Background: The relativistic three-body problem has a long tradition in few-nucleon physics. Calculations of the triton binding energy based on the solution of the relativistic Faddeev equation in general lead to a weaker binding than the corresponding non-relativistic calculation.

Purpose: In this work we solve for the three-body binding energy as well as the wave function and its momentum distribution. The effect of the different relativistic ingredients are studied in detail.

Method: Relativistic invariance is incorporated within the framework of Poincaré invariant quantum mechanics. The relativistic momentum-space Faddeev equation is formulated and directly solved in terms of momentum vectors without employing a partial-wave decomposition.

Results: The relativistic calculation gives a three-body binding energy which is about 3% smaller than its non-relativistic counterpart. In the wave function, relativistic effects are manifested in the Fermi motion of the spectator particle.

Conclusions: Our calculations show that though the overall relativistic effects in the three-body bound state are small, individual effects by themselves are not necessarily small and must be taken into account consistently.

PACS numbers: 21.45-v
We solve the relativistic three-nucleon bound-state problem and compare the resulting wave functions to the corresponding non-relativistic bound-state wave functions. While the wave functions themselves are not observable, the difference between the relativistic and non-relativistic wave functions provide useful information about which observables might be sensitive to the difference. Before going into details we need to define what we consider the relativistic three-nucleon problem, what we mean by relativistic effects, and summarize what has been learned from previous work on this problem.

In discussing the three-nucleon problem we limit our considerations to an idealized system modeled on a three-nucleon Hilbert space. This limitation allows us to make meaningful comparisons with the non-relativistic problem. The difference between a relativistic and non-relativistic model is the underlying symmetry group of the theory. For relativistic models the symmetry group is the Poincaré group and for non-relativistic models it is the Galilean group. Symmetries of a quantum theory preserve observables, (i.e. probabilities, expectation values and ensemble averages). This ensures the invariance of these observables in all inertial reference frames. In the relativistic case the inertial frames are related by Poincaré transformations while in the non-relativistic case inertial frames are related by Galilean transformations. Symmetries in a quantum theory are implemented by unitary or anti-unitary transformations. In the relativistic case the dynamics is implemented by a unitary projective representation of the Poincaré group [1]. In the non-relativistic case the dynamics is given by unitary projective representation of the central extension [2] of the Galilei group. Neither of these symmetries impose strong constraints on the dynamics. Normally the dynamics is formulated in a particular frame, e.g. the laboratory frame, the center-of-momentum (c.m.) frame, etc. The symmetry only ensures that the results are consistent in frames related to this particular frame by the symmetry transformations.

A second related constraint is cluster separability. In the three-body system cluster separability means that isolated one- and two-body subsystems should exhibit the same symmetries as the system itself. This is needed to ensure that either special or Galilean relativity can be tested on isolated subsystems. To understand the role of this condition assume, for example, that the two- and three-body dynamics are formulated in the two- and three-body rest frames respectively. The two-body subsystems in the three-body rest frame are not generally in the two-body rest frame. However, if the model satisfies cluster properties, then the two-body symmetry transformation determines how to transform the two-body subsystem from its rest frame to the three-nucleon rest frame. This embedding is different for the Galilean and Poincaré symmetry groups, and is the source of the relativistic effects that will be studied in this work.

One feature of realistic nucleon-nucleon (NN) interactions is that while they are formally motivated by e.g. meson-exchange models, when cast in a non-relativistic two-nucleon Hamiltonian, the model is adjusted so that the predicted NN observables agree with the experiment with a \( \chi^2 \) per degree of freedom close to 1 [3, 4]. The experimental data is consistent with special relativity while the non-relativistic calculation is consistent with a Galilean symmetry. There is an immediate question about what is being compared to the data to obtain the quoted \( \chi^2 \). The answer depends on how the analysis is performed. Normally laboratory frame data is correctly transformed to the c.m. frame using a Lorentz transformation. The correctly transformed scattering data is then compared to the non-relativistic c.m. scattering solutions. Parameters of the interaction are fine tuned to achieve agreement with the data. In this case phase shifts are identified as functions of the relativistic and non-relativistic relative momenta. This means that in any other frame the experimental and computed cross sections will no longer be identical functions of laboratory energy.

The important consequence of this is that in the preferred c.m. frame the non-relativistic two-body calculation gives the experimental result. It is also possible to introduce relativistic NN interactions that are consistent with the same scattering data. If one were to take the non-relativistic limit of the relativistic model the scattering observables would change as a result of the approximation and would not agree with the results of a non-relativistic model that is fit to the same experimental data. This aspect of realistic NN interaction must be taken into account when interpreting relativistic corrections in the three-body problem.

In this work we construct the relativistic NN interaction so that the rest-frame relativistic and non-relativistic NN wave functions and phase shifts are identical. Cluster properties determine how these two-body models should be embedded in the three-nucleon Hilbert space. Relativistic effects are due entirely to the different ways that these two-body interactions appear in the three-nucleon problem in order to satisfy cluster properties.

The resulting formulation of the relativistic three-nucleon problem has the property that in the limit that the momenta are all small compared to the nucleon masses, the relativistic Faddeev equation reduces to the non-relativistic one, which justifies our interpretation of the difference being attributed to “relativistic effects”. It is appropriate to think of the relativistic effects being due to the difference between relativistic and non-relativistic treatments of Fermi motion, which involve subsystem Galilean or Poincaré boosts respectively.

In this initial work the non-relativistic NN potential is a Malfliet-Tjon V [5] type interaction. The formal definition
of the phase and wave-function equivalent relativistic NN interactions that we use was given by Coester, Pieper and Serduke [6]. The construction of the corresponding relativistic NN transition operators was given in [7] and successfully implemented in [8–10]. The two-body unitary representation of the Poincaré group is formulated using a construction given by B. Bakmjian and L. H. Thomas [11]. The corresponding three-body unitary representation of the Poincaré group that satisfies S-matrix cluster properties was introduced by Coester [12]. Note that while it is possible to realize cluster properties of the unitary representation of the Poincaré group [13–15], for the three-body problem it is sufficient and far simpler to formulate a model where the S-matrix clusters properly. The difference is that cluster properties of the unitary representation of the Poincaré group requires three-body forces that are generated by the two-body forces. In the formulation where only the S matrix clusters the required three-body forces are replaced by two-body interactions that depend on the spectator momentum. The important relation is that both formulations of the relativistic three-body problem give identical three-body scattering observables. They are related by an S-matrix preserving unitary transformation that becomes the identity in the three-body rest frame [14].

While many of the methods mentioned in the previous paragraph are formulated using one of Dirac’s forms of dynamics [16], in our calculations the form of dynamics is only relevant if we choose to transform our results from the three-body rest frame to an arbitrary frame. This can be done consistently in any form of dynamics [17].

In this work we solve the relativistic Faddeev equation using direct integration [18–20]. This method gives the three-body wave function directly, so it does not have to be reconstructed using partial-wave methods. Part of our motivation for using direct integration in the bound-state problem is to provide test problems that can be compared to previous relativistic partial-wave calculations. Ultimately these calculations need to be extended to treat spin-dependent interactions and scattering at relativistic energies, where direct-integration methods are essential.

