Abstract

The theory of frames normal for general connections on differentiable bundles is developed. Links with the existing theory of frames normal for covariant derivative operators (linear connections) in vector bundles are revealed. The existence of bundle coordinates normal at a given point and/or along injective horizontal path is proved. A necessary and sufficient condition of existence of bundle coordinates normal along injective horizontal mappings is derived.
1. Introduction

Generally said, normal are called frames and coordinates in which the components of some geometrical object (locally) vanish; in particular, these can be the coefficients of a linear connection on a manifold or in vector bundle. As a result of that, some objects look like in a “flat” or “Euclidean” case, which significantly simplifies certain calculations, formulae, their interpretation, etc. For instance, the normal frames for linear connections turn to be the mathematical object for description of the inertial frames of reference in physics, in which some effects of a force field, like the gravity one, locally disappear.

The history of the theory of normal coordinates and frames goes back to 1854. The major classical results concerning the normal coordinates for linear connections are summarize in the table below.

| Year | Person    | Result and original reference                                                                 |
|------|-----------|-----------------------------------------------------------------------------------------------|
| 1854 | B. Riemann | Existence and construction of (‘Riemannian’) coordinates in a Riemannian manifold which are normal at a single point. [1] |
| 1922 | O. Veblen | Existence and construction of (‘Riemannian normal’) coordinates in a manifold with torsionless linear connection which are normal at a single point. [2] |
| 1922 | E. Fermi  | Existence of (‘Fermi’) coordinates in a Riemannian manifold which are normal along a path without self-intersections. [3] |
| 1926 | T. Levi-Civita | Explicit transformation to the Fermi coordinates along paths without self-intersections. [4] |
| 1927 | L. P. Eisenhart | Existence and construction of particular kind of (‘Fermi’) coordinates on a manifold with torsionless linear connection which are normal along a path without self-intersections. [5] |
| 1958 | L. O’Raifeartaigh | Necessary and sufficient conditions for existence of coordinates normal on submanifold of a manifold with torsionless linear connection. If such coordinates exist, a particular example of them (‘Fermi coordinates’) is constructed. [6] |

In [7–9] the normal frames were introduced and studied for derivations, in particular for linear connections, with generally non-vanishing curvature and torsion on a differentiable manifold. Then these objects were investigated for derivations and linear connections in vector bundles [10]. At last, the paper [11] explores them for linear transports along paths in vector bundles. The present work is devoted to the introduction and some properties of normal frames and coordinates for general connections on fibre bundles whose bundle and base spaces are differentiable manifolds.

The lay-out of the work is as follows.

In Sect. 2 is collected some introductory material needed for our exposition. Here some of our notation is fixed too.

Section 3 is devoted to the general connection theory on bundles whose base and bundles spaces are differentiable manifolds. In Subsect. 3.1 are reviewed some coordinates and frames/bases on the bundle space which are compatible with the fibre structure of a bundle. Subsect. 3.2 deals with the general connection theory. A connection on a bundle is defined as a distribution on its bundle space which is complimentary to the vertical distribution on it. The notion of specialized frame is introduced. Frames adapted to specialized frames, in particular to local bundle coordinates, are defined and the local (2-index) coefficients in them of a connection are defined and their transformation law is derived.
The theory of normal frames for connections on bundles is considered in sections 4–6. Sect. 4 deals with the general case. Loosely said, an adapted frame is called normal if in it vanish the 2-index coefficients of a connection on some set. It happens that a frame is normal if and only if it coincides with the frame it is adapted to. The set of these frames is completely described in the most general case. The problems of existence, uniqueness, etc. of normal frames adapted to holonomic frames, i.e. adapted to local coordinates, are discussed in Sect. 5. If such frames exist, their general form is described. The existence of frames normal at a given point and/or along an injective horizontal path is proved. The flatness of a connection on an open set is pointed as a necessary condition of existence of (locally) holonomic frames normal on that set. Some links between the general theory of normal frames and the existing one of normal frames in vector bundles are given in Sect. 6. It is proved that a frame is normal on a vector bundle with linear connection if and only if in it vanish the 3-index coefficients of the connection. The equivalence of the both theories on vector bundles is established.

Section 7 ends the paper with some concluding remarks.

In the Appendix is formulated and proved a necessary and sufficient condition for the existence of coordinates normal along injective mappings with non-vanishing horizontal component, in particular along injective horizontal mappings.

2. Preliminaries

This section contains an introductory material, notation etc. that will be needed for our exposition. The reader is referred for details to standard books on differential geometry, like [12–14].

A differentiable finite-dimensional manifold over a field $\mathbb{K}$ will be denoted typically by $M$. Here $\mathbb{K}$ stands for the field $\mathbb{R}$ of real or the field $\mathbb{C}$ of complex numbers, $\mathbb{K} = \mathbb{R}, \mathbb{C}$. The manifolds we consider are supposed to be smooth of class $C^2$. The sets of vector fields, realized as first order differential operators, over $M$ will be denoted by $\mathcal{X}(M)$. The space tangent to $M$ at $p \in M$ is $T_p(M)$ and $(T(M), \pi_T, M)$ will stand for the tangent bundle over $M$. The value of $X \in \mathcal{X}(M)$ at $p \in M$ is $X_p \in T_p(M)$.

If $M$ and $\tilde{M}$ are manifolds and $f: \tilde{M} \to M$ is a $C^1$ mapping, then $f_* := df: T(\tilde{M}) \to T(M)$ denotes the induced tangent mapping (or differential) of $f$ such that, for $p \in M$, $f_*|_p := df|_p: T_p(M) \to T_{f(p)}(M)$ and, for a $C^1$ function $g$ on $M$, $(f_*(X))(g) := X(g \circ f): p \mapsto f_*(X)(g) = X_p(g \circ f)$, with $\circ$ being the composition of mappings sign.

By $J \subseteq \mathbb{R}$ will be denoted an arbitrary real interval that can be open or closed at one or both its ends. The notation $\gamma: J \to M$ represents an arbitrary path in $M$. For a $C^1$ path $\gamma: J \to M$, the vector tangent to $\gamma$ at $s \in J$ will be denoted by $\dot{\gamma}(s) := \left. \frac{d}{dr} \gamma(r) \right|_{r=s}$.

Let the Greek indices $\lambda, \mu, \nu, \ldots$ run over the range $1, \ldots, \dim M$ and $\{E_\mu\}$ be a $C^1$ frame in $T(M)$, i.e. $E_\mu \in \mathcal{X}(M)$ be of class $C^1$ and, for each $p \in M$, the set $\{E_\mu|_p\}$ to be a basis of the vector space $T_p(M)$. The Einstein’s summation convention, summation on indices repeated on different levels over the whole range of their values, will be assumed hereafter.

---

1 Some of our definitions or/and results are valid also for $C^1$ or even $C^0$ manifolds, but we do not want to overload the material with continuous counting of the required degree of differentiability of the manifolds involved. Some parts of the text admit generalizations on more general spaces, like the topological ones, but this is out of the subject of the present work.

2 There are manifolds, like the even-dimensional spheres $S^{2k}$, $k \in \mathbb{N}$, which do not admit global, continuous (and moreover $C^k$ for $k \geq 1$), and nowhere vanishing vector fields [15]. If this is the case, the considerations must be localized over an open subset of $M$ on which such fields exist. We shall not overload our exposition with such details.
A frame \( \{E_{\mu}\} \) or its dual coframe \( \{E^{\mu}\} \) is called holonomic (anholonomic) if \( C_{\mu \nu}^{\lambda} = 0 \) (\( C_{\mu \nu}^{\lambda} \neq 0 \)) for all (some) values of the indices \( \mu, \nu, \) and \( \lambda \), where the functions \( C_{\mu \nu}^{\lambda} \) are defined by \( [E_{\mu}, E_{\nu}] := E_{\rho} \circ E_{\mu} - E_{\rho} \circ E_{\nu} =: C_{\mu \rho}^{\lambda} E_{\lambda} \); these functions are a measure of deviation from a holonomic frame and are known as the components of the anholonomy object of \( \{E_{\mu}\} \). For a holonomic frame always exist local coordinates \( \{x^{\mu}\} \) on \( M \) such that locally \( E_{\mu} = \frac{\partial}{\partial x^{\mu}} \) and \( E^{\mu} = dx^{\mu} \). Conversely, if \( \{x^{\mu}\} \) are local coordinates on \( M \), then the local frame \( \{\frac{\partial}{\partial x^{\mu}}\} \) and local coframe \( \{dx^{\mu}\} \) are defined and holonomic on the domain of \( \{x^{\mu}\} \).

If \( n \in \mathbb{N} \) and \( n \leq \text{dim} \, M \), an \( n \)-dimensional distribution \( \Delta \) on \( M \) is defined as a mapping \( \Delta : p \mapsto \Delta_{p} \) assigning to each \( p \in M \) an \( n \)-dimensional subspace \( \Delta_{p} \) of the tangent space \( T_{p}(M) \) of \( M \) at \( p \), \( \Delta_{p} \subseteq T_{p}(M) \). A distribution is integrable if there is a submersion \( \psi : M \to N \) such that \( \text{Ker} \, \psi_{*} = \Delta; \) a necessary and locally sufficient condition for the integrability of \( \Delta \) is the commutator of every two vector fields in \( \Delta \) to be in \( \Delta \). We say that a vector field \( X \in \mathcal{X}(M) \) is in \( \Delta \) and write \( X \in \Delta \), if \( X_{p} \in \Delta_{p} \) for all \( p \in M \). A basis on \( U \subseteq M \) for \( \Delta \) is a set \( \{X_{1}, \ldots, X_{n}\} \) of \( n \) linearly independent (relative to functions \( U \to \mathbb{K} \)) vector fields in \( \Delta|_{U} \), i.e. \( \{X_{1}|_{p}, \ldots, X_{n}|_{p}\} \) is a basis for \( \Delta_{p} \) for all \( p \in U \).

A distribution is convenient to be described in terms of (global) frames or and coframes over \( M \). In fact, if \( p \in M \) and \( g = 1, \ldots, n \), in each \( \Delta_{p} \subseteq T_{p}(M) \), we can choose a basis \( \{X_{g}|_{p}\} \) and hence a frame \( \{X_{g}\}, X_{g} : p \mapsto X_{g}|_{p}, \) in \( \{\Delta_{p} : p \in M\} \subseteq T(M) \); we say that \( \{X_{g}\} \) is a basis for/\in \( \Delta \). Conversely, any collection of \( n \) linearly independent (relative to functions \( M \to \mathbb{K} \)) vector fields \( X_{g} \) on \( M \) defines a distribution \( p \mapsto \{\sum_{g=1}^{n} f^{g} X_{g}|_{p} : f^{g} \in \mathbb{K}\} \). Consequently, a frame in \( T(M) \) can be formed by adding to a basis for \( \Delta \) a set of \((\text{dim} \, M - n)\) new linearly independent vector fields (forming a frame in \( T(M) \setminus \{\Delta_{p} : p \in M\}\) and v.v., by selecting \( n \) linearly independent vector fields on \( M \), we can define a distribution \( \Delta \) on \( M \).

3. Connections on bundles

Before presenting the general connection theory in Subsect. 3.2, we at first fix some notation and concepts concerning fibre bundles in Subsect. 3.3.

3.1. Coordinates and frames on the bundle space

Let \((E, \pi, M)\) be a bundle with bundle space \( E \), projection \( \pi : E \to M \), and base space \( M \). We suppose that the spaces \( E \) and \( M \) are \( C^{2} \), differentiable, if the opposite is not stated explicitly, \(^{3}\) manifolds of finite dimensions \( n \in \mathbb{N} \) and \( n + r \), for some \( r \in \mathbb{N} \), respectively; so the dimension of the fibres \( \pi^{-1}(x) \), with \( x \in M \), i.e. the fibre dimensions of \((E, \pi, M)\), is \( r \).

Let the Greek indices \( \lambda, \mu, \nu, \ldots \) run from 1 to \( n = \text{dim} \, M \), the Latin indices \( a, b, c, \ldots \) take the values from \( n + 1 \) to \( n + r = \text{dim} \, E \), and the uppercase Latin indices \( I, J, K, \ldots \) take values in the whole set \( \{1, \ldots, n + r\} \). One may call these types of indices respectively base, fibre, and bundle indices.

Suppose \( \{u^{\mu}\} = \{u^{a}, u^{v}\} = \{u^{1}, \ldots, u^{n+r}\} \) are local bundle coordinates on an open set \( U \subseteq E \), i.e. on the set \( \pi(U) \subseteq M \) there are local coordinates \( \{x^{\mu}\} \) such that \( u^{\mu} = x^{\mu} \circ \pi; \) the coordinates \( \{u^{\mu}\} \) (resp. \( \{u^{a}\} \)) are called basic (resp. fibre) coordinates \(^{14}\).

---

\(^{3}\) Most of our considerations are valid also if \( C^{1} \) differentiability is assumed and even some of them hold on \( C^{0} \) manifolds. By assuming \( C^{2} \) differentiability, we skip the problem of counting the required differentiability class of the whole material that follows. Sometimes, the \( C^{2} \) differentiability is required explicitly, which is a hint that a statement or definition is not valid otherwise. If we want to emphasize that some text is valid under a \( C^{1} \) differentiability assumption, we indicate that fact explicitly. However, the proofs of lemmas \(^{5,4}\) and \(^{4}\) proposition \(^{5}\) and all assertions in section \(^{6}\) require \( C^{3} \) differentiability, which will be indicated explicitly.

