decompositions hold.

A unitary representation \( (\pi, \mathcal{H}) \) of a Lie group \( G \) is called completely continuous if \( \pi(f) ∈ K(\mathcal{H}) \) for every \( f ∈ \mathcal{D}(G) \).

**Theorem 7.1.** Let \( (G, g) \) be a Lie supergroup such that for every irreducible unitary representation \( (\pi, \rho^0, \mathcal{H}) \) of \( (G, g) \), the unitary representation \( (\pi, \mathcal{H}) \) of \( G \) is completely continuous. Then the \( C^* \)-algebra \( \mathcal{A} = \mathcal{A}(G, g) \) is CCR.
Step 1. Proof. We show that the hypotheses of Theorem 7.1 are satisfied.

Let \( \pi : \mathcal{A} \rightarrow B(\mathcal{H}) \) be an irreducible \( * \)-representation of \( \mathcal{A} \). Since \( K(\mathcal{H}) \) is a closed ideal of \( B(\mathcal{H}) \) and \( \| \hat{\pi}(a) \| \leq \| a \| \) for every \( a \in \mathcal{A} \), it suffices to prove that \( \hat{\pi}(D \otimes f) \in K(\mathcal{H}) \) for every \( D \otimes f \in \mathcal{A}^0 \). Let \( (\pi, \rho^\pi, \mathcal{H}) \) be the unitary representation of \((G, \mathfrak{g})\) that corresponds to \( \hat{\pi} \). Theorem 6.4 implies that \( (\pi, \rho^\pi, \mathcal{H}) \) is irreducible. The Dixmier–Malliavin Theorem implies that there exist \( f_1, \ldots, f_r, h_1, \ldots, h_r \in D(G_\varepsilon) \) such that \( f = \sum_{i=1}^r f_i \ast h_i \). Thus

\[
\hat{\pi}(D \otimes f) = \sum_{i=1}^r \hat{\pi}(D \otimes f_i)\hat{\pi}(1 \otimes h_i) = \sum_{i=1}^r \hat{\pi}(D \otimes f_i)\pi(h_i).
\]

From the assumption of the theorem it follows that \( \pi(h_i) \in K(\mathcal{H}) \) for \( 1 \leq i \leq r \). Consequently, \( \hat{\pi}(D \otimes f) \in K(\mathcal{H}) \).

As in \[Sa\], a Lie supergroup \((G, \mathfrak{g})\) is called nilpotent if \( \mathfrak{g} \) is a nilpotent Lie superalgebra.

Theorem 7.2. Let \((G, \mathfrak{g})\) be a connected nilpotent Lie supergroup. Then the \( C^* \)-algebra \( \mathcal{A} = \mathcal{A}(G, \mathfrak{g}) \) is CCR.

Proof. From \[Sa\] Cor. 6.1.1] it follows that the restriction of every irreducible unitary representation \((\pi, \rho^\pi, \mathcal{H})\) of \((G, \mathfrak{g})\) to \( G \) is a direct sum of finitely many irreducible unitary representations. Since every nilpotent Lie group is CCR \[Fe\], the unitary representation \((\pi, \mathcal{H})\) is completely continuous. Therefore Theorem 7.1 applies.

Recall from \[NeSa1\] that a Lie supergroup \((G, \mathfrak{g})\) is called \( * \)-reduced if for every nonzero \( x \in \mathfrak{g} \) there exists a unitary representation \((\pi, \rho^\pi, \mathcal{H})\) of \((G, \mathfrak{g})\) such that \( \rho^\pi(x) \neq 0 \).

Theorem 7.3. Let \((G, \mathfrak{g})\) be a connected Lie supergroup which is \( * \)-reduced and satisfies \( \mathfrak{g}_\mathcal{T} = [\mathfrak{g}_T, \mathfrak{g}_T] \). Then the \( C^* \)-algebra \( \mathcal{A} = \mathcal{A}(G, \mathfrak{g}) \) is CCR.

Proof. We show that the hypotheses of Theorem 7.1 are satisfied.