The first relativistic three-body calculations using the formalism that we use in this paper were performed by Glöckle, Coester, and Lee [21]. Their calculations used the same Malfliet-Tjon V (MT-V interaction. However, they approximated the relativistic interaction so the phase equivalence with the non-relativistic interaction was only approximate and they used a partial-wave expansion that was truncated to s-waves. They found a small decrease in the binding energy due to relativistic effects. Relativistic bound-state calculations with a realistic interaction were performed by Kamada et al. [22]. These were fully converged partial-wave calculations. The resulting binding energy corrections were comparable to the corrections obtained by Glöckle, Coester and Lee. Three-body scattering calculations using a realistic interaction and including a three-nucleon force were also performed using partial-wave methods for energies up to 250 MeV [23]. These calculations exhibited relativistic effects in the breakup observables and large-angle elastic scattering showed evidence of missing degrees of freedom. Direct integration scattering calculations were successfully performed using the MT-V interaction for energies up to 2 GeV [8–10]. These also exhibited strong relativistic effects in certain breakup observables and demonstrated the value of direct integration methods at higher energies. Our long term goal is to perform few-Gev scale scattering calculations with realistic interactions. This requires using direct integration with realistic interactions. Since there are no such calculations the first step it to establish that the methods works for the bound-state problem, where the results can be compared to partial-wave calculations. This work is a precursor to including a relativistic treatment with realistic interactions using direct integration methods.

This work addresses two omissions of the body of work discussed above. First there are no relativistic bound state calculations that have utilized direct integration methods. Second, while the three-body binding energy has been computed, there is no published work comparing the relativistic and non-relativistic bound-state wave functions. While wave functions are not directly observable, observables are sensitive to the structure of the wave functions and differences in the relativistic and non-relativistic wave functions are responsible for relativistic effects in three-body observables.

II. THE POINCARÉ INVARIANT FADDEEV EQUATION

A. Kinematic Variables

In both the relativistic and non-relativistic three-body problem Poincaré or Galilean symmetry relates the state of the system in its rest frame to its state in a general frame. The dynamics is usually formulated in the rest frame of the system. Thus it is useful to formulate the three-body problem using variables that describe the momenta of particles in the three-body rest frame. The two-body subsystem, on the other hand, uses variables that describe the momenta of particles in the rest frame of the subsystem. The relevant variables are defined by boosting the single-particle momenta to the three-body rest frame, and then boosting two-body subsystem momenta to the subsystem rest frame. Using Galilean boosts results in the Jacobi momenta that are used in non-relativistic three-body calculations [24]. Replacing the Galilean boosts by Lorentz boosts leads to relativistic Jacobi momenta. In both cases these are changes of variables from single-particle momenta to variables that are more convenient in three-body applications.
The vector components of $p$ defined by $P$ are the two-body invariant mass of the $(ij)$ pair, which should not be considered as approximations to a relativistic two-body model. Instead a realistic relativistic two-body interactions are already consistent with data and at the two-body parameters of the interaction must be fine tuned in order to be consistent with experimental two-body scattering observables. This means that the non-relativistic interactions are already consistent with data and at the two-body level should not be considered as approximations to a relativistic two-body model. Instead a realistic relativistic

$$k^\mu_i := \Lambda^{-1}(P/M_0)^\mu_\nu p^\nu_i.$$  
(1)

The vector components of $k_i^\mu$ are

$$k_i = p_i + \frac{P}{M_0} \left( \frac{P \cdot p_i}{M_0 + \sqrt{M_0^2 + P^2}} - \omega_m(p_i) \right),$$  
(2)

where $P$ is the three-vector part of $P^\mu$ and $\omega_m(p_i) = p^\mu_i = \sqrt{m^2 + p_i^2}$ is the energy of the $i$-th particle. The $k_i$ are not independent. They satisfy

$$\sum_{i=1}^{3} k_i = 0 \quad M_0 := \sum_{i=1}^{3} \omega_m(k_i).$$  
(3)

The other relativistic Jacobi momentum variables are obtained by boosting $k_i^\mu$ to the rest frame of the $(ij)$ pair. Following Eq. (2) we denote the four momentum of the pair $(ij)$ in the three-body rest frame by $k_{ij}^\mu = k_i^\mu + k_j^\mu$, and the two-body invariant mass of the $(ij)$ subsystem by $m_{0ij}^2 = -k_{ij}^\mu k_{\mu ij}$. The other relativistic Jacobi momenta are defined by

$$p_{ij}^\mu := \Lambda^{-1}(k_{ij}/m_{0ij})^\mu_\nu k_i^\nu.$$  
(4)

The vector components of $p_{ij}^\mu$ are

$$p_{ij} = k_i + \frac{k_{ij}}{m_{0ij}} \left( \frac{k_{ij} \cdot k_i}{m_{0ij} + \sqrt{m_{0ij}^2 + k_{ij}^2}} - (\omega_m(k_i)) \right).$$  
(5)

The inverse of Eq. (5) is given as

$$k_i = p_{ij} + \frac{k_{ij}}{m_{0ij}} + \left( \frac{k_{ij} \cdot p_{ij}}{m_{0ij} \sqrt{m_{0ij}^2 + k_{ij}^2}} + (\omega_m(p_{ij})) \right).$$  
(6)

The pairs $(k_i, p_{ij})$ are the relativistic analogs of the usual Jacobi momenta. If the Lorentz boosts $\Lambda^{-1}(\cdot)^\mu_\nu$ are replaced by Galilean boosts these become the non-relativistic Jacobi momenta [24].

The different choices of independent momentum variables are the single-particle momenta $\{p_1, p_2, p_3\}$, the total momentum plus the momenta of any two particles in the three-body rest frame, $\{P, k_i, k_j\}$ and the relativistic Jacobi momenta for the $jk$ pair, $\{P, k_i, p_{jk}\}$. The Jacobian of the variable change $\{p_1, p_2, p_3\} \leftrightarrow \{P, k_i, k_j\}$ is one when $P = 0$, while the Jacobian of the variable change $\{P, k_i, k_j\} \leftrightarrow \{P, k_i, p_{jk}\}$ is

$$\Lambda^2(k_i, k_j) := \left| \frac{\partial(k_i, k_j)}{\partial(p_{ij}, k_{ij})} \right| = \frac{\omega_m(p_{ij}) + \omega_m(p_{ij}) \omega_m(k_i) \omega_m(k_j)}{\omega_m(k_{ij}) + \omega_m(k_j) \omega_m(p_{ij}) \omega_m(p_{ij})}. $$

(7)

In the limit that the momenta are much smaller than the masses the relativistic Jacobi momenta become identical to the non-relativistic Jacobi momenta and the Jacobian becomes 1.

B. Two-Body Interactions Embedded in the Three-Body Space

Realistic two-body interactions may be e.g. motivated by meson exchange or other effective field theories, but the parameters of the interaction must be fine tuned in order to be consistent with experimental two-body scattering observables. This means that the non-relativistic interactions are already consistent with data and at the two-body level should not be considered as approximations to a relativistic two-body model. Instead a realistic relativistic
The two-body model should be consistent with the same data. Once the two-body model is defined, cluster properties dictate how the two-body interactions appear in the three-body problem. This is different in the relativistic and non-relativistic formalism.

Given a non-relativistic two-body model fit to scattering data, we define a relativistic interaction fit to the same data by requiring that the relativistic wave functions as a function of $p_{ij}$ are identical to the non-relativistic wave functions as a function of the corresponding non-relativistic Jacobi momentum. Since the phase shifts can be extracted from asymptotic properties of the wave functions; this ensures that both interactions give the same phase shifts as a function of the $p_{ij}$. This can be proved using the invariance principle [15, 25].