\(^{4}\) If \((U, v)\) is a bundle chart, with \( v : U \to \mathbb{K}^{n} \times \mathbb{K}^{r} \) and \( c^{a} : \mathbb{K}^{r} \to \mathbb{K} \) are such that \( c^{a}(c_{1}, \ldots, c_{r}) = c_{a} \in \mathbb{K} \), then one can put \( u^{a} = c^{a} \circ pr_{2} \circ v \), where \( pr_{2} : \mathbb{K}^{n} \times \mathbb{K}^{r} \to \mathbb{K}^{r} \) is the projection on the second multiplier \( \mathbb{K}^{r} \).
Further only coordinate changes

\[ \{u^\mu, u^a\} \mapsto \{\tilde{u}^\mu, \tilde{u}^a\} \] (3.1a)
on E which respect the fibre structure, viz. the division into basic and fibre coordinates, will be considered; this means that

\[
\begin{align*}
\tilde{u}^\mu(p) &= f^\mu(u^1(p), \ldots, u^n(p)) \\
\tilde{u}^a(p) &= f^a(u^1(p), \ldots, u^n(p), u^{n+1}(p), \ldots, u^{n+r}(p))
\end{align*}
\] (3.1b)

for \( p \in E \) and some functions \( f^I \). The bundle coordinates \( \{u^\mu, u^a\} \) induce the (local) frame \( \{\partial_\mu := \frac{\partial}{\partial u^\mu}, \partial_a := \frac{\partial}{\partial u^a}\} \) over \( U \) in the tangent bundle space \( T(E) \) of the tangent bundle over the bundle space \( E \). Since a change \( \{3.1\} \) of the coordinates on \( E \) implies \( \partial_I \mapsto \tilde{\partial}_I := \frac{\partial}{\partial u^\mu} = \frac{\partial u^I}{\partial \tilde{u}^\mu} \partial_J \), the transformation \( \{3.1\} \) leads to

\[
(\partial_\mu, \partial_a) \mapsto (\tilde{\partial}_\mu, \tilde{\partial}_a) = (\partial_\nu, \partial_b) \cdot A
\]

(3.2)

Here expressions like \( (\partial_\mu, \partial_a) \) are shortcuts for ordered \((n + r)\)-tuples like \((\partial_1, \ldots, \partial_{n+r}) = ([\partial_\mu]_{\mu=1}^n, [\partial_a]_{a=n+1}^{n+r})\), the centered dot \( \cdot \) stands for the matrix multiplication, and the transformation matrix \( A \) is

\[
A := \left[ \frac{\partial u^I}{\partial \tilde{u}^J} \right]_{I,J=1}^{n+r} = \begin{pmatrix}
[\partial_\mu] & 0_{n \times r} \\
[\partial_a] & 0_{r \times r}
\end{pmatrix} = \begin{pmatrix}
[\partial_\mu] & 0 \\
[\partial_a] & 0
\end{pmatrix}
\]

(3.3)

where \( 0_{n \times r} \) is the \( n \times r \) zero matrix. The explicit form of the matrix inverse to \( \{3.3\} \) is \( A^{-1} = \left[ \frac{\partial \tilde{u}^J}{\partial u^I} \right] = \ldots \) and it is obtained from \( \{3.3\} \) via the change \( u \leftrightarrow \tilde{u} \).

The formula \( \{3.2\} \) can be generalized for arbitrary frame \( \{e_I\} = \{e_\mu, e_a\} \) in \( T(E) \) which respect the fibre structure in a sense that their admissible changes are given by

\[
(e_I) = (e_\mu, e_a) \mapsto (\tilde{e}_I) = (\tilde{e}_\mu, \tilde{e}_a) = (e_\nu, e_b) \cdot A
\]

(3.4)

Here \( A = \left[ A^I_J \right] \) is a nondegenerate matrix-valued function with a block structure similar to \( \{3.3\} \), viz.

\[
A = \left[ \begin{array}{c|c}
[A^\mu]_{\mu=1}^n & 0_{n \times r} \\
\hline
[A_a]_{a=1}^{n+r} & [A^b]_{b=n+1}^{n+r}
\end{array} \right] = \begin{pmatrix}
A^\mu & 0 \\
A_a & A^b
\end{pmatrix}
\]

(3.5a)

with inverse matrix

\[
A^{-1} = \begin{pmatrix}
[A^\mu]^{-1} & 0 \\
[A_a]^{-1} \cdot [A^\mu]^{-1} & [A^b]^{-1}
\end{pmatrix}
\]

(3.5b)

Here \( A^a_a : U \to K \) and \( [A^\mu] \) and \( [A^a]^{-1} \) are non-degenerate matrix-valued functions on \( U \) such that \( [A^\mu] \) is constant on the fibres of \( E \), i.e., for \( p \in E \), \( A^\nu_\mu(p) \) depends only on \( \pi(p) \in M \), which is equivalent to any one of the equations \( A^\nu_\mu = D^\nu_\mu \circ \pi \) and \( \frac{\partial A^\nu_\mu}{\partial u^a} = 0 \), with \( [B^\mu] \) being a nondegenerate matrix-valued function on \( \pi(U) \subseteq M \). Obviously, \( \{3.2\} \) corresponds to \( \{3.1\} \) with \( e_I = \frac{\partial}{\partial u^I}, \tilde{e}_I = \frac{\partial}{\partial \tilde{u}^I}, \) and \( A_I^J = \frac{\partial u^I}{\partial \tilde{u}^J} \).

All frames on \( E \) connected via \( \{3.1\} \)–\( \{3.3\} \), which are (locally) obtainable from holonomic ones, induced by bundle coordinates, via admissible changes, will be referred as bundle frames.
3.2. Connection theory

From a number of equivalent definitions of a connection on differentiable manifold [16, sections 2.1 and 2.2], we shall use the following one.

**Definition 3.1.** A connection on a bundle \((E, \pi, M)\) is an \(n = \dim M\) dimensional distribution \(\Delta^h\) on \(E\) such that, for each \(p \in E\) and the vertical distribution \(\Delta^v\) defined by

\[
\Delta^v: p \mapsto \Delta^v_p := T_{\pi(p)}(\pi^{-1}(\pi(p))) \cong T_p(\pi^{-1}(\pi(p))),
\]

with \(\pi^{-1}(\pi(p)) \to E\) being the inclusion mapping, is fulfilled

\[
\Delta^v \oplus \Delta^h = T_p(E),
\]

where \(\Delta^h: p \mapsto \Delta^h_p \subseteq T_p(\pi^{-1}(\pi(p)))\) and \(\oplus\) is the direct sum sign. The distribution \(\Delta^h\) is called horizontal and symbolically we write \(\Delta^v \oplus \Delta^h = T(E)\).

A vector at a point \(p \in E\) (resp. a vector field on \(E\)) is said to be vertical or horizontal if it (resp. its value at \(p\)) belongs to \(\Delta^h_p\) or \(\Delta^v_p\), respectively, for the given (resp. any) point \(p\). A vector \(Y_p \in T_p(E)\) (resp. vector field \(Y \in \mathcal{X}(E)\)) is called a horizontal lift of a vector \(X_{\pi(p)} \in T_{\pi(p)}(M)\) (resp. vector field \(X \in \mathcal{X}(M)\) on \(M = \pi(E)\)) if \(\pi_*(Y_p) = X_{\pi(p)}\) for the given (resp. any) point \(p \in E\). Since \(\pi_*|_{\Delta^h}: \Delta^h \to T_{\pi(p)}(M)\) is a vector space isomorphism for all \(p \in E\) [14, sec. 1.24], any vector in \(T_{\pi(p)}(M)\) (resp. vector field in \(\mathcal{X}(M)\)) has a unique horizontal lift in \(T_p(E)\) (resp. \(\mathcal{X}(E)\)).

As a result of [16, sec. 1.24], any vector \(Y_p \in T_p(E)\) (resp. vector field \(Y \in \mathcal{X}(E)\)) admits a unique representation \(Y_p = Y^v_p \oplus Y^h_p\) (resp. \(Y = Y^v \oplus Y^h\)) with \(Y^v_p \in \Delta^v_p\) and \(Y^h_p \in \Delta^h_p\) (resp. \(Y^v \in \Delta^v\) and \(Y^h \in \Delta^h\)). If the distribution \(p \mapsto \Delta^h_p\) is differentiable of class \(C^m\), \(m \in \mathbb{N} \cup \{0, \infty, \omega\}\), it is said that the connection \(\Delta^h\) is (differentiable) of class \(C^m\). A connection \(\Delta^h\) is of class \(C^m\) if and only if, for every \(C^m\) vector field \(Y\) on \(E\), the vertical \(Y^v\) and horizontal \(Y^h\) vector fields are of class \(C^m\).

Let us now look on a connections \(\Delta^h\) on a bundle \((E, \pi, M)\) from a view point of (local) frames and their dual coframes on \(E\). Let \(\{e_\mu\}\) be a basis for \(\Delta^h\), i.e. \(e_\mu \in \Delta^h\) and \(\{e_\mu|_p\}\) is a basis for \(\Delta^h_p\) for all \(p \in E\).

**Definition 3.2.** A frame \(\{e_\ell\}\) in \(T(E)\) over \(E\) is called specialized for a connection \(\Delta^h\) if the first \(n = \dim M\) of its vector fields \(\{e_\mu\}\) form a basis for the horizontal distribution \(\Delta^h\) and its last \(r = \dim \pi^{-1}(x), x \in M\), vector fields \(\{e_a\}\) form a basis for the vertical distribution \(\Delta^v\).

It is a simple, but important, fact that the specialized frames are the most general ones which respect the splitting of \(T(E)\) into vertical and horizontal components. Suppose \(\{e_\ell\}\) is a specialized frame. Then the general element of the set of all specialized frames is (see (3.3))

\[
(e_\ell, e_a) = (e_\nu, e_b) \cdot \begin{bmatrix} A^\nu_{\mu} & 0 \\ 0 & A^b_a \end{bmatrix} = (A^\nu_{\mu}e_\nu, A^b_ae_b),
\]

where \([A^\nu_{\mu}]_{\nu=1}^{n}\) and \([A^b_a]_{a=1}^{n+1}\) are non-degenerate matrix-valued functions on \(E\), which are constant on the fibres of \((E, \pi, M)\), i.e. we can set \(A^\nu_{\mu} = B^\nu_{\mu} \circ \pi\) and \(A^b_a = B^b_a \circ \pi\) for some non-degenerate matrix-valued functions \([B^\nu_{\mu}]\) and \([B^b_a]\) on \(M\).

Since \(\pi_*|_{\Delta^h}: \{X \in \Delta^h\} \to \mathcal{X}(M)\) is an isomorphism, any basis \(\{e_\mu\}\) for \(\Delta^h\) defines a basis \(\{E_\mu\}\) of \(\mathcal{X}(M)\) such that

\[
E_\mu = \pi_*|_{\Delta^h}(e_\mu)
\]
and v.v., a basis \{E_\mu\} for \mathcal{X}(M) induces a basis \{\varepsilon_\mu\} for \Delta^h via
\[
\varepsilon_\mu = (\pi_*|_{\Delta^h})^{-1}(E_\mu).
\] (3.10)
Thus a ‘horizontal’ change
\[
\varepsilon_\mu \mapsto \bar{\varepsilon}_\mu = (B^\nu_\mu \circ \pi)\varepsilon_\nu,
\] (3.11)
which is independent of a ‘vertical’ one given by
\[
\varepsilon_a \mapsto \bar{\varepsilon}_a = (B^b_a \circ \pi)\varepsilon_b
\] (3.12)
with \{\varepsilon_a\} being a basis for \Delta^v, is equivalent to the transformation
\[
E_\mu \mapsto \bar{E}_\mu = B^\nu_\mu E_\nu
\] (3.13)
of the basis \{E_\mu\} for \mathcal{X}(M), related via (3.9) to the basis \{\varepsilon_\mu\} for \Delta^h. Here [B^\nu_\mu] and [B^b_a] are non-degenerate matrix-valued functions on \(M\).

As \pi_* (\varepsilon_a) = 0 \in \mathcal{X}(M), the ‘vertical’ transformations (3.12) do not admit interpretation analogous to the ‘horizontal’ ones (3.11). However, in a case of a vector bundle \((E, \pi, M)\), they are tantamount to changes of frames in the bundle space \(E\), i.e. of the bases for \text{Sec}(E, \pi, M). Indeed, if \(v\) is a mapping defined by
\[
v: \text{Sec}(E, \pi, M) \to \{\text{vector fields in } \Delta^v\}
\]
\[
v: Y \mapsto Y^v: p \mapsto Y^v|_p := \frac{d}{dt} \bigg|_{t=0}(p + tY_{\pi(p)}),
\] (3.14)
which mapping is a linear isomorphism [14], the sections
\[
E_a = v^{-1} (\varepsilon_a)
\] (3.15)
form a basis for \text{Sec}(E, \pi, M) as the vertical vector fields \varepsilon_a form a basis for \Delta^v. Conversely, any basis \{E_a\} for the sections of \((E, \pi, M)\) induces a basis \{\varepsilon_a\} for \Delta^v such that
\[
\varepsilon_a = v(E_a).
\] (3.16)
As \(v\) and \(v^{-1}\) are linear, the change (3.12) is equivalent to the transformation
\[
E_a \mapsto \bar{E}_a = B^b_a E_b
\] (3.17)
of the frame \{E_a\} in \(E\) related to \{\varepsilon_a\} via (3.15). In this way, we see that any specialized frame \{\varepsilon_I\} = \{\varepsilon_\mu, \varepsilon_a\} for a connection on a vector bundle \((E, \pi, M)\) is equivalent to a pair of frames \{(E_\mu), (E_a)\} such that \{E_\mu\} is a basis for the set \mathcal{X}(M) of vector fields on the base \(M\), i.e. for the sections of the tangent bundle \((T(M), \pi_T, M)\) (and hence is a frame in \(T(M)\) over \(M\), and \{E_a\} is a basis for the set \text{Sec}(E, \pi, M) of sections of the initial bundle (and hence is a frame in \(E\) over \(M\)). Since conceptually the frames in \(T(M)\) and \(E\) are easier to understand and in some cases have a direct physical interpretation, one often works with the pair of frames \{(E_\mu = \pi_*|_{\Delta^h} (\varepsilon_\mu)), (E_a = v^{-1} (\varepsilon_a))\} instead with a specialized frame \{\varepsilon_I\} = \{\varepsilon_\mu, \varepsilon_a\}; for instance \{E_\mu\} and \{E_a\} can be completely arbitrary frames in \(T(M)\) and \(E\), respectively, while the specialized frames represent only a particular class of frames in \(T(E)\).