Step 1. From \[NeSa1\] Thm 7.3.2] it follows that there exists a compactly embedded (in the sense of \[Ne\] Def. VII.1.1]) Cartan subalgebra \( \mathfrak{t} \subseteq \mathfrak{g}_\mathcal{T} \) and a positive system \( \Delta^+ = \\{ \alpha_1, \ldots, \alpha_r \} \) of \( t \)-roots of \( \mathfrak{g} \), such that the space \( \mathcal{H}^t \) of \( t \)-finite smooth vectors in \( \mathcal{H} \) is a dense subspace of \( \mathcal{H} \). Furthermore, \( \mathcal{H}^t \) is an irreducible \( \mathfrak{g} \)-module which is a direct sum of \( t \)-weight spaces with weights of the form

\[
\lambda - \sum_{i=1}^r n_i \alpha_i \text{ where } n_i \in \mathbb{N} \cup \{0\} \text{ for every } 1 \leq i \leq r.
\]

Since \( \text{U}(\mathfrak{g}) \) is a finitely generated \( \text{U}(\mathfrak{g}_\mathcal{T}) \)-module, the irreducible (hence cyclic) \( \text{U}(\mathfrak{g}) \)-module \( \mathcal{H}^t \) is a finitely generated \( \text{U}(\mathfrak{g}_\mathcal{T}) \)-module. Since \( \text{U}(\mathfrak{g}_\mathcal{T}) \) is a Noetherian ring \[Di\] Cor. 2.3.8], it follows that \( \mathcal{H}^t \) is a Noetherian \( \text{U}(\mathfrak{g}_\mathcal{T}) \)-module.

Step 2. We prove that \((\pi, \mathcal{H})\) is a direct sum of finitely many irreducible unitary representations of \( G \). Assume the contrary. Then we can write \( \mathcal{H} = \bigoplus_{i=1}^\infty \mathcal{H}_i \) such that each \( \mathcal{H}_i \) is a \( G \)-invariant
closed subspace of \( \mathcal{H} \). From the inclusion \( \bigoplus_{i=1}^\infty \mathcal{H}_\ell^i \subseteq \mathcal{H}_\ell \) it follows that as a \( U(\mathfrak{g}_0) \)-module, \( \mathcal{H}_\ell \) is not Noetherian. This contradicts Step 1.

**Step 3.** From (27) and Step 2 it follows that \((\pi, \mathcal{H})\) is a direct sum of finitely many irreducible highest weight (in the sense of [Ne, Def. X.2.9]) unitary representations of \( G \). From [Ne, Thm X.4.10] it follows that every irreducible highest weight unitary representation of \( G \) is CCR. Thus \((\pi, \mathcal{H})\) is also a CCR unitary representation of \( G \).

Remark 7.4. Here it would be helpful to the reader to make a correction to [NeSa1, Thm 7.3.2]. The proof of [NeSa1, Thm 7.3.2] uses the bijective correspondence between \( G \)-invariant closed subspaces of \( \mathcal{H} \) and \( \mathfrak{g}_0 \)-invariant subspaces of analytic vectors in \( \mathcal{H} \). Such a bijection holds only when \( G \) is connected. Therefore connectedness of \( G \) should be added in the statement of [NeSa1, Thm 7.3.2]. It is plausible to expect that Theorem 7.3 holds when \( G \) has finitely many connected components.

Remark 7.5. Let \((G, \mathfrak{g})\) be a connected Lie supergroup such that \( \mathfrak{g} \) is a real form of a classical simple Lie superalgebra (see [Mu, Sec. 1.3]). That is, we assume that \( \mathfrak{g} \otimes \mathbb{R} \mathbb{C} \) is isomorphic to one of the Lie superalgebras of type \( \mathfrak{sl}(m|n) \) for \( m > n \geq 0 \), \( \mathfrak{psl}(m|m) \) for \( m \geq 1 \), \( \mathfrak{osp}(m|2n) \) for \( m, n \geq 0 \), \( D(2,1;\alpha) \) for \( \alpha \neq 0, -1 \), \( \mathfrak{p}(n) \) for \( n \geq 1 \), \( \mathfrak{q}(n) \) for \( n \geq 1 \), \( G(3) \), or \( F(4) \). Assume that \((G, \mathfrak{g})\) has nontrivial unitary representations. (A complete list of these Lie supergroups can be obtained from [NeSa1, Thm 6.2.1].) It is then straightforward to verify that \((G, \mathfrak{g})\) satisfies the hypotheses of Theorem 7.3 and therefore the \( C^* \)-algebra \( \mathcal{A} = \mathcal{A}(G, \mathfrak{g}) \) is CCR.