We begin by defining the interacting two-body invariant mass operator (relativistic rest-frame Hamiltonian) for the $ij$ pair in terms of the non-relativistic two-body interaction by

$$m_{jk}^2 = 4m\left(\frac{p_{jk}^2}{m} + v_{jk}^{nr} + m\right),$$

where $v_{jk}^{nr}$ is the non-relativistic nucleon-nucleon interaction between particles $j$ and $k$. Since $m_{jk}^2$ is a function of the non-relativistic rest-frame Hamiltonian, $p_{jk}^2/m + v_{jk}^{nr}$, it has the same eigenfunctions. The phase-equivalent relativistic interaction, $v_{jk}^r$, is defined in terms of $m_{jk}$ by

$$v_{jk}^r = m_{jk} - m_{0jk}. \quad (9)$$

While it is possible to formally solve the non-linear relation needed to express $v_{jk}^r$ in terms of $v_{jk}^{nr}$ [26], this is not needed to formulate the relativistic Faddeev equation.

The input to the Faddeev equation is the two-body transition operators properly embedded in the three-body Hilbert space. As in the two-body case we define interactions as the difference between the three-body mass operator leads to the same two-body scattering operator as the two-body mass operator $m_{ij}^2$. This will be true if we can write the three-body interacting mass operator with pair $ij$ interacting as a function of $m_{ij}$. This can be achieved by defining

$$M_{jk} = \sqrt{k_i^2 + m_{jk}^2 + \omega_m(k_i)} = \sqrt{k_i^2 + 4m^2 + 4p_{jk}^2 + 4mv_{jk}^{nr} + \omega_m(k_i)}. \quad (10)$$

The two-body interactions embedded in the three-body Hilbert space are

$$V_{jk} = M_{jk} - M_0 = \sqrt{k_i^2 + 4m^2 + 4p_{jk}^2 + 4mv_{jk}^{nr}} - \sqrt{k_i^2 + 4m^2 + 4p_{jk}^2}. \quad (12)$$

The three body-bound states are eigenstates of the three-body mass operator

$$M_t = M_0 + V_{12} + V_{23} + V_{31}. \quad (13)$$

The Faddeev kernel involves the two-body transition operators $T_{jk}(z)$ that act in the three-particle Hilbert space. They are defined by

$$T_{jk}(z) := V_{jk} + V_{jk}(z - M_{jk})^{-1}V_{jk}. \quad (14)$$

This is a function of the non-relativistic two-body interaction between particles $j$ and $k$. Because of this relation, matrix elements of $T_{jk}(z)$ can be obtained directly from the non-relativistic two-body transition matrix elements using a two-step process. This method is exact and avoids the problem of computing the relativistic two-body interaction.

The first step is to use the general relation between the interaction, scattering wave functions and half-shell transition operators

$$V_{jk}|(k_i, p_{jk})^+\rangle = T_{jk}(z_0)|k_i, p_{jk}\rangle, \quad (15)$$

where $z_0 = \sqrt{m_{0jk}^2(p_{jk})^2 + k_i^2 + i0^+}$ is the on-shell energy. Using the relativistic and non-relativistic versions of this relation leads to the identity

$$T_{jk}\left(p_{jk}, p_{jk}'; \sqrt{m_{0jk}^2(p_{jk}')^2 + k_i^2 + i0^+}\right) = F(p_{jk}, p_{jk}'; k_i)t_{nr}\left(p_{jk}, p_{jk}'; \frac{p_{jk}^2}{m} + i0^+\right),$$

with

$$T_{jk}(z_0) = \left(p_{jk}, p_{jk}'; \sqrt{m_{0jk}^2(p_{jk}')^2 + k_i^2 + i0^+}\right).$$

This completes the formalization of the three-body problem in a relativistic framework.
where the ratio of the half-shell transition matrix elements is

$$F(p_{jk}, p'_{jk}, k_i) = \frac{4m}{\sqrt{m_{0jk}^2(p_{jk}) + k^2_i + \sqrt{m_{0jk}^2(p'_{jk}) + k^2_i}}}.$$  

(17)

$$m_{0jk}(p_{jk}) = 2\omega_m(p_{jk})$$ and

$$\langle p_{jk}, k_i | T_{jk}(z) | p'_{jk}, k'_i \rangle = \delta(k_i - k'_i)T_{jk} (p_{jk}, p'_{jk}, z - \omega_m(k_i)).$$  

(18)

Equation (16) can be used to express $T_{jk} (p_{jk}, p'_{jk}; z - \omega_m(k_i))$ in terms of $t_{nr} (p_{jk}, p'_{jk}; p_{jk}'_m + i0^+)$. The only problem with this relation is that it is only valid for half-on-shell transition matrices. In the Faddeev equation $T_{jk} (p_{jk}, p'_{jk}; z)$ is needed for off-shell values of $z$.

These can be obtained by solving the integral equation for $T_{jk} (p_{jk}, p'_{jk}; z)$ that uses Eq. (16) as input

$$T_{jk} (p_{jk}, p'_{jk}; z - \omega_m(k_i)) = T_{jk} (p_{jk}, p'_{jk}; \sqrt{m_{0jk}^2(p'_{jk}) + k^2_i + i0^+})$$

$$+ \int dp''_{jk} \left[ \frac{1}{z - \sqrt{m_{0jk}^2(p''_{jk}) + k^2_i}} - \frac{1}{\sqrt{m_{0jk}^2(p'_{jk}) + k^2_i - \sqrt{m_{0jk}^2(p''_{jk}) + k^2_i + i0^+}}} \right]$$

$$\times T_{jk} (p_{jk}, p''_{jk}; z - \omega_m(k_i)) T_{jk} (p''_{jk}, p'_{jk}; \sqrt{m_{0jk}^2(p'_{jk}) + k^2_i + i0^+}).$$  

(19)

This equation, which follows from the first resolvent equations, is derived in the appendix. Thus, in order to compute the relativistic Faddeev kernel one only needs to solve the integral equation, Eq. (19), for $T_{jk} (p_{jk}, p''_{jk}; z - \omega_m(k_i))$, which uses the non-relativistic half-on-shell transition matrix elements as input.

**C. Faddeev Equations**

The relativistic three-body bound state is a discrete eigenstate of the relativistic three-body mass operator $M$ defined in (13). The eigenvalue problem can be reformulated as a system of coupled integral equations for the Faddeev components of the wave functions. For identical particles this reduces to a single equation for one of the Faddeev components

$$|\psi_i\rangle = |\psi_{jk,i}\rangle = (M_t - M_0)^{-1} T_{jk}(M_t) P |\psi_i\rangle,$$  

(20)

where $M_t = E_t + 3m$ is three-body mass eigenvalue, and $P = P_{12}P_{23} + P_{13}P_{23}$ are the standard permutation operator for three identical particles. This equation has non-zero solutions when $M_t$ is an eigenvalue of Eq. (13). The bound state wave function can be constructed from the solution of (20) using

$$|\Psi\rangle = |\psi_i\rangle + P |\psi_i\rangle.$$  

(21)

For the explicit solution we write them in the basis $|k_i, p_{jk}\rangle$, where $i$ is fixed. In this basis Eq. (20) has the form

$$\langle p_{jk}, k_i | \psi_i \rangle = \int dp'_{jk} dp'_{jk} dk'_{jk} dk''_{jk} \delta(k_i - k'_j) T_{jk} (p_{jk}, p'_{jk}; M_t - \omega_m(k_i))$$

$$\langle p'_{jk}, k'_j | p''_{jk}, k''_j \rangle \langle p''_{jk}, k''_j | P | p''_{jk}, k''_j \rangle \langle p''_{jk}, k''_j | |\psi_i\rangle$$

$$= \frac{1}{M_t - M_0(p_{jk}, k_i)} \int dp'_{jk} dp'_{jk} dk'_{jk} dk''_{jk} \delta(k_i - k'_j) T_{jk} (p_{jk}, p'_{jk}; M_t - \omega_m(k_i))$$

$$\times (\langle p'_{jk}, k'_j | p''_{jk}, k''_j \rangle + \langle p'_{jk}, k'_j | p''_{jk}, k''_j \rangle) \langle p''_{jk}, k''_j | |\psi_i\rangle.$$  

