Room temperature spin valve effect in NiFe/WS\textsubscript{2}/Co junctions

Muhammad Zahir Iqbal\textsuperscript{1,2}, Muhammad Waqas Iqbal\textsuperscript{3}, Salma Siddique\textsuperscript{4}, Muhammad Farooq Khan\textsuperscript{5} & Shahid Mahmood Ramay\textsuperscript{6}

The two-dimensional (2D) layered electronic materials of transition metal dichalcogenides (TMDCs) have been recently proposed as an emerging candidate for spintronic applications. Here, we report the exfoliated single layer WS\textsubscript{2}-intalayer based spin valve effect in NiFe/WS\textsubscript{2}/Co junction from room temperature to 4.2 K. The ratio of relative magnetoresistance in spin valve effect increases from 0.18\% at room temperature to 0.47\% at 4.2 K. We observed that the junction resistance decreases monotonically as temperature is lowered. These results revealed that semiconducting WS\textsubscript{2} thin film works as a metallic conducting interlayer between NiFe and Co electrodes.

Two-dimensional (2D) nanomaterials have been already established to have prodigious potential for application in the field of spintronics\textsuperscript{1–9}. The 2D transition-metal dichalcogenides (TMDCs) have attractive properties such as bandgap, atomically thin layered structure and a promising material for active channel in field-effect transistor applications. In particular, tungsten- and molybdenum-based TMDC are attracting materials due to semiconducting and optoelectronics properties\textsuperscript{10–12}. The tungsten disulfide (WS\textsubscript{2}) has a fascinating property that it shows direct bandgap for monolayer while have indirect bandgap for bulk. The bulk WS\textsubscript{2} have an indirect bandgap (1.4 eV) but goes to a direct bandgap (2.1 eV) material when exfoliated into the monolayer\textsuperscript{13}. The structure of single layer of WS\textsubscript{2} crystals is formed by covalently bonded in-plane S-W-S atoms, which contain of two sheets of S atoms and one sheet of W atoms and are hexagonally packed. In general wide band gap oxides such as Al\textsubscript{2}O\textsubscript{3}\textsuperscript{14–16} or MgO are previously being utilized as a nonmagnetic spacer in spin valve devices\textsuperscript{17–21}. The basic principal of spin valve comprises of two ferromagnetic metal layers decoupled by a non-magnetic insertion, which permits parallel and antiparallel alignment of the magnetizations of two magnetic layers. The magnetoresistance of a spin valve can be determined from the magnetization alignment configuration between two ferromagnetic electrodes and controlled by the external magnetic field. Recently, there has been extensive interest in the spin-dependent properties of 2D materials such as: graphene, hexagonal boron nitride, molybdenum disulfide and it became more incorporating platform for non-magnetic interlayer spacer between two ferromagnetic electrodes in current perpendicular to plane spin valve device structures\textsuperscript{1,6,7}. There have been efforts to explore a variety of new spin valve structures of 2D materials with single interlayer spacer to few layers\textsuperscript{1–9}, and further continue to be fully investigated for new materials.

Here, we report on the first fabrication and characterization of tungsten disulfide based spin valve effect in the junction comprising top electrode (Co) and bottom electrode of Permalloy (Py, Ni\textsubscript{81}Fe\textsubscript{19}) film and WS\textsubscript{2} as an interlayer. The magnetoresistance show two resistance states depending on the magnetization alignment configuration between two electrodes. The spin valve signals are observed from room temperature to 4.2 K and having magnetoresistance ratios of 0.18\% at 300 K to 0.47\% at 4.2 K. We have also studied the basic functionality of semiconducting WS\textsubscript{2} film junction resistance as function of temperature.

Results and Discussion

Characterization of WS\textsubscript{2} spin valve. Figure 1(a) shows a schematic of WS\textsubscript{2} spin valve consisting of top Co electrode, bottom NiFe electrode and a WS\textsubscript{2} interlayer. The device structure and the measurement configuration are shown in Fig. 1(b). While current flows from Co to NiFe through WS\textsubscript{2} interface, voltage is measured between Co and NiFe. The in-plane magnetic field (H) was applied at 45° to the direction of the ferromagnetic (FM)
electrodes. Therefore the magnetization alignments can be made semi-parallel or semi-antiparallel by sweeping \( H \). The optical micrograph of the complete device is portrayed in Fig. 1(c).