One can mutatis mutandis localize the above considerations when \(M\) is replaced with an open subset \(U_M\) in \(M\) and \(E\) is replaced with \(U = \pi^{-1}(U_M)\). Such a localization is important when the bases/frames considered are connected with some local coordinates or when they should be smooth.\(^5\)

\(^5\) Recall, not every manifold admits a global nowhere vanishing \(C^m\), \(m \geq 0\), vector field (see [15] or [17, sec. 4.24]); e.g. such are the even-dimensional spheres \(S^{2k}\), \(k \in \mathbb{N}\), in Euclidean space.
Let \( \{e_I\} \) be a frame in \( T(E) \) defined over an open set \( U \subseteq E \) and such that \( \{e_a|_p\} \) is a basis for the space \( T_p(\pi^{-1}(\pi(p))) \) tangent to the fibre through \( p \in U \). Then we can write the expansion
\[
(e^U_\mu, e^U_a) = (D^\nu_\mu e_\mu + D^\nu_a e_a, D^b_\mu e_b) = (e_\nu, e_b) \cdot \begin{pmatrix} [D^\mu_a] & 0 \\ [D^\nu_\mu] & [D^b_\mu] \end{pmatrix},
\]
where \( \{e^U_I\} \) is a specialized frame in \( T(U) \), \( [D^\mu_a] \) and \( [D^b_\mu] \) are non-degenerate matrix-valued functions on \( U \), and \( D^\alpha_\mu : U \to \mathbb{K} \).

**Definition 3.3.** The specialized frame \( \{X_I\} \) over \( U \) in \( T(U) \), obtained from (3.18) via an admissible transformation (3.24) with matrix \( A = \begin{pmatrix} [D^\mu_a]^{-1} & 0 \\ 0 & [D^b_\mu]^{-1} \end{pmatrix} \), is called adapted to the frame \( \{e_I\} \) for \( \Delta^b \).

The frame \( \{X_I\} \) adapted to \( \{e_I\} \) is independent of the choice of the specialized frame \( \{e^U_I\} \) in (3.18) and can alternatively be defined by \( X_\mu = (\pi_*\Delta^b)^{-1} \circ \pi_* (e_\mu) \) and \( X_a = e_a \).

If \( \{u_I\} \) are bundle coordinates on \( U \), the frame \( \{X_I\} \) adapted to the coordinate frame \( \{\frac{\partial}{\partial u_I}\} \) is said to be adapted to the coordinates \( \{u_I\} \).

According to (3.21), the adapted frame \( \{X_I\} = \{X_\mu, X_a\} \) is given by the equation
\[
(X_\mu, X_a) = (e_\nu, e_b) \cdot \begin{pmatrix} \delta^\mu_\nu & 0 \\ \Gamma^b_\mu & \delta^b_a \end{pmatrix} = (e_\mu + \Gamma^b_\mu e_b, e_a)
\]
where the functions \( \Gamma^a_\mu : U \to \mathbb{K} \), called \( (2\text{-index}) \) coefficients of \( \Delta^h \) in \( \{X_I\} \), are defined by
\[
[\Gamma^a_\mu] := ([D^\mu_\nu] \cdot [D^\nu_\mu]^{-1}.
\]

A change \( \{e_I\} \rightarrow \{\tilde{e}_I\} \) with
\[
(e_\mu, \tilde{e}_a) = (e_\nu, e_b) \cdot \begin{pmatrix} [A^\mu_\nu] & 0 \\ [A^b_\mu] & [A^b_a] \end{pmatrix} = (A^\mu_\nu e_\nu + A^b_\mu e_b, A^b_a e_a),
\]
where \( [A^\mu_\nu] \) and \( [A^b_a] \) are non-degenerate matrix-valued functions on \( U \), which are constant on the fibres of \( (E, \pi, M) \), and \( A^b_\mu : U \to \mathbb{K} \), entails the transformations (see (3.18) (3.20))
\[
(X_\mu, X_a) \rightarrow (\tilde{X}_\mu, \tilde{X}_a) = (\tilde{e}_\mu + \tilde{\Gamma}^b_\mu \tilde{e}_b, \tilde{e}_a) = (A^\mu_\nu X_\nu, A^b_a X_b) = (X_\nu, X_b) \cdot \begin{pmatrix} A^\mu_\nu & 0 \\ 0 & A^b_a \end{pmatrix}
\]
\[
\Gamma^a_\mu \rightarrow \tilde{\Gamma}^a_\mu = ([A^\mu_\nu]^{-1})^a_b (\Gamma^b_\nu A^\mu_\nu - A^b_\mu)
\]
of the frame \( \{X_I\} \) adapted to \( \{e_I\} \) and of the coefficients \( \Gamma^a_\mu \) of \( \Delta^h \) in \( \{X_I\} \), i.e. \( \{\tilde{X}_I\} \) is the frame adapted to \( \{\tilde{e}_I\} \) and \( \tilde{\Gamma}^a_\mu \) are the coefficients of \( \Delta^h \) in \( \{\tilde{X}_I\} \).

**Note 3.1.** If \( \{e_I\} \) and \( \{\tilde{e}_I\} \) are adapted, then \( A^b_\mu = 0 \). If \( \{Y_I\} \) is a specialized frame, it is adapted to any frame \( \{e_\mu = A^\mu_\nu Y_\nu, e_a = A^b_a Y_b\} \) and hence any specialized frame can be considered as an adapted one; in particular, any specialized frame is a frame adapted to itself. Obviously, the coefficients of a connection identically vanish in a given specialized frame considered as an adapted one. This leads to the concept of a normal frame to which is devoted the present paper. Besides, from the above observation follows that the set of adapted frames coincides with the one of specialized frames.

\[\text{6} \] Recall, here and below the adapted frames are defined only with respect to frames \( \{e_I\} = \{e_\mu, e_a\} \) such that \( \{e_a\} \) is a basis for the vertical distribution \( \Delta^a \) over \( U \), i.e. \( \{e_a|_p\} \) is a basis for \( \Delta^a_p \) for all \( p \in U \). Since \( \Delta^a \) is integrable, the relation \( e_a \in \Delta^a \) for all \( a = n+1, \ldots, n+r \) implies \( [e_a, e_b]_* \in \Delta^a \) for all \( a, b = n+1, \ldots, n+r \).
In particular, if \( \{u^I\} \) and \( \{\tilde{u}^I\} \) are local bundle coordinates with non-empty intersection of their domains, we can set
\[
e^I = \frac{\partial}{\partial u^I}, \quad \tilde{e}^I = \frac{\partial}{\partial \tilde{u}^I},
\]
which entails
\[
A^\nu_\mu = \frac{\partial u^\nu}{\partial \tilde{u}^\mu} \quad A^b_a = \frac{\partial u^b}{\partial \tilde{u}^a}. \tag{3.25}
\]
So, when the holonomic choice \( \text{(3.30)} \) is made, the transformation \( \text{(3.28)} \) reduces to
\[
\Gamma^a_\mu \mapsto \tilde{\Gamma}^a_\mu = \left( \frac{\partial u^a}{\partial \tilde{u}^\mu} \Gamma^b_\nu + \frac{\partial u^a}{\partial u^\nu} \right) \frac{\partial u^\nu}{\partial \tilde{u}^\mu}. \tag{3.26}
\]

Let \( (E, \pi, M) \) be a vector bundle. According to the above-said in this section, any adapted frame \( \{X_I\} = \{X_\mu, X_a\} \) in \( T(E) \) is equivalent to a pair of frames in \( T(M) \) and \( E \) according to
\[
\{X_\mu, X_a\} \leftrightarrow \{(E_\mu = \pi_s|_{\Delta^h}(X_\mu), \{E_a = v^{-1}(X_a)\})\}. \tag{3.27}
\]

Suppose \( \{X_I\} \) and \( \{\tilde{X}_I\} \) are two adapted frames. Then they are connected by (cf. \( \text{(3.28)} \) and \( \text{(3.22)} \))
\[
\tilde{X}_\mu = (B^\nu_\mu \circ \pi)X_\nu \quad \tilde{X}_a = (B^b_a \circ \pi)X_b, \tag{3.28}
\]
where \( [B^\nu_\mu] \) and \( [B^b_a] \) as some non-degenerate matrix-valued functions on \( M \). The pairs of frames corresponding to them, in accordance with \( \text{(3.27)} \), are related via
\[
\tilde{E}_\mu = B^\nu_\mu E_\nu \quad \tilde{E}^a = B^b_a E_b \tag{3.29}
\]
and vice versa.

**Proposition 3.1.** Let \( \Delta^h \) be a linear connection on a vector bundle \( (E, \pi, M) \) \(^7\) and \( \{X_\mu\} \) be the frame adapted for \( \Delta^h \) to a frame \( \{e_I\} \) such that \( \{e_a\} \) is a basis for \( \Delta^u \) and
\[
(e_\mu, e_a)|_U = (\partial_\mu, \partial_b) \left[ \begin{array}{ccc} B^\nu_\mu \circ \pi & 0 \\ (B^b_a \circ \pi) \cdot E^c & B^b_a \circ \pi \end{array} \right] = \left( (B^\nu_\mu \circ \pi) \partial_\nu + ((B^b_c \circ \pi) \cdot E^c) \partial_b, (B^b_a \circ \pi) \partial_b \right), \tag{3.30}
\]
where \( \partial_\mu := \frac{\partial}{\partial u^\mu} \) for some local bundle coordinates \( \{u^I\} = \{u^\mu = x^\mu \circ \pi, u^b = E_b\} \) on \( U \subseteq E \), \( [B^\nu_\mu] \) and \( [B^b_a] \) are non-degenerate matrix-valued functions on \( U \), \( B^b_c: U \to \mathbb{K} \), and \( \{E^a\} \) is the coframe dual to \( \{E_a = v^{-1}(X_a)\} \). Then the 2-index coefficients \( \Gamma^a_\mu \) of \( \Delta^h \) in \( \{X_I\} \) have the representation
\[
\Gamma^a_\mu = -(\Gamma^a_\mu \circ \pi) \cdot E^b \tag{3.31}
\]
on \( U \) for some functions \( \Gamma^a_\mu: U \to \mathbb{K} \), called 3-index coefficients of \( \Delta^h \) in \( \{X_I\} \).

**Remark 3.1.** The representation \( \text{(3.31)} \) is not valid for frames more general than the ones given by \( \text{(3.30)} \). Precisely, equation \( \text{(3.31)} \) is valid if and only if \( \text{(3.30)} \) holds for some local coordinates \( \{u^I\} \) on \( U \) — see \( \text{(3.23)} \).

**Proof.** If \( e_I = \frac{\partial}{\partial u^I} \) for some local coordinates \( \{u^I\} \) on \( E \), the proposition coincides with the theorem in [18, p. 27]. Writing \( \text{(3.23)} \) for the transformation \( \{\partial_I\} \mapsto \{e_I\} \), with \( \{e_I\} \) given by \( \text{(3.30)} \), we get \( \text{(3.31)} \) with
\[
\Gamma^a_\mu = ((B^c_d)^{-1}c)(\partial \Gamma^c_\mu B^\nu_\mu + B^c_{b\mu}),
\]
where \( \partial \Gamma^c_\mu \) are the 3-index coefficients of \( \Delta^h \) in the frame adapted to the coordinates \( \{u^I\} \).