(22)

Here the permutation operators contain two delta functions which eliminate two of the integrals. We use them to eliminate the integrals over $p''_{jk}$ and $p'_{jk}$. The matrix elements of the permutation operators have the form

$$\langle p'_{jk}, k'_j | P | p''_{jk}, k''_j \rangle = \langle p'_{jk}, k'_j | p''_{jk}, k''_j \rangle + \langle p'_{jk}, k'_j | p''_{jk}, k''_j \rangle.$$
Inserting Eq. (24) into Eq. (22) and integrating over the delta functions leads to the relativistic Faddeev integral equation

\[
\langle p'_{jk}, k'|\psi_i \rangle = \frac{1}{M_t - M_0(p_{jk}, k_i)} \int d \kappa'_i N(k_i, i') T_{jk}^{sym}(p_{jk}; \hat{\pi}; M_t - \omega_m(k_i)) \langle i', \kappa'_i | \psi_i \rangle,
\]

where \( T_{jk}^{sym} \) is the symmetrized boosted two-body \( T \)-matrix, defined by

\[
T_{jk}^{sym}(p_{jk}, p'_{jk}; \epsilon) = T_{jk}(p_{jk}, p'_{jk}; \epsilon) + T_{jk}(-p_{jk}, p'_{jk}; \epsilon).
\]

and

\[
\hat{\pi} = p_{jk}(k'_i, -k_i - k'_i) = k'_i + \frac{1}{2} C(k_i, k'_i) k_i,
\]

\[
\pi = p_{jk}(k_i + k'_i, -k'_i) = k_i + \frac{1}{2} C(k'_i, k_i) k'_i.
\]

The coefficient \( C(k_i, k'_i) \) is defined as \( \gamma \)

\[
C(k_i, k'_i) = 1 + \frac{\omega_m(k'_i) - \omega_m(|k_i + k'_i|)}{\omega_m(k'_i) + \omega_m(|k_i + k'_i|) + \sqrt{\omega_m(k'_i) + \omega_m(|k_i + k'_i|)}^2 - k_i^2}.
\]

In deriving Eq. (26) we used the property

\[
\langle p_{jk}, k_i |\psi_i \rangle = -\langle -p_{jk}, k_i |\psi_i \rangle.
\]

The relativistic momenta \( \hat{\pi} \) and \( \pi \) defined in Eq. (28) become the corresponding non-relativistic ones if the coefficient \( C(k_i, k'_i) \) is equal to one, which is the case if the momenta are small with respect to the masses.

To solve the integral equation Eq. (26), we follow Ref. [18] and choose a coordinate system where \( k_i \) is parallel to \( z \)-axis and \( p_{jk} \) is in the \( x \)-\( z \) plane. Then the variables that appear in the Faddeev integral equation are magnitudes of the vectors as well as angles between them. They are

\[
x \equiv x_{p_{jk}} = \hat{k}_i \cdot \hat{p}_{jk},
\]

\[
x' \equiv x_{k'_i} = \hat{k}_i \cdot \hat{k}'_i,
\]

\[
y \equiv x_{p_{jk} k'_i} = \hat{p}_{jk} \cdot \hat{k}'_i = xx' + \sqrt{1 - x^2} \sqrt{1 - x'^2} \cos(\phi_{k'_i}),
\]

\[
\hat{\pi} = \sqrt{\frac{1}{4} C^2(k_i, k'_i, x_{q''} k'^2 + k'^2 + C(k_i, k'_i, x_{q''}) k_i k'_i x_{q''}}}
\]

\[
\pi = \sqrt{\frac{1}{4} C^2(k_i, k'_i, x_{q''} k'^2 + k'^2 + C(k_i, k'_i, x_{q''}) k_i k'_i x_{q''}}}
\]
\[
\pi = \sqrt{k_i^2 + \frac{1}{4}C^2(k_i', k_i, x_{ki})k_i'^2 + C(k_i', k_i, x_{ki})k_ik_i'},
\]
\[
x_{pjk} = \frac{x_{pjk} + \pi}{\pi}k_i(k_i', k_i, x_{ki'}),
\]
\[
x_{\pi k_i} = \frac{x_{\pi k_i}}{\pi} = \frac{k_i k_i'}{\pi}C(k_i', k_i, x_{ki'})k_i'.
\]  

Using these variables, Eq. (26) takes the explicit form
\[
\langle p_{jk}, k_i | x_{pjk} | \psi_i \rangle = \frac{1}{M_t - \omega_m(k_i) - m_{0ijk}(p_{jk}) + k_i^2} \int_0^\infty dk_i' k_i'^2 \int_{-1}^1 dx_{ki'} \int_{-1}^1 d\phi_{ki'} \times N(k_i, k_i', x_{ki'}) T_{ijk}^{sym}(p_{jk}, \pi, x_{pjk}; M_t - \omega_m(k_i))(\pi, k_i', x_{\pi k_i} | \psi_i).
\]  

To solve Eq. (32), which has the form \( \lambda \chi = K(M_t)x \), we treat it as eigenvalue problem of the form \( \lambda x = K(M_t)x \) and vary \( M_t \) until \( \lambda = 1 \) to a given precision.

\[\text{D. Three-Body Wave Function}\]

Once the Faddeev component \( \langle p_{jk}, k_i | \psi_i \rangle \) is calculated, the three-body wave function can be obtained from Eq. (21) as
\[
\langle p_{jk}, k_i | \psi_i \rangle = \langle p_{jk}, k_i | \psi_i \rangle + \left[ \frac{\partial (p_{jk}, k_i)}{\partial (p_{ij}, k_i)} \right]^{1/2} \langle p_{ij}, k_i | \psi_i \rangle + \left[ \frac{\partial (p_{ij}, k_i)}{\partial (p_{jk}, k_i)} \right]^{1/2} \langle p_{ijk}, k_i | \psi_i \rangle,
\]  

where the Jacobi momenta in systems \((ki, j)\) and \((ij, k)\) are connected to the ones in system \((jk, i)\), i.e. \(p_{jk}, k_i\), by
\[
k_j = p_{jk} + \frac{k_i}{m_{0jk}} \left( \frac{k_i \cdot p_{jk}}{m_{0jk} + \sqrt{m_{0jk}^2 + k_i^2}} - \omega_m(p_{jk}) \right),
\]
\[
k_k = -k_i - k_j = -k_i - p_{jk} - \frac{k_i}{m_{0jk}} \left( \frac{k_i \cdot p_{jk}}{m_{0jk} + \sqrt{m_{0jk}^2 + k_i^2}} - \omega_m(p_{jk}) \right),
\]
\[
p_{ij} = k_i + \frac{k_k}{m_{0ij}} \left( \frac{k_k \cdot k_i}{m_{0ij} + \sqrt{m_{0ij}^2 + k_k^2}} + \omega_m(k_i) \right),
\]
\[
p_{ki} = k_k + \frac{k_j}{m_{0ki}} \left( \frac{k_j \cdot k_k}{m_{0ki} + \sqrt{m_{0ki}^2 + k_j^2}} + \omega_m(k_k) \right),
\]  

with
\[
m_{0ij} = \sqrt{(\omega_m(k_i) + \omega_m(k_j))^2 - k_k^2},
\]
\[
m_{0ki} = \sqrt{(\omega_m(k_i) + \omega_m(k_k))^2 - k_j^2}.
\]  