\(^7\) A connection on a vector bundle is linear if the generated by it parallel transport is a linear mapping [18].
Let \{X_I\} and \{\tilde{X}_I\} be frames adapted to \{e_I\} and \{\tilde{e}_I\}, respectively, with (cf. (3.30))

\[(\tilde{e}_\mu, \tilde{e}_a) = (e_\nu, e_b) \cdot \begin{bmatrix} B_\nu^\mu \circ \pi & 0 \\ (B_b^\mu \circ \pi) \cdot E^c & B_a^\nu \circ \pi \end{bmatrix}, \tag{3.32} \]
in which \(\Delta^h\) admits 3-index coefficients. Then, due to (3.23) and (3.31), the 3-index coefficients \(\Gamma_{b\mu}^a\) and \(\tilde{\Gamma}_{b\mu}^a\) of \(\Delta^h\) in respectively \{X_I\} and \{\tilde{X}_I\} are connected by

\[
\tilde{\Gamma}_{b\mu}^a = (B_f^c)^{-1} a_c (\Gamma_{d\nu}^a B_\mu^\nu + B_d^c B_b^d). \tag{3.33} 
\]

It can easily be checked that the transformation \{e_I\} \(\mapsto\) \{\tilde{e}_I\}, with \{\tilde{e}_I\} given by (3.32), is the most general one that preserves the existence of 3-index coefficients of \(\Delta^h\) provided they exist in \{e_I\}. Introducing the matrices \(\Gamma_\mu := [\Gamma_{b\mu b\nu}]_{a=0}^{n+1}, \tilde{\Gamma}_\mu := [\tilde{\Gamma}_{b\mu b\nu}]_{a=0}^{n+1}, B := [B_b]\), and \(B_\mu := [B_{b\mu}]\), we rewrite (3.33) as

\[
\tilde{\Gamma}_\mu = B^{-1} \cdot (\Gamma_\nu B_\nu^{\mu} + B_\mu) \cdot B. \tag{3.33} 
\]

A little below (see the text after equation (3.35)), we shall prove that the compatibility of the developed formalism with the theory of covariant derivatives requires further restrictions on the general transformed frames (3.24) to the ones given by (3.32) with

\[
B_\mu = \tilde{E}_\mu(B) \cdot B^{-1} = B_\mu^{\nu} E_\nu(B) \cdot B^{-1}, \tag{3.34} 
\]

where \(\tilde{E}_\mu := \pi_\mu |_{\Delta^h}(\tilde{X}_\mu) = \pi_\mu |_{\Delta^h}(B_\mu^{\nu} \circ \pi)X_\nu = B_\mu^{\nu} E_\nu\). In this case, (3.33) reduces to

\[
\tilde{\Gamma}_\mu = B_\mu^{\nu} B^{-1} \cdot (\Gamma_\nu \cdot B + E_\nu(B)) = B_\mu^{\nu} (B^{-1} \cdot \Gamma_\nu - E_\nu(B^{-1})) \cdot B. \tag{3.35} 
\]

At last, a few words on the covariant derivatives operators \(\nabla\) are in order. Without lost of generality, we define such an operator

\[
\nabla : \mathcal{X}(M) \times \text{Sec}^1(E, \pi, M) \rightarrow \text{Sec}^0(E, \pi, M) \tag{3.36} 
\]

\[
\nabla : (F, Y) \mapsto \nabla F Y
\]

via the equations

\[
\nabla_{F+G} Y = \nabla_F Y + \nabla_G Y \tag{3.37a} 
\]

\[
\nabla_{fF} Y = f \nabla F Y \tag{3.37b} 
\]

\[
\nabla_F(Y + Z) = \nabla_F Y + \nabla_F Z \tag{3.37c} 
\]

\[
\nabla_F(fY) = F(f) \cdot Y + f \cdot \nabla F Y, \tag{3.37d} 
\]

where \(F, G \in \mathcal{X}(M), Y, Z \in \text{Sec}^1(E, \pi, M),\) and \(f : M \rightarrow \mathbb{K}\) is a \(C^1\) function. Suppose \{\(E_\mu\)\} is a basis for \(\mathcal{X}(M)\) and \{\(E_a\)\} is a one for \(\text{Sec}^1(E, \pi, M)\). Define the components \(\Gamma_{b\mu}^a : M \rightarrow \mathbb{K}\) of \(\nabla\) in the pair of frames \((\{E_\mu\}, \{E_a\})\) by

\[
\nabla_{E_\mu}(E_b) = \Gamma_{b\mu}^a E_a. \tag{3.38} 
\]

Then (3.37) imply

\[
\nabla_F Y = F^\mu(E_\mu(Y^a) + \Gamma_{b\mu}^a Y^b)E_a 
\]

for \(F = F^\mu E_\mu \in \mathcal{X}(M)\) and \(Y = Y^a E_a \in \text{Sec}^1(E, \pi, M)\). A change \((\{E_\mu\}, \{E_a\}) \mapsto (\{\tilde{E}_\mu\}, \{\tilde{E}_a\})\), given via (3.29), entails

\[
\Gamma_{b\mu}^a \mapsto \tilde{\Gamma}_{b\mu}^a = B_\mu^{\nu} ([B_f^c]^{-1}) a_c (\Gamma_{d\nu}^c B_d^d + E_\nu(B_f^c)). \tag{3.39} 
\]
as a result of \(3.38\). In a more compact matrix form, the last result reads
\[
\hat{\Gamma}_\mu = B'^\nu B^{-1} \cdot (\Gamma_\nu \cdot B + E_\nu(B)) \tag{3.39}
\]
with \(\Gamma_\mu := [\Gamma^a_{\mu b}], \hat{\Gamma}_\mu := [\hat{\Gamma}^a_{b\nu}],\) and \(B := [B^a_b]\).

Thus, if we identify the 3-index coefficients of \(\Delta^h\), defined by \(3.34\), with the components of \(\nabla\), defined by \(3.38\) \(8\), then the quantities \(3.38\) \(8\) and \(3.39\) must coincide, which immediately leads to the equality \(3.39\). Therefore
\[
(e_\mu, e_a) \mapsto (\hat{e}_\mu, \hat{e}_a) = (e_\nu, e_b) \cdot \begin{bmatrix}
B'_\mu \circ \pi & 0 \\
((B'_\mu E_\nu(B^b_d)(B^{-1})^c_d \circ \pi)E^c & B'^b_a \circ \pi \end{bmatrix} \bigg|_{B=[B^a_b]} \tag{3.40}
\]
is the most general transformation between frames in \(T(E)\) such that the frames adapted to them are compatible with the linear connection and the covariant derivative corresponding to it. In particular, such are all frames \(\{\frac{\partial}{\partial u^I}\}\) in \(T(E)\) induced by some vector bundle coordinates \(\{u^I\}\) on \(E\) as the vector fibre coordinates transform in a linear way like \(v^I \mapsto \hat{v}^I = (B^a_b \circ \pi) \cdot u^b\); the rest members of the class of frames mentioned are obtained from them via \(3.40\) with \(e_I = \frac{\partial}{\partial u^I}\) and some non-degenerate matrix-valued functions \(B^a_b\) and \(B\).

If \(\{X_I\}\) (resp. \(\{\hat{X}_I\}\)) is the frame adapted to a frame \(\{e_I\}\) (resp. \(\{\hat{e}_I\}\)), then the change \(\{e_I\} \mapsto \{\hat{e}_I\}\), given by \(3.40\), entails \(\{X_I\} \mapsto \{\hat{X}_I\}\) with \(\{\hat{X}_I\}\) given by \(3.28\) (see \(3.21\) and \(3.22\)). Since the last transformation is tantamount to the change
\[
(\{E_\mu\}, \{E_a\}) \mapsto (\{\hat{E}_\mu\}, \{\hat{E}_a\}) \tag{3.41}
\]
of the basis of \(\mathcal{X}(M) \times \text{Sec}(E, \pi, M)\) corresponding to \(\{X_I\}\) via \(3.27\), \(3.28\), and \(3.29\), we can say that the transition \(3.41\) induces the change \(3.39\) of the 3-index coefficients of the connection \(\Delta^h\). Exactly the same is the situation one meets in the literature \([13,14,19]\) when covariant derivatives are considered (and identified with connections).

Regardless that the change \(3.40\) of the frames in \(T(E)\) looks quite special, it is the most general one that, through \(3.22\) and \(3.27\), is equivalent to an arbitrary change \(3.41\) of a basis in \(\mathcal{X}(M) \times \text{Sec}(E, \pi, M)\), i.e. of a pair of frames in \(T(M)\) and \(E\).

4. Normal frames: general case

In the theory of linear connections on a manifold, the normal frames are defined as frames in the tangent bundle space in which the connections’ (3-index) coefficients vanish on some subset of the manifold \([6–9,14,19]\). The definition of normal frames for a connection on a vector bundle is practically the same, the only difference being that these frames are in the bundle space, not in the tangent bundle space over the base space \([10]\). The present section is devoted to the introduction of normal frames for general connections on fibre bundles and some their properties.

To save some space and for brevity, in what follows we shall not indicate explicitly that the frames \(\{e_I\} = \{e_\mu, e_a\}\), with respect to which the adapted frames are defined, are such that \(\{e_a\}\) is a (local) basis for the vertical distribution \(\Delta^v\) on the bundle considered.

**Definition 4.1.** Given a connection \(\Delta^h\) on a bundle \((E, \pi, M)\) and a subset \(U \subseteq E\). A frame \(\{X_I\}\) in \(T(E)\) adapted to a frame \(\{e_I\}\) in \(T(E)\) and defined over an open subset \(V\) of \(E\) containing or equal to \(U\), \(V \supseteq U\), is called normal for \(\Delta^h\) over/on \(U\) (relative to \(\{e_I\}\)) if in it all (2-index) coefficients \(\Gamma^a_{\mu b}\) of \(\Delta^h\) vanish everywhere on \(U\). Respectively, \(\{X_I\}\) is normal for \(\Delta^h\) along a mapping \(g\): \(Q \to E\), \(Q \neq \emptyset\), if \(\{X_I\}\) is normal for \(\Delta^h\) over the set \(g(Q)\).

\(8\) Such an identification is justified by the definition of \(\nabla\) via the parallel transport assigned to \(\Delta^h\) or via a projection, generated by \(\Delta^h\), of a suitable Lie derivative on \(\mathcal{X}(E)\) — see \([18]\).
Let \( \{X_I\} \) be the frame in \( T(E) \) adapted to a frame \( \{e_I\} \) in \( T(E) \) over an open subset \( V \subset E \). Then the frame \( \{\tilde{X}_I\} \) in \( T(E) \) adapted to a frame \( \{\tilde{e}_I\} \), given by (3.21), in \( T(E) \) over the same subset \( V \) is normal for \( \Delta^h \) over \( U \subset V \) if and only if

\[
(A^b_\mu \Gamma^b_\nu - A^b_\mu)_{|U} = 0,
\]

(4.1)
due to (3.22) and (3.23). Since \( \Gamma^b_\mu \) depend only on \( \Delta^h \) and \( \{e_I\} \), the existence of solutions of (4.1), relative to \( A^\nu_\mu \) and \( A^b_\mu \), and their properties are completely responsible for the existence and the properties of frames normal for \( \Delta^h \) over \( U \). For that reason, we call (4.1) the (system of) equation(s) of the normal frames for \( \Delta^h \) over \( U \) or simply the normal frame (system of) equation(s) (for \( \Delta^h \) over \( U \)).

In the most general case, when no additional restrictions on the frames considered are imposed, the normal frames equation (4.1) is a system of \( nr \) linear algebraic equations for \( nr + n^2 \) variables and, consequently, it has a solution depending on \( n^2 \) independent parameters. In particular, if we choose the functions \( A^\nu_\mu : U \to \mathbb{K} \) (with \( \det[A^\nu_\mu] \neq 0, \infty \)) as such parameters, we can write the general solution of (4.1) as

\[
(|A^\nu_\mu, \{A^b_\mu\}|_U = (\{A^\nu_\mu, \{\Gamma^b_\mu A^a_\nu\}|_U. \quad (4.2)
\]

It should be noted, equation (4.1) or its general solution (4.2) defines the frame \( \{\tilde{e}_I\} \) and the frame \( \{\tilde{X}_I\} \) adapted to \( \{\tilde{e}_I\} \) only on \( U \) and leaves them completely arbitrary on \( V \setminus U \), if it is not empty.

**Proposition 4.1.** Let \( \{X_I\} \) be the frame adapted to a frame \( \{e_I\} \) in \( T(V) \subset T(E) \) defined over an open set \( V \subset E \) and \( \Gamma^a_\mu \) be the coefficients of a connection \( \Delta^h \) in \( \{X_I\} \). Then all frames \( \{\tilde{X}_I\} \) normal on \( U \subset V \) for the connection \( \Delta^h \) are adapted to frames \( \{\tilde{e}_I\} \) given on \( U \) by

\[
\tilde{e}_\mu|_U = (A^\nu_\mu(e_\nu + \Gamma^a_\mu e_a)|_U \quad \tilde{e}_a|_U = (A^b_\mu e_b)|_U.
\]

(4.3)

where \( [A^\nu_\mu] \) and \( [A^b_\mu] \) are non-degenerate matrix-valued functions on \( V \) which are constant on the fibres of \( (E, \pi, M) \). Moreover, the frame \( \{\tilde{X}_I\} \) adapted on \( V \) to \( \{\tilde{e}_I\} \), given by (4.3) (and hence normal on \( U \)), is such that

\[
\tilde{X}_\mu|_U = (A^\nu_\mu X_\nu)|_U = \tilde{e}_\mu|_U \quad \tilde{X}_a|_U = (A^b_\mu X_b)|_U = \tilde{e}_a|_U.
\]

(4.4)

**Proof.** Apply (3.22), (3.21), and (3.19) for the choice (4.2).

The equations (4.4) are not accidental as it is stated by the following assertion.

**Proposition 4.2.** The frame \( \{\tilde{X}_I\} \) in \( T(E) \) adapted to a frame \( \{\tilde{e}_I\} \) in \( T(E) \) and defined over an open set \( V \subset E \) is normal on \( U \subset V \) if and only if on \( U \) is fulfilled

\[
\tilde{X}_I|_U = \tilde{e}_I|_U.
\]

(4.5)

**Proof.** Apply (3.19) or (3.22) and definition (4.1)

Thus one can equivalently define the normal frames as adapted frames that coincide on some set with the frames they are adapted to or as frames (in the tangent bundles space over the bundle space) that coincide on some set with the frames adapted to them.

Since any specialized frame is adapted to itself (see definition (3.3) and (3.18), with \( D^I_I = \delta^I_I \)), the sets of normal, specialized, and adapted frames are identical.

As we see from proposition (4.1) which gives a complete description of the normal frames, the theory of normal frames in the most general setting is trivial. It becomes more interesting and richer if the class of frames \( \{e_I\} \), with respect to which are defined the adapted frames, is restricted in one or other way. To the theory of normal frames, adapted to such restricted classes of frames in \( T(E) \), are devoted the next two sections.
5. Normal frames adapted to holonomic frames

The most natural class of frames in $T(E)$ relative to which the adapted, in particular normal, frames are defined is the one of holonomic frames induced by local coordinates on $E$ (see Subsect. 3.2). To specify the consideration of the previous section to normal frames adapted to local coordinates on $E$, we set $e_I = \frac{\partial}{\partial q^a}$ and $\tilde{e}_I = \frac{\partial}{\partial \tilde{u}^a}$, where $\{u^I\}$ and $\{\tilde{u}^I\}$ are local coordinates on $E$ whose domains have a non-empty intersection $V$ and $U \subseteq V$. Then the matrix $[A_I^J]$ in (4.1) is given by (3.3) (as $\{e_I\} \mapsto \{\tilde{e}_I\}$ reduces to (3.2)), so that the normal frame equation (1.1) reduces to the normal coordinates equation (see also (5.2))

$$\left(\frac{\partial \tilde{u}^a}{\partial u^b} \Gamma^b_\mu + \frac{\partial \tilde{u}^a}{\partial u^\mu}\right)_{|U} = 0,$$

(5.1)
due to (3.1), which is a first order system of $nr$ linear partial differential equations on $U$ relative to the $r$ unknown functions $\{\tilde{u}^{n+1}, \ldots, \tilde{u}^{n+r}\}$.

Since the connection $\Delta^h$ is supposed given and fixed, such are its coefficients $\Gamma^b_\mu$ in $\{\frac{\partial}{\partial u^\mu}\}$. Therefore the existence, uniqueness and other properties of the solutions of (5.1) strongly depend on the set $U$ (which is in the intersection of the domains of the local coordinates $\{u^I\}$ and $\{\tilde{u}^I\}$ on $E$).

**Proposition 5.1.** If the normal frame equation (5.1) has solutions, then all frames $\{\tilde{X}_I\}$ normal on $U \subseteq E$ and adapted to local coordinates, defined on an open set $V \subseteq E$ such that $V \supseteq U$, are described by

$$\tilde{X}_\mu|_U = (A^\nu_\mu X_\nu)|_U = \frac{\partial}{\partial \tilde{u}^\mu}|_U \quad \tilde{X}_a|_U = (A^b_a X_b)|_U = \frac{\partial}{\partial u^a}|_U,$$

(5.2)

where $\{X_\nu\}$ is the frame adapted to some arbitrarily fixed local coordinates $\{u^I\}$, defined on an open set containing or equal to $V$, $\{\tilde{u}^I\}$ are local coordinates with domain $V$ and such that $\tilde{u}^a$ are solutions of (5.1), and $A^I_a = \frac{\partial \tilde{u}^I}{\partial u^a}$ on the intersection of the domains of $\{u^I\}$ and $\{\tilde{u}^I\}$.

**Proof.** Apply proposition (1.1) for $e_I = \frac{\partial}{\partial q^a}$ and $\tilde{e}_I = \frac{\partial}{\partial \tilde{u}^a}$ and then use (3.2) and (3.3). □

This simple result gives a complete description of all normal frames, if any, adapted to (local) holonomic frames. It should be understood clearly, normal on $U$ is the frame $\{\tilde{X}_I\}$, adapted to $\{\frac{\partial}{\partial u^a}\}$ and coinciding with it on $U$, but not the frame $\{\frac{\partial}{\partial \tilde{u}^a}\}$; in particular, the frame $\{\frac{\partial}{\partial u^a}\}$ is holonomic while the frame $\{\tilde{X}_I\}$ need not to be holonomic, even on $U$, if the connection considered does not satisfy some additional conditions, like the vanishment of its curvature on $U$.

Consider now briefly the existence problem for the solutions of (5.1). To begin with, we emphasize that in (5.1) enter only the fibre coordinates $\{\tilde{u}^a\}$, so that it leaves the basic ones $\{\tilde{u}^\mu\}$ completely arbitrary.

**Proposition 5.2.** If $E$ is of class $C^2$, $p \in E$ is fixed, and $U = \{p\}$, then the general solution of (5.1) is

$$\tilde{u}^a(q) = g^a + g^a_b \{- \Gamma^b_\mu(p)(q^\mu - p^\mu) + (q^b - p^b)\} + f^a_f(q)(q^f - p^f)(q^f - p^f),$$

(5.3)

where $g^a$ and $g^a_b$ are constants in $\mathbb{K} = \mathbb{R}, \mathbb{C}$, $\det[g^a_b] \neq 0, \infty$, the point $q$ is in the domain $V$ of $\{u^I\}$, $q^f := u^f(p)$, and $f^a_f$ are $C^2$ functions on $V$ such that they and their first partial derivatives are bounded when $q^f \to p^f$.

**Proof.** Expand $\tilde{u}^a(q) = f^a(u^1(q), \ldots, u^n(q)) \ldots u^{n+r}(q)) = f^a(q^1, \ldots, q^{n+r})$ into a Taylor’s first order polynomial with remainder term quadratic in $(q^f - p^f)$ and insert the result into (5.1). In this way, we get (5.3) with $g^a = \tilde{u}^a(p)$ and $g^a_b = \frac{\partial \tilde{u}^a}{\partial u^b}|_p$. □
Now we would like to investigate the existence of solutions of (5.1) along paths \( \beta : J \rightarrow E \), i.e. for \( U = \beta(J) \). The main result is formulated below as proposition 5.3. For its proof, we shall need the following lemma.

**Lemma 5.1.** Let \( \gamma : J \rightarrow M \) be a regular \( C^1 \) injective path in a \( C^3 \) real manifold \( M \). For every \( s_0 \in J \), there exists a chart \((U_1, x)\) of \( M \) such that \( \gamma(s_0) \in U_1 \) and \( x(\gamma(s)) = (s, t_0) \) for all \( s \in J \) such that \( \gamma(s) \in U_1 \) and some fixed \( t_0 \in \mathbb{R}^{\dim M - 1} \).

**Proof.** Let \( s_0 \in J \) be a point in \( J \) which is not an end point of \( J \), if any, and \((U, y)\) be a chart with \( \gamma(s_0) \) in its domain, \( U \ni \gamma(s_0) \), and \( y : U \rightarrow \mathbb{R}^{\dim M} \). From the regularity of \( \gamma \), \( \dot{\gamma} \neq 0 \), follows that at least one of the numbers \( \gamma_j^y(s_0), \ldots, \gamma_j^y(\dim M) \), where \( \gamma^y := y \circ \gamma \), is non-zero. We, without loss of generality, choose this non-vanishing component to be \( \gamma_j^y(s_0) \).

Then, due to the continuity of \( \dot{\gamma} \) (\( \dot{\gamma} \) is of class \( C^1 \)) and according to the implicit function theorem [20, chapter III, § 8], [13, sect. 1.37 and 1.38], [21, chapter 10, sect. 2], there exists an open subinterval \( J_1 \subseteq J \) containing \( s_0 \), \( J_1 \supseteq s_0 \), and such that \( \dot{\gamma}_j^y|_{J_1} \neq 0 \) and the restricted mapping \( \dot{\gamma}_j^y|_{J_1} : J_1 \rightarrow \gamma_j^y(J_1) \) is a \( C^1 \) diffeomorphism on its image. Define a neighborhood

\[
U_1 := \{ p \in U, \ y^1(p) \in \gamma_j^y(J_1) \} = \gamma^{-1}(\gamma_j^y(J_1) \times \mathbb{R}^{\dim M - 1}) \ni \gamma(s_0)
\]

and a chart \((U_1, x)\) with local coordinate functions

\[
x^1 := (\gamma_j^y|_{J_1})^{-1} \circ y^1
\]

\[
x^k := y^k - \gamma_j^y \circ x^1 + t_0^k \quad k = 2, \ldots, \dim \mathbb{R}^M
\]

where \( t_0^k \in \mathbb{R} \) are constant numbers. Since \( \frac{\partial x^1}{\partial y^j} = \frac{1}{\gamma_j^y} \beta^1 \), \( \frac{\partial x^k}{\partial y^j} = \frac{-\gamma_j^y}{\gamma_j^y} \), for \( k \geq 2 \), and \( \frac{\partial x^k}{\partial y^j} = \delta_j^k \) for \( k, l \geq 2 \), the Jacobian of the change \( \{y^i\} \rightarrow \{x^j\} \) at \( p \in U_1 \) is \( \frac{1}{\gamma_j^y(p)} \neq 0, \infty \). Consequently \( \{x^i\} : U_1 \rightarrow J_1 \times \mathbb{R}^{\dim M - 1} \) is really a coordinate homeomorphism with coordinate functions \( x^j \).

In the new chart \((U_1, x)\), the coordinates of \( \gamma(s) \), \( s \in J_1 \) are

\[
\gamma^j(s) := (x^1 \circ \gamma)(s) = s, \quad \gamma^k(s) := (x^k \circ \gamma)(s) = t_0^k, \quad k \geq 2,
\]

i.e. \( x(\gamma(s)) = (s, t_0) \) for some \( t_0 = (t_0^2, \ldots, t_0^{\dim M}) \in \mathbb{R}^{\dim M - 1} \).

**Lemma 5.1** means that the chart \((U_1, x)\) is so luckily chosen that the first coordinate in it is of a point along \( \gamma \) coincides with the value of the corresponding path’s parameter, the other coordinates being constant numbers. Moreover, in \( U_1 \) the path \( \gamma \) can be considered as a representative of a family of paths \( \eta(s, t) : J_1 \rightarrow M, \ t \in \mathbb{R}^{\dim M - 1} \), defined by \( \eta(s, t) := x^{-1}(s, t) \) for \( (s, t) \in J_1 \times \mathbb{R}^{\dim M - 1} \); indeed, \( \gamma = \eta(s, t_0) \) or \( \gamma(s) = \eta(s, t_0) \), \( s \in J_1 \subseteq J \).

**Proposition 5.3.** Let \( \Delta^h \) be a \( C^1 \) connection on a real \( C^3 \) bundle \((E, \pi, M)\), \( n = \dim M \geq 1 \), \( r = \dim \pi^{-1}(x) \geq 1 \) for \( x \in M \). Let \( \beta : J \rightarrow E \) be an injective regular \( C^1 \) path such that its tangent vector \( \dot{\beta}(s) \) at \( s \) is not a vertical vector for all \( s \in J \), \( \beta(s) \notin \Delta^v_{\beta(s)} \); in particular, the path \( \beta \) can be horizontal, i.e. \( \dot{\beta}(s) \in \Delta^h_{\beta(s)} \) for all \( s \in J \), but generally the vector \( \dot{\beta}(s) \) can have also and a vertical component for some or all \( s \in J \). Then, for every \( s_0 \in J \), there exist a neighborhood \( U_1 \) of the point \( \beta(s_0) \) in \( E \) and bundle coordinates \( \{u^j\} \) on \( U_1 \) which are solutions of (5.1) for \( U = U_1 \cap \beta(J) = \beta(J_1) \), with \( J_1 := \{ s \in J : \beta(s) \in U_1 \} \), i.e. along the restricted path \( \beta|_{J_1} \). All such bundle coordinates \( \{u^j\} \) are given via the equation (5.6) below.

---

9If it happens that \( \gamma^1_j(s_0) = 0 \) and \( \gamma^1_j(s_0) \neq 0 \) for some \( i_0 \neq 1 \), we have simply to renumber the local coordinates to get \( \gamma^1_j(s_0) \neq 0 \). Practically this is a transition to new coordinates \( \{y'\} \rightarrow \{z'\} \) with \( z^1 = y^{i_0} \) and, for instance, \( z^0 = y' \) and \( z^i = y'^i \) for \( i \neq 1, i_0 \), in which the first component of \( \gamma \) is non-zero. We suppose that, if required, this coordinate change is already done. If occasionally it happens that \( \gamma^1_j(s) \neq 0 \) for all \( s \in J \) and fixed \( j_0 \), it is extremely convenient to take this particular component of \( \gamma \) as \( \gamma^1_j \) — see the next sentence.
Proof. Consider the chart \((U_1, u)\) with \(U_1 \ni \beta(s_0)\) provided by lemma 5.1 for \(E\) and \(\beta\) instead of \(M\) and \(\gamma\), respectively. For any \(p \in U_1\), there is a unique \((s, t) \in J_1 \times \mathbb{R}^\text{dim}_E\) such that \(p = u^{-1}(s, t)\), i.e., in the coordinates \(\{u^I\}\) associated to \(u\), the coordinates of \(p\) are \(u^I(p) = s\) and \(u^I(p) = t^I \in \mathbb{R}\) for \(I \geq 2\). Besides, we have \(\beta(s) = (s, t_0)\) for all \(s \in J_1\) and some fixed \(t_0 \in \mathbb{R}^\text{dim}_E\).

Since \(\dot{\beta}(s)\) is not a vertical vector for all \(s \in J\), the coordinates \(\{u^I\}\) can be chosen to be bundle coordinates. For the purpose, in the proof of lemma 5.1 one must choose \(\{y^I\}\) as bundle coordinates and to take for \(\beta^I(s_0)\) any non-vanishing component between \(\beta^1_y(s_0), \ldots, \beta^y_y(s_0)\), viz. if \(\beta^1_y(s_0) \neq 0\) the proof goes as it is written and, if \(\beta^1_y(s_0) = 0\), choose some \(\mu_0\) such that \(\beta^1_y(s_0) \neq 0\) and make, e.g., the change \(\beta^1_y(s_0) \leftrightarrow \beta^\mu_y(s_0)\). This, together with 5.4, with \(u^I\) for \(x^k\), ensures that \(\{y^I\} \mapsto \{u^I\}\) is an admissible change, so that \(\{u^I\}\) are bundle coordinates if the initial coordinates \(\{y^I\}\) are such ones.