The Jacobians for changing the basis states from system \((jk, i)\) to \((ki, j)\) and \((ij, k)\) are
\[
\left[ \frac{\partial (p_{jk}, k_i)}{\partial (p_{ij}, k_i)} \right] = \left[ \frac{\partial (p_{jk}, k_i)}{\partial (p_{ij}, k_i)} \right] \left[ \frac{\partial (k_i, k_i)}{\partial (k_i, k_i)} \right] \left[ \frac{\partial (k_i, k_i)}{\partial (p_{ij}, k_i)} \right] = \frac{N^2(k_i, k_k)}{N^2(k_i, k_k)}.
\]
\[
\left[ \frac{\partial (p_{jk}, k_i)}{\partial (p_{ij}, k_i)} \right] = \left[ \frac{\partial (p_{jk}, k_i)}{\partial (p_{ij}, k_i)} \right] \left[ \frac{\partial (k_i, k_i)}{\partial (k_i, k_i)} \right] \left[ \frac{\partial (k_i, k_i)}{\partial (p_{ij}, k_i)} \right] = \frac{N^2(k_i, k_j)}{N^2(k_i, k_j)}.
\]

The Jacobi momenta in Eq. (34) can be explicitly given as a function of the Jacobi momenta of system \((jk, i)\),
\[
k_j = p_{jk} + \alpha k_i,
\]
\[
k_k = -p_{jk} - \beta k_i,
\]
\[ \mathbf{p}_{ij} = \gamma_p \mathbf{p}_{jk} + \gamma_k \mathbf{k}_i, \]
\[ \mathbf{p}_{ki} = \xi_p \mathbf{p}_{jk} + \xi_k \mathbf{k}_i, \]

where
\[
\alpha = \frac{1}{m_{0jk}} \left( \frac{p_{jk} k_i x_{p_{jk}}}{m_{0jk} + \sqrt{m_{0jk}^2 + k_i^2}} - \frac{1}{2} m_{0jk} \right),
\]
\[
\beta = 1 + \alpha,
\]
\[
\gamma_p = \frac{1}{m_{0ij}} \left( \frac{p_{jk} k_i x_{p_{jk}} + \beta k_i^2}{m_{0ij} + \sqrt{m_{0ij}^2 + k_i^2}} + m_{0i} \right),
\]
\[
\gamma_k = 1 + \gamma_p \beta,
\]
\[
\xi_p = -1 - \frac{1}{m_{0ki}} \left( \frac{p_{jk}^2 + \alpha \beta k_i^2 + (\alpha + \beta) p_{jk} k_i x_{p_{jk}}}{m_{0ki} + \sqrt{m_{0ki}^2 + k_i^2}} - m_0 \right),
\]
\[
\xi_k = \alpha (\xi_p + 1) - \beta.
\]

In the coordinate system defined by Eq. (31), the relativistic three-body wave function of Eq. (33) has the form
\[
\langle p_{jk}, k_i, x_{p_{jk}} | \Psi \rangle = \langle p_{jk}, k_i, x_{p_{jk}} | \psi_\text{i} \rangle + \frac{N(k_j, k_k)}{N(k_i, k_k)} \langle p_{ki}, k_j, x_{p_{ki}, k_j} | \psi_\text{i} \rangle + \frac{N(k_i, k_j)}{N(k_i, k_k)} \langle p_{ij}, k_k, x_{p_{ij}, k_k} | \psi_\text{i} \rangle,
\]

with
\[
p_{ki} = | \mathbf{p}_{ki} | = | \xi_p \mathbf{p}_{jk} + \xi_p \mathbf{k}_i | = \sqrt{\xi_p^2 p_{jk}^2 + \xi_k^2 k_i^2 + 2 \xi_p \xi_k p_{jk} k_i x_{p_{jk}}},
\]
\[
k_j = | \mathbf{k}_j | = | \mathbf{p}_{jk} + \alpha \mathbf{k}_i | = \sqrt{p_{jk}^2 + \alpha^2 k_i^2 + 2 \alpha p_{jk} k_i x_{p_{jk}}},
\]
\[
x_{p_{ki}, k_j} \equiv \mathbf{p}_{ki} \cdot \mathbf{k}_j = \xi_p p_{jk}^2 + \alpha \xi_k k_i^2 + (\alpha \xi_p + \xi_k) p_{jk} k_i x_{p_{jk}},
\]
\[
p_{ij} = | \mathbf{p}_{ij} | = | \gamma_p \mathbf{p}_{jk} + \gamma_k \mathbf{k}_i | = \sqrt{\gamma_p^2 p_{jk}^2 + \gamma_k^2 k_i^2 + 2 \gamma_p \gamma_k p_{jk} k_i x_{p_{jk}}},
\]
\[
k_k = | \mathbf{k}_k | = | - \mathbf{p}_{jk} - \beta \mathbf{k}_i | = \sqrt{p_{jk}^2 + \beta^2 k_i^2 + 2 \beta p_{jk} k_i x_{p_{jk}}},
\]
\[
x_{p_{ij}, k_k} \equiv \mathbf{p}_{ki} \cdot \mathbf{k}_j = -\gamma_p p_{jk}^2 + \beta \gamma_k k_i^2 + (\beta \gamma_p + \gamma_k) p_{jk} k_i x_{p_{jk}}.
\]

### III. RESULTS AND DISCUSSION

#### A. Binding Energy

To evaluate the relativistic effects in the three-body binding energy we use the Malffiet-Tjon V [5] potential,
\[
\langle \mathbf{p}_{ij} | \nu^{nr} | \mathbf{p}_{ij} \rangle = \frac{1}{2 \pi^2} \left( \frac{V_R}{(\mathbf{p}_{ij} - \mathbf{p}_{ij})^2 + \mu_R^2} - \frac{V_A}{(\mathbf{p}_{ij} - \mathbf{p}_{ij})^2 + \mu_A^2} \right),
\]

with parameters given in in Ref. [18]. In addition, we use \( \hbar^2 / m = 41.470 \text{ MeV fm}^2 \) and \( \hbar c = 197.3286 \text{ MeV fm} \). In order to numerically solve Eq. (32), the integrals over the continuous momenta and angle variables are replaced by sums over discrete quadrature points. To reach five significant digit convergence in binding energy we use 100 Gaussian quadrature points for the Jacobi momentum \( p_{jk} \) on the interval \([0, 60 \text{ fm}^{-1}]\), 60 quadrature points for Jacobi momentum \( k_i \) on the interval \([0,20 \text{ fm}^{-1}]\), and 40 quadrature points for the angle variables. The Faddeev integral equation, Eq. (32), is solved by iteration using a Lanczos algorithm [27]. The iteration of this integral equation requires a large number of two-dimensional interpolations on the Faddeev component and symmetrized two-body \( t \)-matrix. We performed the interpolation using cubic-Hermite splines of Ref. [28]. Seven iterations are sufficient to search for the mass eigenvalue with a relative error of \( 10^{-6} \).

The off-shell \( T \)-matrix, which is needed as input for the Faddeev integral equation, is computed by solving Eq. (A10). The input is the right-half-shell \( T \)-matrix embedded in the three-body Hilbert space, which is analytically obtained from the non-relativistic \( T \)-matrix by Eq. (16). In Fig. 1 we plot the ratio \( F(p_{jk}, p_{jk}', k_i) \) defined in Eq. (17) of these
two transition operators as a function of momenta $p_{jk}$ and $p'_{jk}$ for third particle momentum $k_i = 5 \text{ fm}^{-1}$. The slope of this function decreases as the value of $k_i$ increases.

As a numerical test of the solution of first resolvent integral equation for negative energies, we reproduce the same non-relativistic three-body binding energy as obtained from the direct solution of the Lippmann-Schwinger (LS) equation for the off-shell $T$-matrix within four significant figures. The imaginary part of the transition matrix calculated from the first resolvent equation is of the order of $10^{-11} \text{ MeV}^{-2}$, which is $10^4$ times smaller than the real part, which gives an additional measure of the accuracy of the calculation.