Let \(\{u^I\}\) be so constructed bundle coordinates and \(\eta := u^{-1}\), so that \(\beta(s) = \eta(s, t_0)\). Expanding \(\tilde{u}^\alpha(\eta(s, t))\) into a first order Taylor's polynomial at the point \(t_0 \in K\), we find the general solution of (5.1), with \(U = \beta(J_1) = U_1 \cap \beta(J)\), in the form

\[
\tilde{u}^\alpha(\eta(s, t)) = B^\alpha(s) + B^\alpha_b(s)\{-\Gamma^b_{\mu}(\beta(s))[u^\mu(\eta(s, t)) - \mu^\mu(\beta(s))] + [u^b(\eta(s, t)) - \mu^b(\beta(s))]\}
\]

where \(B^a, B^a_b : J_1 \rightarrow \mathbb{R} = \mathbb{R}, \det[B^a] \neq 0, \infty, \) and the C^1 functions \(B^a_I\) and their first partial derivatives are bounded when \(t \rightarrow t_0\). (Notice, the terms with \(\mu = 1\) and/or \(I = 1\) and/or \(J = 1\) do not contribute in (5.6) as \(u^1(\eta(s, t)) \equiv s\) and, besides, the functions \(B^a_I\) can be taken symmetric in \(I\) and \(J\), \(B^a_I\) = \(B^a_J\).)

Remark 5.1. If there is \(s_0 \in J\) for which \(\dot{\beta}(s_0)\) is a vertical vector, \(\dot{\beta}(s_0) \in \Delta_{\beta(s_0)}\), then proposition 5.3 remains true with the only correction that the coordinates \(\{u^I\}\) will not be bundle coordinates. If this is the case, the constructed coordinates \(\{\tilde{u}^I\}\) will be solutions of 5.1, but we cannot assert that they are bundle coordinates which are (locally) normal along \(\beta\) in a neighborhood of the point \(\beta(s_0)\).

Proposition 5.3 can be generalized by requiring \(\beta\) to be locally injective instead of injective, i.e. for each \(s \in J\) to exist a subinterval \(J_S \subseteq J\) such that \(J_S \ni s\) and the restricted path \(\beta|_{J_S}\) to be injective. Besides, if one needs a version of the above results for complex bundles, they should be considered as real ones (with doubled dimension of the manifolds) for which are applicable the above considerations.

Corollary 5.1. At any arbitrarily fixed point in \(E\) and/or along a given injective regular C^1 path in \(E\), whose tangent vector is not vertical, there exist (possibly local, in the latter case) normal frames.

Proof. See definition 5.1, propositions 5.2 and 5.3, and equation (5.1). If the path is not contained in a single coordinate neighborhood, one should cover its image in the bundle space with such neighborhoods and, then, to apply proposition 5.3 in the intersection of the coordinate domains, the uniqueness (and, possibly, continuity or differentiability) of the normal frames may be lost.

Definition 5.1. Local bundle coordinates \(\{\tilde{u}^I\}\), defined on an open set \(V \subseteq E\), will be called normal on \(U \subseteq V\) for a connection \(\Delta^h\) if the frame \(\{\tilde{X}_I\}\) in \(T(E)\) adapted to \(\{\frac{\partial}{\partial \tilde{u}^I}\}\) over \(V\) is normal for \(\Delta^h\) on \(U\).

Corollary 5.1 implies the existence of coordinates normal at a given point or (locally) along a given injective path whose tangent vector is not vertical; in particular, there exist
coordinates normal along an injective horizontal path. However, normal coordinates generally do not exist on more general subsets of the bundle space $E$. A criterion for existence of coordinates normal on sufficiently general subsets $U \subseteq E$, e.g. on ‘horizontal’ submanifolds, is given by theorem A.1 in the Appendix. In particular, we have the following corollary from this theorem.

**Proposition 5.4.** If $\Delta^h$ is a $C^1$ connection, $U$ is an open set in $E$, and normal frames for $\Delta^h$ on $U$ exist, then there are holonomic such frames if $\Delta^h$ is flat on $U$. Said otherwise, the system of equations (5.1) may admit solutions on an open set $U$ if

$$R^a_{\mu\nu}|_U = 0$$

where

$$R^a_{\mu\nu} = \partial_\mu(\Gamma^a_\nu) - \partial_\nu(\Gamma^a_\mu) + \Gamma^b_\mu \partial_b(\Gamma^a_\nu) - \Gamma^b_\nu \partial_b(\Gamma^a_\mu) = X_\mu(\Gamma^a_\nu) - X_\nu(\Gamma^a_\mu).$$

are the (fibre) components of the curvature of $\Delta^h$ in some frame $\{X^I\}$ on $E$ adapted to a holonomic one (see also [18]).

**Remark 5.2.** However, in the general case the flatness of a connection on an open set is only a necessary, but not sufficient, condition for the existence of coordinates normal on that set — see theorem A.1 in the Appendix. Exceptions are the linear connections on vector bundles — see remark A.3 in the Appendix. One can easily show that part of the integrability conditions for (5.1) for an open set $U$ are

$$0 = \frac{\partial^2 \tilde{u}^a}{\partial u^\nu \partial u^\mu} - \frac{\partial^2 \tilde{v}^a}{\partial u^\mu \partial u^\nu} = \frac{\partial \tilde{u}^a}{\partial u^b} R^b_{\mu\nu}$$

from where proposition 5.4 immediately follows. However, the flatness of the connection on $U$ generally does not imply the rest of the integrability conditions, viz. $\frac{\partial^2 \tilde{u}^a}{\partial u^\nu \partial u^\mu} - \frac{\partial^2 \tilde{v}^a}{\partial u^\mu \partial u^\nu} = 0$ and $\frac{\partial^2 \tilde{u}^a}{\partial u^\nu \partial v^\mu} - \frac{\partial^2 \tilde{v}^a}{\partial u^\mu \partial v^\nu} = 0$.

The combination of propositions 5.4 and 4.2 implies the non-existence of coordinates normal on an open set for non-flat (non-integrable) connections.

### 6. Normal frames on vector bundles

The normal frames for covariant derivative operators (linear connections), other derivations, and linear transports along paths are known and studied objects in vector bundles [10, 11]. The goal of the present section is to be made a link between them and the general theory of Sect. 4.

Consider a linear connection $\Delta^h$ on a vector bundle $(E, \pi, M)$, i.e. a connection the assigned to which parallel transport is a linear mapping. Let the frame $\{e_I\}$ in $T(E)$ be given by (3.30) and $\{X_I\}$ be the frame adapted to $\{e_I\}$ for $\Delta^h$. Then, by proposition 3.1 the 2- and 3-index coefficients of $\Delta^h$ are connected via (3.31) in which $\{E^a\}$ is a frame over $M$ dual to the frame $\{E_a = v^{-1}(X_a)\}$ in $E$, with $v$ defined by (3.14).

**Proposition 6.1.** A frame $\{X_I\}$ is normal on $U \subseteq E$ for a linear connection $\Delta^h$ if and only if it vanish the 3-index coefficients of $\Delta^h$ on $\pi(U) \subseteq M$,

$$\Gamma^a_\mu|_U = 0 \iff \Gamma^a_{\mu\nu}|_{\pi(U)} = 0.$$
Proof. Since the linear forms $E^{n+1}|_p, \ldots, E^{n+r}|_p$ are linearly independent for all $p \in U$, the assertion follows from equation (3.31).

Combining proposition 6.1 with (6.33), we see that the normal frame equation (4.1) in vector bundle is equivalent to

$$B^\nu \Gamma_\mu^a \mathbb{b} + B^a_{\mathbb{b} \mu})_{\mathbb{p}(U)} = 0 \tag{6.2}$$

or to its matrix variant (see also (6.33)); $\Gamma_\nu := [\Gamma^0_{\mu \nu}], B_\mu := [B^a_{\mathbb{b} \mu}]$

$$B^\nu \Gamma_\nu + B_\mu)_{\mathbb{p}(U)} = 0. \tag{6.2}$$

Taking into account (6.2) and (6.32), we can assert that the frame $\{\tilde{X}_I\}$ adapted to the frame

$$(\tilde{e}_\mu, \tilde{e}_a) = (e_\nu, e_b) \cdot \begin{bmatrix} B^\nu_\mu \circ \pi & 0 \\ -((B^a_\mu \Gamma_\mu^b \circ \pi) \cdot E^c \mathbb{b} B^b_\nu \circ \pi) & \end{bmatrix}, \tag{6.3}$$

where $[B^\nu_\mu]$ and $[B^a_\nu]$ are non-degenerate matrix-valued functions, is normal on $U$ for $\Delta^h$ and hence $\tilde{X}_I = \tilde{e}_I$, by virtue of proposition 4.2. Recall (see (3.21), (3.22), and (6.20)), the change $\{e_I\} \mapsto \{\tilde{e}_I\}$, given by (6.3), entails $\{X_I\} \mapsto \{\tilde{X}_I\}$, where

$$\tilde{X}_\mu = (B^\nu_\mu \circ \pi) X_\nu \quad \tilde{X}_a = (B^b_\mu \circ \pi) X_b, \tag{6.4}$$

which is equivalent to $\{E_I\} \mapsto \{\tilde{E}_I\}$ with

$$\tilde{E}_\mu = B^\nu_\mu E_\nu \quad \tilde{E}_a = B^b_\nu E_b. \tag{6.5}$$

Here (see (3.21)) $\{E_\mu = \pi_*|_{\Delta^h}(X_\mu)\}$ is a frame in $T(M)$ and $\{E_a = V^{-1}(X_a)\}$ is a frame in $E$.

Thus, if additional restriction are not imposed, the theory of normal frames in vector bundles is rather trivial, which reflects a similar situation in general bundles, considered in Sect. 4. However, the really interesting and sensible case is when one considers frames compatible with the covariant derivatives. As we know (see (3.31)), it corresponds to arbitrary non-degenerate matrix-valued functions $[B^\nu_\mu]$ and $B = [B^a_\nu]$ and a matrix-valued functions $B_\mu = [B^a_{\mathbb{b} \mu}]$ given by

$$B_\mu = \tilde{E}_\mu (B) \cdot B^{-1} = B^\nu_\mu E_\nu (B) \cdot B^{-1}. \tag{6.6}$$

In particular, such are all holonomic frames in $T(E)$, locally induced by local coordinates on $E$. Now the normal frames equation (6.2) (or (6.1)) reduces to

$$(\Gamma_\mu \cdot B + E_\mu (B))_{\mathbb{p}(U)} = 0. \tag{6.7}$$

This equation leaves the frame $\{\tilde{E}_\mu = \pi_*|_{\Delta^h}(X_\mu)\}$ in $T(M)$ completely arbitrary and imposes restriction on the frame $\{\tilde{E}_\mu = V^{-1}(X_a) = B^h_a E_b\}$ in $E$. This conclusion justifies the following definition.

**Definition 6.1.** Given a linear connection $\Delta^h$ on a vector bundle $(E, \pi, M)$ and a subset $U_M \subseteq M$. A frame $\{E_a\}$ in $E$, defined over an open set $V_M$ containing $U_M$ or equal to it, $V_M \supseteq U_M$, is called normal for $\Delta^h$ over/on $U_M$, if there is a frame $\{X_I\}$ in $T(E)$, defined over an open set $V_E \subseteq E$, which is normal for $\Delta^h$ over a subset $U_E \subseteq E$ and such that $\pi(U_E) = U_M$, $\pi(V_E) = V_M$, and $E_a = V^{-1}(X_a)$, with the mapping $v$ defined by (3.14). Respectively, $\{E_a\}$ is normal for $\Delta^h$ along a mapping $g: Q_M \to M$, $Q_M \neq \emptyset$, if $\{E_a\}$ is normal for $\Delta^h$ over $g(Q_M)$.
Taking into account definition\textsuperscript{4.1} we see that the so-defined normal frames in the bundle space \(E\) are just the ones used in the theory of frames normal for linear connections in vector bundles\textsuperscript{[7–11]}.

It is quite clear, to any frame \(\{X_I\}\) in \(T(E)\) normal over \(U \subseteq E\), there corresponds a unique frame \(\{E_a = v^{-1}(X_a)\}\) in \(E\) normal over \(\pi(U) \subseteq M\). But, to a frame \(\{E_a\}\) in \(E\) normal over \(\pi(U)\), there correspond infinitely many frames \(\{X_I\} = \{((\pi_*|_{\Delta^h})^{-1}(E_\mu), v(E_a)\}\) in \(T(E)\) normal over \(U\), where \(\{E_\mu\}\) is an arbitrary frame in \(T(M)\) over \(\pi(U)\). Thus the problems of existence and (un)uniqueness of normal frames in \(T(E)\) is completely reduced to the same problems for normal frames in \(E\). The last kind of problems, as we noted at the beginning of the present section, are known and investigated and the reader is referred to \textsuperscript{[7–11]} for their solutions and further details.

Ending, we emphasize that a normal frame \(\{E_a\}\) in \(E\), as well as the basis \(\{v(E_a)\}\) for \(\Delta^v\), can be holonomic as well as anholonomic (see loc. cit.); at the same time, a normal frame \(\{X_I\}\) in \(T(E)\) is anholonomic unless some conditions hold, a necessary condition being the flatness (integrability) of the horizontal distribution \(\Delta^h\).

7. Conclusion

In Sect.\textsuperscript{4} we saw that the theory of normal frames in the most general case is quite trivial. This reflects the understanding that the more general a concept is, the less particular properties it has, but the more concrete applications it can find if it is restricted somehow. This situation was demonstrated when normal frames adapted to holonomic ones were considered; e.g. they exist at a given point or along an injective horizontal path, but on an open set they may exist only in the flat case. A feature of a vector bundle (e.g. they exist at a given point or along an injective horizontal path, but on an open set they sit, and in \(T(E)\) normal over \(U\)).

From here a conclusion was made that the theory of normal frames is quite trivial, if any, to be ‘lowered’ to ones in \(E\). From here a conclusion was made that the theory of frames in \(T(E)\) normal for linear connections on a vector bundle is equivalent to the existing one of frames in \(E\) normal for covariant derivatives in \((E, \pi, M)\)\textsuperscript{[10,11]}.

It should be emphasized, the importance of the normal frames for the physics comes from the fact that they are the mathematical object corresponding to the physical concept of inertial frame of reference\textsuperscript{[10,22,23]}.

Appendix: Coordinates normal along injective mappings with non-vanishing horizontal component

The purpose of this Appendix is a multi-dimensional generalization of proposition\textsuperscript{5.3} in the real case, \(\mathbb{K} = \mathbb{R}\). It is formulated below as theorem\textsuperscript{A.1} for its proof we shall need a result which is a multidimensional generalization of lemma\textsuperscript{5.4}.

**Lemma A.1.** Let \(n \in \mathbb{N}, M\) be a \(C^3\) manifold with \(\dim M \geq n\), \(J^n\) be an open set in \(\mathbb{R}^n\), and \(\gamma: J^n \rightarrow M\) be \(C^1\) regular injective mapping. For every \(s_0 \in J^n\), there exists a chart \((U_1, x)\) of \(M\) such that \(\gamma(s_0) \in U_1\) and \(x(\gamma(s)) = (s, t_0)\) for some fixed \(t_0 \in \mathbb{R}^{\dim M - n}\) and all \(s \in J^n\) such that \(\gamma(s) \in U_1\).

**Proof.** Let us choose arbitrary some \(s_0 \in J^n\) and a chart \((U, y)\) with \(U \ni \gamma(s_0)\) and \(y: U \rightarrow \mathbb{R}^{\dim M}\). Since the regularity of \(\gamma\) at \(s_0\) means that \(\left.\frac{\partial y_j}{\partial x^i}\right|_{s_0}\) has maximal rank, equal to \(n\), we, without loss of generality, can suppose the coordinates \(\{y^j\}\) to be taken such that...
In fact, we have \( \gamma_n(U_1) \subseteq J^n \) with \( J_1^n \ni s_0 \) and such that the matrix \( \left[ \frac{\partial \gamma^a}{\partial s^i} \right]_{s_0} \) is non-degenerate for \( s \in J_1^n \) and the mapping

\[
(\gamma_y^1, \ldots, \gamma_y^n)|_{J_1^n} : J_1^n \to (\gamma_y^1(J_1^n), \ldots, \gamma_y^n(J_1^n)) \subseteq \mathbb{R}^n,
\]

with \( (\gamma_y^1, \ldots, \gamma_y^n)|_{J_1^n} : s \to (\gamma_y^1(s), \ldots, \gamma_y^n(s)) \) for \( s \in J_1^n \), is a \( C^1 \) diffeomorphism. Define a chart \((U_1, x)\) of \( M \) with domain

\[
U_1 := \{ p \in U, \ y^a(p) \in \gamma_y^n(J_1^n), \ a = 1, \ldots, n \} = y^{-1}(\{(\gamma_y^1(J_1^n), \ldots, \gamma_y^n(J_1^n)) \times \mathbb{R}^{\dim M - n} \} \ni \gamma(s_0)
\]

(A.1a)

and local coordinate functions \( x^i \) given via

\[
y^a := (\gamma_y^a|_{J_1^n}) \circ (x^1, \ldots, x^n), \quad a = 1, \ldots, n
\]

\[
y^k := x^k + (\gamma_y^k)|_{J_1^n} \circ (x^1, \ldots, x^n) - t^k_0, \quad k = n + 1, \ldots, \dim M
\]

(A.1b)

where \((x^1, \ldots, x^n) : p \to (x^1(p), \ldots, x^n(p)), \ p \in U_1, \) and \( t^k_0 \in \mathbb{R} \) are constant numbers. Since \( \frac{\partial y^a}{\partial x^i} = \frac{\partial \gamma^a}{\partial s^i} \frac{\partial s^i}{\partial x^i} = \delta^a_k \) for \( k \geq n + 1, \) \( \frac{\partial y^k}{\partial x^i} = \frac{\partial \gamma^k}{\partial s^i} \frac{\partial s^i}{\partial x^i} \) for \( k \geq n + 1, \) and \( \frac{\partial y^k}{\partial x^i} = \delta^k_l \) for \( k, l \geq n + 1, \) the Jacobian of the change \( \{y^i\} \to \{x^i\} \) on \( U_1 \) is det \( \left[ \frac{\partial y^a}{\partial x^i} \right] \) = (det \( \left[ \frac{\partial y^a}{\partial s^i} \right] \)) \( -1 = 0, \infty. \)

Consequently \( x^i \) are really coordinate functions and \( x : U_1 \to J_1^n \times \mathbb{R}^{\dim M - n} \) is in fact coordinate homeomorphism.\(^{11}\) The coordinates \( \{x^i\} \) can be expressed through \( \{y^i\} \) explicitly. Indeed, writing the first raw of \( (A.1b) \) as

\[
(y^1, \ldots, y^n) = (\gamma_y^1|_{J_1^n}, \ldots, \gamma_y^n|_{J_1^n}) \circ (x^1, \ldots, x^n) = (\gamma_y^1, \ldots, \gamma_y^n)|_{J_1^n} \circ (x^1, \ldots, x^n)
\]

and using that \( (\gamma_y^1, \ldots, \gamma_y^n)|_{J_1^n} \) is a \( C^1 \) diffeomorphism and the second raw of \( (A.1b) \), we find (cf. \( 5.4 \))

\[
(x^1, \ldots, x^n) = ((\gamma_y^1, \ldots, \gamma_y^n)|_{J_1^n})^{-1} \circ (y^1, \ldots, y^n)
\]

\[
x^k = y^k - (\gamma_y^k|_{J_1^n}) \circ ((\gamma_y^1, \ldots, \gamma_y^n)|_{J_1^n})^{-1} \circ (y^1, \ldots, y^n) + t^k_0, \quad k \geq n + 1.
\]

(A.1b)

Using \( (A.1) \), we see that in \((U_1, x)\) the local coordinates of \( \gamma(s) \) for \( s = (s^1, \ldots, s^n) \in J_1^n \) are

\[
\gamma^a(s) := x^a(\gamma(s)) = s^a, \quad \gamma^k(s) := x^k(\gamma(s)) = t^k_0, \quad k \geq n + 1,
\]

(A.2)

i.e. \( x(\gamma(s)) = (s, t_0) \) for some fixed \( t_0 = (t_{n+1}^0, \ldots, t_{\dim M}^0) \in \mathbb{R}^{\dim M - n} \).

Thus, in the chart \((U_1, x)\) or the coordinates \( \{x^i\} \) constructed above, the first \( n \) coordinates of a point lying in \( \gamma(J^n) \), i.e. in \( \gamma(J_1^n) \), coincide with the corresponding parameters \( s^1, \ldots, s^n \) of \( \gamma \), the remaining coordinates, if any, being constant numbers. This conclusion allows locally, in \( U_1 \), the mapping \( \gamma \) to be considered as a representative of a family of mappings \( \eta(\cdot, t) : J_1^n \to M, \ t \in \mathbb{R}^{\dim M - n} \), defined by \( \eta(s, t) := x^{-1}(s, t) \) for \( (s, t) \in J_1^n \times \mathbb{R}^{\dim M - n} \). In fact, we have \( \gamma = \eta(\cdot, t_0) \) or \( \gamma(s) = \eta(s, t_0) \).\(^{12}\)

---

\(^{10}\) If we start from a chart \((U, z)\) for which the matrix \( \left[ \frac{\partial \gamma^a}{\partial z^b} \right]_{s_0} \) is degenerate, we can make a coordinate change \( \{z^i\} \to \{y^i\} \) with \( y^i = z^a_{\alpha_1, \ldots, \alpha_{\dim M}} \), where the integers \( \alpha_1, \ldots, \alpha_{\dim M} \) form a permutation of \( 1, \ldots, \dim M \), such that \( \left[ \frac{\partial \gamma^a}{\partial z^b} \right]_{s_0} \) is non-degenerate. (For the proof, see any book on matrices, e.g. [24, 25].) Further, we suppose that such a renumbering of the local coordinates is already done if required. (Cf. footnote \( ^{11} \).)

\(^{11}\) The so-constructed chart \((U_1, x)\) is, obviously, a multidimensional generalization of a similar chart defined in the proof of lemma \( 5.1 \) — see the paragraph containing equation \( 5.4 \).

\(^{12}\) In \([9]\) the existence of \( \eta \) is taken as a given fact without proof.
Let \((E, \pi, M)\) be a \(C^3\) bundle endowed with \(C^1\) connection \(\Delta^b\). Let \(k \in \mathbb{N}, k \leq \dim M\), and \(J^k\) be an open set in \(\mathbb{R}^k\). Consider a \(C^2\) regular injective mapping \(\beta: J^k \to E\) such that the vector fields \(\dot{\beta}_\alpha: s \mapsto \dot{\beta}_\alpha(s) := \frac{\partial \beta^b(s)}{\partial u^\alpha} \beta^b(s)\), with \(s := (s^1, \ldots, s^k) \in J^k\) and \(\alpha = 1, \ldots, k\), do not belong to the vertical distribution \(\Delta^v\), \(\dot{\beta}_\alpha(s) \notin \Delta^v\) for all \(s \in J^k\); in particular, the mapping \(\beta\) can be a horizontal mapping in a sense that \(\dot{\beta}_\alpha(s) \in \Delta^h\) for all \(s \in J^k\), but generally these vectors can have a vertical component too. Our aim is to find the integrability conditions for the normal frame/coordinates equation (5.1) and its solutions, if any, when \(U = \beta(J^k)\) for some subset \(J^k \subseteq J^k\).

Let us take some \(s_0 \in J^k\) and construct the chart \((U_1, u)\) with \(U_1 \supseteq \beta (s_0)\) provided by lemma A.1 with \(E\) for \(M\) and \(\beta\) for \(\gamma\). If \(J^k := \{ s \in J^k : \beta(s) \in U_1 \}\) and \(p \in U_1\), then there is a unique \((s, t) \in J^k_1 \times \mathbb{R}^{\dim E - k}\) such that \(p = \eta(s, t)\) with \(\eta := u^{-1}\), i.e. \(u^I(p) = s^I\) for \(I = 1, \ldots, k\) and \(u^I(p) = t^I\) for \(I = k + 1, \ldots, n + r\). Besides, we have \(u(\beta(s)) = (s, t_0)\) for all \(s \in J^k_1\) and some fixed \(t_0 \in \mathbb{R}^{\dim E - k}\). Since the vector fields \(\dot{\beta}_\alpha, \alpha = 1, \ldots, k\), are not vertical, we can construct the coordinates \(\{u^I\}\), associated to the chart \((U_1, u)\), so that they to be bundle coordinates on \(U_1\) (see the proof of lemma A.1). Thus on \(U_1\) we have bundle coordinates \(\{u^I\}\) such that

\[
\begin{align*}
(u^1(\eta(s, t)), \ldots, u^{n+r}(\eta(s, t))) := (s, t) & \in \mathbb{R}^{n+r}, \\
\quad s = (s^1, \ldots, s^k) \in J^k_1 & \quad t = (t^{k+1}, \ldots, t^{n+r}) \in \mathbb{R}^{n+r - k}.
\end{align*}
\]

Let the indices \(\alpha\) and \(\beta\) run from 1 to \(k\) and the indices \(\sigma\) and \(\tau\) take the values form \(k + 1\) to \(n\); we set \(\sigma = \tau = \emptyset\) if \(k = n\). Thus, we have \(u^\alpha(\eta(s, t)) = s^\alpha, u^\tau(\eta(s, t)) = t^\tau,\) and \(u^\sigma(\eta(s, t)) = t^\sigma\).

**Proposition A.1.** Under the hypotheses made above, the normal frame/coordinates equation (5.1) with \(U = \beta(J^k) = \beta(J^k) \cap U_1\) has solutions if and only if the system of equations

\[
\left(\frac{\partial \Gamma^b_\alpha}{\partial u^\beta} - \frac{\partial \Gamma^b_\beta}{\partial u^\alpha}\right)|_{\beta(s)} B^b_\alpha(s) + \Gamma^b_\alpha(\beta(s)) \frac{\partial B^b_\beta(s)}{\partial s^\beta} - \Gamma^b_\beta(\beta(s)) \frac{\partial B^b_\alpha(s)}{\partial s^\alpha} = 0,
\]

where \(\Gamma^b_\mu\) are the 2-index coefficients of \(\Delta^b\) in \(\{u^I\}\), has solutions \(B^b_\alpha: J^k_1 \to \mathbb{R}\) with \(\det[B^b_\alpha] \neq 0, \infty\). Besides, if such solutions exist, then all solutions of (5.1) are given on \(U_1\) by the formula

\[
\tilde{\eta}^\alpha(\eta(s, t)) = - \int_{s_1}^s B^b_\alpha(s) \Gamma^b_\alpha(\beta(s)) \, ds^\alpha
\]

\[
- B^b_\alpha(s) \Gamma^b_\mu(\beta(s)) [u^\mu(\eta(s, t)) - u^\mu(\beta(s))] + B^b_\alpha(s) [u^b(\eta(s, t)) - u^b(\beta(s))] + f^\alpha(\mu, \sigma; t, \eta)[u^\mu(\eta(s, t)) - u^\mu(\beta(s))] - f^\alpha(\nu, \beta; \eta)[u^\nu(\eta(s, t)) - u^\nu(\beta(s))],
\]

where \(s_1 \in J^k_1\) is arbitrarily fixed, \(B^b_\alpha\), with \(\det[B^b_\alpha] \neq 0, \infty\), are solutions of (A.4), and the functions \(f^\alpha(\mu, \sigma; t, \eta)\) and their first partial derivatives are bounded when \(t \to t_0\).