In order to graphically analyze the Jacobian function $N(k_i,k'_r,x_{kr})$, which appears directly in the kernel of Faddeev integral equation, we parameterize it as $N(k \cos(\theta), k \sin(\theta), x \equiv x_{kr})$, and plot it as a function of $\theta$ and $x$ for $k = 1, 5, 10$ and $20 \text{ fm}^{-1}$. We use the same representation for the matrix elements of permutation coefficient $C(k \cos(\theta), k \sin(\theta), x \equiv x_{kr})$ shown in Fig 3.

The difference between the relativistic and non-relativistic calculations come from (1) the Jacobian function $N$, (2) the permutation coefficient $C$, (3) the relation between the relativistic and non-relativistic $T_{ij}(z)$ and (4) the relations between the relativistic and non-relativistic free Green functions. If we keep leading non-zero terms in the limit that the masses are larger than the momenta, all four of these factors reduce to the corresponding non-relativistic quantities. For the off-shell transition matrix, the kernel of the first resolvent equation reduces to the non-relativistic kernel in the same limit, which implies that both the half-shell and off-shell two-body transition matrix elements approach non-relativistic counterparts. The fact that all four corrections become small in that limit suggests that momentum/mass expansions are valid approximations. However, the corrections that relate the relativistic and non-relativistic Faddeev equation are only due to relativistic effects associated with a relativistic treatment of the Fermi motion with respect to the spectator particle. It would be incorrect to apply these expansions to the two-body dynamics, which are fit to the same data in both the relativistic and non-relativistic case.

While our calculations suggest that relativistic effects are small, it is important to remember is that only the combination of all four ingredients leads to a small correction, while individually the corrections do not have to be small. In Table I the contributions of the Jacobian function $N$ and the permutation coefficient $C$ to the relativistic three-body binding energy are shown. Both of these functions become 1 in the non-relativistic limit. By setting the Jacobian function $N$ to 1 in our relativistic calculations, the binding energy increases about 0.8%. Setting the permutation coefficient $C$ to 1 leads to a small decrease, about 0.6% of the binding energy. Finally, by setting both, the Jacobian function $N$ and the permutation coefficient $C$ to 1, the three-body binding energy has a small increase of about 0.15%. This means that ignoring the Jacobian function $N$ and the permutation coefficient $C$ in the relativistic formalism, leads to less than 0.2% over-binding. The combined effect of the Jacobian and permutation operators is a factor of 4-5 smaller than the effect of each one individually. The main contribution of relativistic effects in the three-body binding energy comes from the relativistic transition operator and free propagator. To evaluate the contribution of relativistic $T$-matrix to the three-body binding energy, we replace the relativistic $T$-matrix by non-relativistic one in the kernel of relativistic Faddeev integral equation. This substitution results in an increase of about 2.4% in the energy. When replacing the relativistic free propagator the by non-relativistic one, a decrease of 1.8% in relativistic 3B binding energy can be observed. These numerical results imply that the main contribution of relativistic effects in three-body binding energy results from the relativistic $T$-matrix. The remaining contribution stem from the free propagator, the Jacobian function and the permutation coefficient.

### B. Three-body Wave Function and Momentum Distribution

Using the Faddeev component from Eq. (32) the total wave function $\Psi(p_{jk}, k_i, x_{pjk})$ can be obtained by three-dimensional interpolations on momentum and angle variables, as shown in Eq. (39). The wave function is normalized as

$$\langle \Psi | \Psi \rangle = 8\pi^2 \int_0^\infty dp_{jk} p_{jk}^2 \int_0^\infty dk_i k_i^2 \int_{-1}^{+1} dx_{pjk} \Psi^2(p_{jk}, k_i, x_{pjk}) = 1.$$  \hspace{1cm} (42)

The left panel of Fig. 4 shows contour plots of the logarithm of the absolute value of the relativistic total wave functions for fixed angle $x_{pjk} = 0$ (top left) and $x_{pjk} = +1$ (bottom left). The right panel shows the difference between the relativistic and corresponding non-relativistic wave functions. These figures indicate that the largest relativistic effect appear at large values of the momentum of third particle $k_i$. This is not surprising, since the primary relativistic effects are expected to be due to the Fermi motion.
In order to simplify our analysis of the three-body wave function and to provide insight on the structure of wave function, we calculate the momentum distribution function \( n(k_i) \), the probability to find a particle with momentum \( k_i \) in the nucleus, and \( n(p_{jk}) \), the probability to find a pair with momentum \( p_{jk} \) in the nucleus, which are defined as

\[
\begin{align*}
n(k_i) &= 8\pi^2 k_i^2 \int_0^\infty dk_i k_i \int_{-1}^{+1} dx_{p_{jk}} \Psi^2(p_{jk}, k_i, x_{p_{jk}}), \\
n(p_{jk}) &= 8\pi^2 p_{jk}^2 \int_0^\infty dp_{jk} p_{jk}^2 \int_{-1}^{+1} dx_{p_{jk}} \Psi^2(p_{jk}, k_i, x_{p_{jk}}).
\end{align*}
\]

Electron scattering is sensitive to the quantity \( n(k_i) \). By considering the normalization of total wave function, given in Eq. (42), both momentum distribution functions are also normalized to one, i.e. \( \int_0^\infty n(p_{jk}) dp_{jk} = 1 \) and \( \int_0^\infty n(k_i) dk_i = 1 \). The momentum distribution functions \( n(p_{jk}) \) and \( n(k_i) \) calculated from relativistic and non-relativistic wave functions are presented in Fig. 5. The difference between relativistic and non-relativistic momentum distribution functions appears to be very small, but as we have shown in Fig. 6, the differences for both \( n(p_{jk}) \) and \( n(k_i) \) have a peak at \( p_{jk} \sim 0.2 \text{ fm}^{-1} \) and \( k_i \sim 0.2 \text{ fm}^{-1} \) and have a dip at \( p_{jk} \sim 0.7 \text{ fm}^{-1} \) and \( k_i \sim 0.7 \text{ fm}^{-1} \). The peak of \( \Delta n(p_{jk}) = n_r(p_{jk}) - n_{nr}(p_{jk}) \) and \( \Delta n(k_i) = n_r(k_i) - n_{nr}(k_i) \) has a shift to up for setting the permutation coefficient \( C \) to one, whereas by setting the Jacobian function \( N \) to one, it has a shift to down and by setting both Jacobian and permutation coefficient to one, the result is a small shift to down. The behavior for the dip is reversed.

**IV. SUMMARY AND OUTLOOK**

In this work we solved the relativistic momentum-space Faddeev equation for three nucleons interacting with a spinless Malfliet-Tjon type potential without partial-wave decomposition for the three-body binding energy and calculated the corresponding bound-state wave function. In order to identify relativistic effects the relativistic two-body interaction was defined so it gives in the two-body rest frame the same phase shifts and wave functions as the non-relativistic interaction. Relativistic effects arise since the interacting two-body subsystems are not at rest in the three-body rest frame. Lorentz boosts associated with each subsystem are used to transform the two-body interactions from the two-body rest frame to the three-body rest frame. This transformation is determined by both the relativistic symmetry and cluster properties.

The requirement that the relativistic and non-relativistic two-body interactions be phase equivalent is due to the fact that realistic non-relativistic nucleon-nucleon interactions are already designed to be consistent with experiment, and thus are consistent with special relativity. This means that all of the observable effects of special relativity are related to the different ways that the relativistic and non-relativistic problems treat the Fermi motion. The relativistic Faddeev equation is simply a reformulation of the eigenvalue problem for the relativistic mass operator. However, it has the important advantage that in the limit that the mass scales are large compared to the momentum scales, both the variables and the kernel of the integral equation approach the corresponding quantities that appear in the non-relativistic Faddeev equation. This relation is not as transparent when one compares the relativistic mass operator and the non-relativistic rest Hamiltonian. This also suggests that as long as the Fermi momentum scales are small compared to the mass scales relativistic corrections are expected to be small. Of course, this naive picture is impacted by exchange symmetry, and because the Malfliet-Tjon potential is a relatively hard potential, i.e. high momenta being involved, it needs to be verified by a calculation.

A comparison of the relativistic and non-relativistic equations show four essential differences. Two are related to the Jacobi momenta, which leads to different treatments of the permutation operator in the relativistic and non-relativistic Faddeev kernels. While these are choices of variables, the relativistic mass operator (13) has an S-matrix that clusters is naturally expressed in terms of the relativistic Jacobi momenta. The difference between these variables and the corresponding non-relativistic Jacobi momenta appear in the coefficients \( C \) defined in Eq. (29) and the non-trivial Jacobians (factors \( N \) of Eq. (25)) in the relativistic case. For \( C \to 1 \) and \( N \to 1 \) these become the non-relativistic Jacobi momenta. The combination of these two factors are associated with the kinematics of cluster properties. An important observation of our calculations is that those two quantities have opposite effects on the value of the binding energy, and that the combination of those to quantities is essential to have a net effect, which is about a factor of four to five smaller than each effect separately.

The other two areas where relativity plays a role is in the part of the Faddeev kernel involving the two-body transition operator and the free three-body Green’s functions. The difference between the relativistic and non-relativistic half-shell \( T \) is contained in the ratio \( F \), Eq. (17), which becomes 1 in the limit that the masses are much larger than the momentum scales. This is input to the kernel of the first resolvent equation so there are similar correction to the off shell transition matrix elements. The combination \( T(z)g_0(z) \) is dimensionless, in both the relativistic and non-relativistic case. Again, setting \( F \) to one without making a corresponding change in the free Green’s function
integral relation, which connects the transition operator at a given energy argument 

\[ \langle p \mid T \mid p \rangle = \int d^3p' \delta(p' - p) T(p, p'; z_i) \]

Choosing the vector shell momentum variables, i.e.

\[ T \]

Multiplying Eq. (A1) from the left and right by an interaction operator leads to a relatively small increase in the binding energy. Finally, we calculate that relativistic effects decrease the binding energy by about 3.3%. This is consistent with the results of the calculations of [21, 22].

This work demonstrates that direct integration techniques can be used to achieve the same results that can be obtained using partial-wave methods. Since our long-term interest is to first replace the Malfliet-Tjon interaction by a realistic interaction that has a more complicated spin-isospin dependence, and then to extend the calculations to treat scattering at the few GeV scale, it is important to test these methods in successive steps.

Appendix A: The Boosted Off-Shell T-matrix Obtained via Resolvents

1. Resolvent Equations

Starting from the resolvent of \( M, g(z_i) = (z_i - M)^{-1} \), where \( z_i = E_i + i \varepsilon \) one obtains the first resolvent equation that relates the resolvent at two different values of \( z_i \) as

\[
g(z_j) = g(z_i) + [g(z_j) - g(z_i)] = g(z_i) + g(z_j) [g^{-1}(z_i) - g^{-1}(z_j)] g(z_i).
\]  

(A1)

Multiplying Eq. (A1) from the left and right by an interaction operator \( V \) and adding \( V \) to both sides of the equation leads to

\[
V + V g(z_j) V = V + V g(z_j) V + V [g(z_j) - g(z_i)] V,
\]  

(A2)

or

\[
T(z_j) = T(z_i) + V g(z_j) [z_i - z_j] g(z_i) V
= T(z_i) + T(z_j) g_0(z_j) [z_i - z_j] g_0(z_i) T(z_i)
= T(z_i) + T(z_j) [g_0(z_j) - g_0(z_i)] T(z_i),
\]  

(A3)

where we used the identity \( \frac{1}{A} - \frac{1}{B} = \frac{1}{A(B - A)} \) for the definition of the transition operator \( T(z_i) = V + V g(z_i) V \) as well as the identity \( g(z_i) V = g_0(z_i) T(z_i) \), with \( g_0(z_i) = (z_i - M_0)^{-1} \) being the resolvent of \( M_0 \). We now obtain an integral relation, which connects the transition operator at a given energy argument \( z_i \) with the transition operator at a different energy \( z_j \).

Next, we take matrix elements, \( \langle p | T(z_i) | p' \rangle \equiv T(p, p' ; z_i) \). Since the relativistic T-matrix is only known for half-shell momentum variables, i.e. \( T(p, p_i ; z_i) \), we need to take the matrix elements of Eq. (A3), which leads to the inhomogeneous integral equation

\[
\langle p | T(z_j) | p_i \rangle = \langle p | T(z_i) | p_i \rangle + \int d^3p'' \delta(p' - p'') \langle p'' | g_0(z_j) - g_0(z_i) \rangle \langle p'' | T(z_i) | p_i \rangle.
\]  

(A4)

Here the inhomogeneous term is given by the half-shell T-matrix elements \( \langle p | T(z_i) | p_i \rangle = T(p, p_i ; z_i) \), and we solve for the off-shell matrix elements \( \langle p | T(z_j) | p_i \rangle = T(p, p_i ; z_j) \).

2. Numerical Realization

Writing Eq. (A4) explicitly using \( z_i \equiv E(p_i) \) leads to

\[
T(p, p_i ; E(p_j)) = T(p, p_i ; E(p_j)) + \int d^3p'' T(p, p'', E(p_j)) \left[ \frac{1}{E(p_j) - E(p'')} + i \varepsilon \right] \left[ \frac{1}{E(p_i) - E(p'')} + i \varepsilon \right] T(p'', p_i ; E(p_i)).
\]  

(A5)

Choosing the vector \( p \) parallel to the z-axis and the vector \( p_i \) in the x-z plane leads to the following angle variables

\[ \hat{p} \cdot \hat{p}_i \equiv x_i \]
\[ \hat{p}'' \cdot \hat{p}_i = \hat{x}_i = x_i x'' - \sqrt{1 - x_t^2} \sqrt{1 - x''^2} \cos \phi_{p'' p_i} = \hat{x}_i (x_i, x'', \cos \phi_{p'' p_i}) \]
\[ \hat{p} \cdot \hat{p}'' = x''. \]  

(A6)

Inserting the above variables into Eq. (A6) leads to
\[
T(p, p_i, x_i; E(p_j)) = T(p, p_i, x_i; E(p_j)) 
+ \int_0^\infty dp'' \int_{-1}^1 dx'' \frac{1}{E(p_j) - E(p''') + i \epsilon} \left[ \int_0^\infty dp'' T(p'', p_i, \hat{x}_i (x_i, x'', \cos \phi_{p'' p_i}); E(p_i)) \right].
\]

(A7)

Here we note that the \( \phi'' \) integration only affects one term in the integral equation and we can carry it out separately. For convenience let us define
\[
T(p'', p_i, x_i, x''; E(p_j)) = \int_0^{2\pi} d\phi'' T(p'', p_i, \hat{x}_i (x_i, x'', \cos \phi_{p'' p_i}); E(p_i)).
\]

(A8)

The structure of Eq. (A7) is identical to the two-body LS equation [29] and can be solved in a similar fashion. However, one needs to carefully look at its singularities. For the calculation of the relativistic three-body bound state equation, we need the off-shell \( T \)-matrix at negative energies \( E(p_j) \). Thus, the first propagator in Eq. (A7) is non-singular, and its numerical value always negative. However, the second propagator exhibits a singularity at \( E(p_j) = E(p''') \) for each fixed momentum \( p_i \). This singular point on the momentum grid can be numerically treated with a subtraction technique. In the actual calculation, we work on a momentum grid for \( p_i \), and we use the same momentum grid for the integration over \( p''' \). In this case, when setting up the matrix equation to solve Eq. (A7), the singular point is located on the diagonal of this matrix, and all terms resulting from the analytic treatment of the singularity must be located on the diagonal.