**Remark A.1.** As \(u^\alpha(\eta(s, t)) = u^\alpha(\beta(s)) = s^\alpha\) for all \(\alpha = 1, \ldots, k\), the terms with \(\mu, \nu = 1, \ldots, k\) in (A.5) have vanishing contribution.

**Remark A.2.** For \(k = 1\), we have \(\alpha = \beta = 1\), due to which the equations (A.4) are identically valid and proposition A.1 reduces to proposition (5.3).

**Proof.** To begin with, we rewrite (5.1) as

\[
\left(\frac{\partial \tilde{\eta}^\alpha}{\partial s^\beta}\right)|_{\beta(s)} = - \left(\frac{\partial \tilde{\eta}^\alpha}{\partial t^\beta}\right)|_{\beta(s)} \Gamma^b_\alpha(\beta(s)) \quad \left(\frac{\partial \tilde{\eta}^\alpha}{\partial t^\beta}\right)|_{\beta(s)} = - \left(\frac{\partial \tilde{\eta}^\alpha}{\partial s^\beta}\right)|_{\beta(s)} \Gamma^b_\alpha(\beta(s)).
\]
Introducing a non-degenerate matrix-valued function $[B^0_b]$ on $J^k_1$ by

$$B^a_b(s) = \left. \frac{\partial \tilde{u}^a}{\partial t^b} \right|_{\beta(s)} = \left. \frac{\partial \tilde{u}^a(s, t)}{\partial t^b} \right|_{t=t_0}, \quad (A.6)$$

we see that (5.1) is equivalent to

$$\left. \frac{\partial \tilde{u}^a}{\partial s^\alpha} \right|_{\beta(s)} = -B^a_b(s) \Gamma^b_{\alpha}\beta(s)) \quad \alpha = 1, \ldots, k \quad (A.7a)$$

$$\left. \frac{\partial \tilde{u}^\sigma}{\partial t^\sigma} \right|_{\beta(s)} = -B^a_b(s) \Gamma^b_{\alpha}\beta(s)) \quad \sigma = k + 1, \ldots, n. \quad (A.7b)$$

Expanding $\tilde{u}^a(\eta(s, t))$ into a Taylor’s polynomial up to second order terms relative to $(t - t_0)$ about the point $t_0$ and using (A.6) and (A.7), we get:

$$\tilde{u}^a(\eta(s, t)) = f^a(s) - B^a_b(s) \Gamma^b_{\alpha}\beta(s))|^{\eta - t_0} + \frac{1}{2} \frac{\partial f^a}{\partial u^\tau}(s; t; \eta)|^{\eta - t_0} \left|^{t - t_0} + \frac{\partial f^a}{\partial u^\tau}(s, t)|^{\eta - t_0} - u^b(\eta(s, t)) - u^b(\beta(s))\right.$$  

$$+ \frac{\partial f^a}{\partial u^\tau}(s; t; \eta)|^{\eta - t_0} - u^b(\beta(s))\right] \quad (A.8)$$

where $f^a$ and $f^a_{\mu\nu}$ are $C^1$ functions and $f^a_{\mu\nu}$ and their first partial derivatives are bounded when $t - t_0$. The equation (A.7a) is the only condition that puts some restrictions on $f^a$ and $B^a_b$ (besides $\det[B^0_b] \neq 0, \infty$). Inserting (A.8) into (A.7a) and using that $\beta(s) = \eta(s, t_0)$, we obtain

$$\frac{\partial f^a(s)}{\partial s^\alpha} = -B^a_b(s) \Gamma^b_{\alpha}\beta(s)) \quad (A.9)$$

Thus the initial normal coordinates equation (5.1), with $U = \beta(J^k_1)$, has solutions if and only if there exist solutions of (A.9) relative to $f^a$ and/or $B^a_b$. The integrability conditions for (A.9) are [26]

$$0 = \frac{\partial^2 f^a}{\partial s^\beta \partial s^\alpha} - \frac{\partial^2 f^a}{\partial s^\alpha \partial s^\beta} = -\frac{\partial}{\partial s^\beta} (B^a_b(s) \Gamma^b_{\alpha}(s)) + \frac{\partial}{\partial s^\alpha} (B^a_b(s) \Gamma^b_{\alpha}(s)) = \cdots$$

and coincide with (A.4), by virtue of $u^a(\beta(s)) = s^a$. This result concludes the proof of the fires part of the proposition.

If (A.4) admits solutions $B^a_b$ with $\det[B^a_b] \neq 0, \infty$, then the general solution of (A.9) is

$$f^a(s) = -\int_{s_1}^{s} B^a_b(s) \Gamma^b_{\alpha}(s)|s^\alpha d^\alpha \quad (A.10a)$$

where $R^a_{\alpha\beta}(\beta(s)) = 0 \quad s \in J^k_1$ and this solution is independent of the integration path in $J^k_1$, due to (A.4).

**Lemma A.2.** Let $(E, \pi, M)$ be a $C^3$ bundle endowed with $C^2$ connection with coefficients $\Gamma^c_{\mu\nu}$ in the frame adapted to local coordinates $\{u^\alpha\}$, defined before proposition A.7. There exist solutions $B^a_b$ with $\det[B^a_b] \neq 0, \infty$ of the system of equations (A.4) if and only if the coefficients $\Gamma^a_{\mu}$ satisfy the equations

$$R^a_{\alpha\beta}(\beta(s)) = 0 \quad s \in J^k_1 \quad (A.10a)$$

$$\left. \left( \frac{\partial^2 \Gamma^c_{\alpha\beta}}{\partial u^b \partial u^d} - \frac{\partial \Gamma^c_{\alpha\beta}}{\partial u^d} \frac{\partial \Gamma^c_{\alpha\beta}}{\partial u^b} \right) \right|_{\beta(s)} = 0 \quad s \in J^k_1 \quad (A.10b)$$

in which $R^a_{\alpha\beta}$ are the (fibre) components in $\{u^l\}$ of the curvature of $\Delta^b$, defined by (5.8).

If the conditions (A.10) are valid, the set of the solutions of (A.4) coincides with the set of solutions of the system

$$\frac{\partial B^a_b(s)}{\partial s^\alpha} = -B^a_c(s) \frac{\partial \Gamma^c_{\alpha}}{\partial u^b} \left|_{\beta(s)} + \frac{\partial D^a_b(s)}{\partial s^\alpha} \quad (A.11)$$
relative to $B^a_0$, where $D^a_0$ are solutions of
\[
\left( \Gamma^b_{\alpha}(\beta(s)) \frac{\partial}{\partial s^\beta} - \Gamma^b_{\beta}(\beta(s)) \frac{\partial}{\partial s^\alpha} \right) D^a_b(s) = 0. \tag{A.12}
\]

**Proof.** Consider the integrability condition (A.1) for (5.1) in more details. Define functions $D^a_{\alpha \beta} : J^1 \rightarrow \mathbb{K} = \mathbb{R}$ via the equation
\[
\frac{\partial B^a_{\alpha}(s)}{\partial s^\alpha} = -B^c_{\epsilon}(s) \frac{\partial \Gamma^c_{\epsilon}}{\partial u^b}_{\beta(s)} + D^a_{\alpha \beta}(s). \tag{A.13}
\]

The substitution of this equality into (A.4) results in
\[
R^a_{\alpha \beta}(\beta(s)) B^b_{\alpha}(s) - \Gamma^b_{\alpha}(\beta(s)) D^a_{\alpha \beta}(s) + \Gamma^b_{\beta}(\beta(s)) D^a_{\alpha \beta}(s) = 0,
\]

where $R^a_{\alpha \beta}$ are the (fibre) components in $\{u^b\}$ of the curvature of $\Delta^b$, defined by (5.1). The simple observation that $\{\tilde{u}^\alpha, \tilde{u}^a\}$, if they exist as solutions of (5.1), are normal coordinates on the whole bundle space of the restricted bundle $(U, \pi|_U, \pi(U))$ with $U = \beta(J^1)$ leads to
\[
R^a_{\alpha \beta}(\beta(s)) = 0 \quad s \in J^1, \tag{A.14}
\]
by virtue of proposition 5.4. Therefore the previous equation reduces to
\[
\Gamma^b_{\alpha}(\beta(s)) D^a_{\alpha \beta}(s) - \Gamma^b_{\beta}(\beta(s)) D^a_{\alpha \beta}(s) = 0. \tag{A.15a}
\]

It is clear that (A.13)–(A.15a) are equivalent to (A.4). Consequently, the quantities $D^a_{\alpha \beta}$ must be solutions of (A.15a) while the $C^1$ functions $B^a_0$ have to be solutions of (A.13). The integrability conditions
\[
\left( \frac{\partial^2 \Gamma^c_{\alpha}}{\partial u^b \partial u^d} - \frac{\partial^2 \Gamma^c_{\alpha}}{\partial u^d \partial u^b} \right) B^a_0(s) = 0 \quad \text{for (A.13)}
\]
can be written as
\[
\left( -\frac{\partial^2 \Gamma^c_{\alpha}}{\partial u^b \partial u^d} + \frac{\partial^2 \Gamma^c_{\beta}}{\partial u^b \partial u^d} \right) B^a_0(s) + \frac{\partial D^c_{\alpha \beta}}{\partial s^\beta} - \frac{\partial D^c_{\alpha \beta}}{\partial s^\alpha} = 0,
\]
which conditions split into
\[
0 = \frac{\partial D^a_{\alpha \beta}(s)}{\partial s^\alpha} - \frac{\partial D^a_{\alpha \beta}(s)}{\partial s^\beta}, \tag{A.15b}
\]

\[
0 = \left( -\frac{\partial^2 \Gamma^c_{\alpha}}{\partial u^b \partial u^d} + \frac{\partial^2 \Gamma^c_{\beta}}{\partial u^b \partial u^d} + \frac{\partial^2 \Gamma^c_{\beta}}{\partial u^b \partial u^d} - \frac{\partial^2 \Gamma^c_{\beta}}{\partial u^d \partial u^b} \right) \left| \frac{\partial D^c_{\alpha \beta}}{\partial s^\beta} + \frac{\partial D^c_{\alpha \beta}}{\partial s^\alpha} \right|_{\beta(s)}, \tag{A.16}
\]

where (A.14) and (A.15a) were applied in the derivation of the second equality in (A.16).

Since the system of equations (A.15) always has solutions, e.g., $D^a_{\alpha \beta}(s) = 0$, we can assert that (A.14) and (A.16) are the integrability conditions for (A.4) and, if (A.14) and (A.16) hold, every solution of (A.13), with $D^a_{\alpha}$, satisfying (A.15a), is a solution of (A.4) and vice versa.

At the end, the only unproved assertion is that $D^a_{\alpha \beta}$ in (A.13) equals to $\partial_\alpha(D^a_0)$ with $D^a_0$ satisfying (A.12). Indeed, since $J^1_1$ is an open set and hence is contractible one, the Poincaré’s lemma (see [27, sec. 6.3] or [28, pp. 21, 106]) implies the existence of functions $D^a_0$ on $J^1_1$ such that $D^a_{\alpha \beta}(s) = \partial_\alpha(D^a_0(s)$, due to (A.15b); inserting this result into (A.15a), we get (A.12).
Remark A.3. Regardless that the conditions \[ (A.10b) \] look quite special, they are identically valid for connections with
\[
\Gamma^a_\alpha = - (\Gamma^a_{b\alpha} \circ \pi) \cdot u^b + G^a_\alpha \circ \pi,
\]
where \( \Gamma^a_{b\alpha} \) and \( G^a_\alpha \) are \( C^2 \) functions on \( \pi(\beta(J^k)) \). In particular, of this kind are the linear connections on vector bundles — see proposition 3.1.

At last, we shall formulate the main result of the above considerations as a combination of proposition A.1 and lemma A.2.

Theorem A.1. Let \((E, \pi, M)\) be a \( C^3 \) bundle endowed with a \( C^2 \) connection. Under the hypotheses made and notation introduced before proposition A.1, there exist solutions of the normal frame/coordinates equation \((5.1)\) if and only if the connection’s coefficients satisfy the equations \((A.10)\). If these equations hold, all coordinates normal on \( \beta(J^k_1) \) are given on \( U_1 \) by \((A.5)\), where \( B^a_\alpha \) are solutions of \((A.11)\), with \( D^a_\alpha \) being solutions of \((A.12)\).

Remark A.4. If there are \( s_0 \in J^k \) and \( \alpha \in \{1, \ldots, k\} \) such that the vector \( \dot{\beta}_\alpha(s_0) \) is a vertical vector, \( \dot{\beta}_\alpha(s_0) \in \Delta^u_{\beta(s_0)} \), then theorem A.1 remains true with the only correction that the coordinates \( \{u^I\} \) will not be bundle coordinates. If this is the case, the constructed coordinates \( \{\tilde{u}^I\} \) will be solutions of \((5.1)\), but we cannot assert that they are bundle coordinates which are (locally) normal along \( \beta \) in a neighborhood of the point \( \beta(s_0) \).

Theorem A.1 provides a necessary and sufficient condition for the existence of local coordinates in a neighborhood of \( \beta(s_0) \) for any \( s_0 \in J^k \) which are locally normal along \( \beta \), i.e. on \( \beta(J^k_1) \) for some open subset \( J^k_1 \subseteq J^k \) containing \( s_0 \). Moreover, if this condition is valid, the theorem describes locally all coordinates normal along \( \beta \).

Theorem A.1 can be generalized by requiring \( \beta \) to be locally injective instead of injective, i.e. for each \( s \in J \) to exist subset \( J^k_s \subseteq J^k \) such that \( J^k_s \ni s \) and the restricted mapping \( \beta|_{J^k_s} \) to be injective. Besides, if one needs a version of the above results for complex bundles, they should be considered as real ones (with doubled dimension of the manifolds) for which are applicable the above considerations.