In order to calculate the off-shell boosted \( T \)-matrix \( T_{ki} (p_{jk}, p'_{jk}, x_{p'jk} ; M_t - m_{0i}(k_i)) \) which appears in the kernel of Faddeev integral equation from right-half-shell boosted \( T \)-matrix \( T_{ki} (p_{jk}, p'_{jk}, x_{p'jk} ; \sqrt{m_{0jk}(p_j k') + k_i^2}) \) we solve Eq. (A7) for \( E(p_j) = M_t - m_{0i}(k_i) \) and \( E(p_i) = \sqrt{m_{0jk}(p_j k') + k_i^2} \).

After calculating the singularity of the second integral of Eq. (A7) with the subtraction method, the explicit form of the first resolvent integral equation is obtained as
\[
T_{jk} (p_{jk}, p'_{jk}, x_{p'jk} ; M_t - m_{0i}(k_i)) = T_{jk} (p_{jk}, p'_{jk}, x_{p'jk} ; \sqrt{m_{0jk}(p_j k') + k_i^2}) 
+ \int_0^\infty dp'' \int_{-1}^1 dx'' \frac{1}{M_t - m_{0i}(k_i) - \sqrt{m_{0jk}(p''')^2 + k_i^2}} 
\times T_{jk} (p''_{jk}, p'_{jk}, x_{p'jk}, x_{p''jk} ; \sqrt{m_{0jk}(p'''}^2 + k_i^2} \left[ T_{jk} (p_{jk}, p''_{jk}, x_{p'jk}, x_{p''jk} ; M_t - m_{0i}(k_i)) ight] 
\left\{ \frac{1}{4} \int_0^\infty dp''_{jk} p''_{jk} \int_{-1}^1 dx''_{p''_{jk}} \frac{1}{\sqrt{m_{0jk}(p''_{jk})^2 + k_i^2} \left[ T_{jk} (p_{jk}, p''_{jk}, x_{p'jk}, x_{p''jk} ; M_t - m_{0i}(k_i)) \right] 
- \frac{1}{2} \int_0^\infty dp''_{jk} \int_{-1}^1 dx''_{p''_{jk}} \frac{1}{p''_{jk}^2} \sqrt{m_{0jk}(p''_{jk})^2 + k_i^2} \left[ T_{jk} (p_{jk}, p''_{jk}, x_{p'jk}, x_{p''jk} ; M_t - m_{0i}(k_i)) \right] 
- \frac{1}{4} \int_0^\infty dp''_{jk} \int_{-1}^1 dx''_{p''_{jk}} \frac{1}{p''_{jk}^2} \left[ T_{jk} (p_{jk}, p''_{jk}, x_{p'jk}, x_{p''jk} ; M_t - m_{0i}(k_i)) \right] 
- \frac{1}{4} \int_0^1 dx''_{p''_{jk}} p''_{jk} \sqrt{m_{0jk}(p''_{jk})^2 + k_i^2} \left( \frac{1}{\pi} \ln \frac{p''_{jk}^{\text{max}} + p'_j}{p''_{jk}^{\text{max}} - p'_{jk}} \right) \right\}. 
\]

The integral equation is solved for a given value of momentum \( k_i \), equal to boost momentum \( k_{jk} \), and for all values of left momentum \( p_{jk} \).
This work was performed under the auspices of the National Science Foundation under contract NSF-PHY-1005587 with Ohio University and NSF-PHY-1005501 with the University of Iowa. Partial support was also provided by the U. S. Department of Energy, Office of Science of Nuclear Physics, under contract No. DE-FG02-93ER40756 with Ohio University, and contract No. DE-FG02-86ER40286 with the University of Iowa. We thank the Ohio Supercomputer Center (OSC) for the use of their facilities under grant PHS206.

TABLE I. The relativistic (r) and non-relativistic (nr) [18] three-body binding energies calculated with the MT-V potential [5]. $E_{\text{approx}}$ indicates the relativistic three-body binding energies calculated for Jacobian function $N(k_i,k'_i,x_{k'_i}) = 1$, permutation coefficient $C(k'_i,k_i,x_{k'_i}) = 1$, the analytical term $F(p_{jk},p'_{jk},k) = 1$, and using the non-relativistic free propagator, as well as different combinations thereof.

|       | $E_{\text{approx}}$ [MeV] | $E_r$ [MeV] | $\frac{E_{\text{approx}} - E_r}{E_r}$ [%] |
|-------|---------------------------|-------------|------------------------------------------|
| $N = 1$ | $-7.4825$ | $-7.5412$ | $0.78$ |
| $C = 1$ | $-7.4825$ | $-7.3641$ | $0.02$ |
| $N = C = 1$ | $-7.4825$ | $-7.4934$ | $0.15$ |
| $F = 1$ | $-7.4825$ | $-7.6606$ | $2.38$ |
| $G_0$ | $-7.4825$ | $-7.3446$ | $1.84$ |
| $F = 1, G_0$ | $-7.4825$ | $-7.4993$ | $0.22$ |

FIG. 1. (Color online) The analytical term $F(p_{jk},p'_{jk},k)$ connecting the relativistic and non-relativistic right-half-shell $T$-matrices, Eq. (17), as function of the momenta $p_{jk}$ and $p'_{jk}$ in the two-body subsystem, for a fixed third particle momentum $k_i = 5 \text{fm}^{-1}$. 
FIG. 2. (Color online) The matrix elements of Jacobian function $N(k \cos(\theta), k \sin(\theta), x)$, Eq. (25), as function of the angles $x$ and $\theta$ calculated for different values of momentum $k$. 
FIG. 3. (Color online) The matrix elements of permutation coefficient $C(k \cos(\theta), k \sin(\theta), x)$, Eq. (29), as function of the angles $x$ and $\theta$ calculated for different values of momentum $k$. 
FIG. 4. (Color online) The magnitude of the relativistic three-body bound state wave function $\Psi(p_{jk}, k_i, x_{p_{jk}})$ as function of the pair momentum $p_{jk}$ and the spectator momentum $k_i$ for fixed values $x_{p_{jk}} = 0$ (a) and $x_{p_{jk}} = +1$ (b) obtained with the MT-V potential [5, 18]. The difference between relativistic and non-relativistic wave functions are shown for fixed values $x_{p_{jk}} = 0$ in panel (c) and $x_{p_{jk}} = +1$ in (d).
FIG. 5. (Color online) The relativistic and non-relativistic momentum distribution function $n(k_i)$ (solid and filled squares) and $n(p_{jk})$ (dashed and filled circles) obtained from the MT-V potential [5, 18]. The $n(p_{jk})$ are scaled with a factor 0.1.
FIG. 6. (Color online) The difference between the relativistic and non-relativistic momentum distribution functions (a) for $n(p_{jk})$ and (b) for $n(k_i)$ calculated from the MT-V potential (solid line). The dashed line shows the difference for the case when $C = 1$ in the relativistic calculation, while for the dash-dotted line $N = 1$. The filled circles represent a calculation in which both, $C = N = 1$.