Figure 2(a) shows Raman spectrum measured for the WS\(_2\) film. Raman spectra of the SL-WS\(_2\), film show strong signals of in-plane \( E_{2g}^1 \), out-of-plane \( A_{1g} \), and vibration second-order 2LA(M) modes. The first-order \( E_{2g}^1 \) and \( A_{1g} \) optical modes were used to identify the 2D materials, such as MoS\(_2\), but the intensity of the 2LA(M) mode at 352 cm\(^{-1}\) was considerably higher for WS\(_2\). The Raman peak positions of \( E_{2g}^1 \) and \( A_{1g} \) for SL-WS\(_2\) are 355.2 and 417.7 cm\(^{-1}\) respectively. The frequency difference between Raman \( A_{1g} \) and \( E_{2g}^1 \) modes (\( \Delta = A_{1g} - E_{2g}^1 \)) is about
which indicates a single layer of the WS2 film. However, the 2LA(M) mode was overlapped with the first-order mode at 355.2 cm$^{-1}$. Lorentzian peaks fitting clarify the contribution of each peak as shown in Fig. 2(b).

**Spin valve effect and current-voltage characteristics in WS$_2$-interlayer junction.** The spin valve effect was studied by examining the relative magnetoresistance ratio (MR), which is defined by $MR = [R_{AP} - R_P] / R_P$. Here, $R_{AP}$ is the magnetic field dependent resistance and $R_P$ is the resistance corresponding to the parallel alignment of magnetizations. Figure 3 (a) shows MR signal of NiFe/SL-WS$_2$/Co spin valve device. The value of MR shows bistable states where high (low) resistance appears in the antiparallel (parallel) magnetization configuration between Co and NiFe. The magnitude of MR value is observed of the order of 0.18% at 300 K and 0.47% at 4.2 K. We have further investigated the nature of NiFe/SL-WS$_2$/Co junction by measuring current-voltage ($I$–$V$) characteristics. The $I$–$V$ curves of the junctions at various temperatures range from 4.2 K to 300 K are shown in Fig. 3(b). The linear behavior of $I$–$V$ curves indicate the ohmic characteristics of the junctions.

**Temperature dependence of the spin valve effect.** The WS$_2$-interlayer spin valve device reveals a sequence of MR curves at various temperatures ranging from 300 K to 4.2 K as shown in Fig. 4(a). The magnitude of the spin valve signal having MR monotonically decreases as the temperature is increased. The decrease of MR at higher temperature can be attributed to many possible origins such as magnetic impurity scattering, surface states, and thermal smearing of the electron energy distribution in ferromagnetic. The similar temperature dependence has been observed in magnetic tunnel junction. The switching points of MR curves becomes broader at low temperature due to increasing switching fields of FM as thermal agitation is weakened. The trend of increment in the MR values as a function of temperature is shown in Fig. 4(b).

**Current bias dependence of the spin valve effect.** The magnetoresistance variation is examined by applying various bias current on the junction. Figure 5 (a) shows the spin valve effect at different bias currents from 10 µA to 50 µA. The results reveal that by increasing bias current the magnetoresistance is decreased. The trend of change in magnetoresistance as a function of bias current is shown in Fig. 5(b). The decrease of magnetoresistance by increasing bias current is attributed to the localized trap states in the interlayer.

**Conclusions**

In conclusion, we have demonstrated spin valve effect in single layer WS$_2$ film as an intervened layer between NiFe and Co electrodes. Our results show that the spin valve effect of WS$_2$ junction have relative magnetoresistance in spin valve effect increases from 0.18% at room temperature to 0.47% at 4.2 K. We observed that junction resistance decreases monotonically by reducing the temperature. These results revealed that semiconducting WS$_2$ thin film works as a metallic conducting interlayer between NiFe and Co electrodes. The WS$_2$ interlayer spin...

Experimental Section

Material and device fabrication. The single layer WS2 film was obtained by mechanically exfoliating natural WS2 using adhesive tape and then the flake was transferred onto the pre-patterned Py electrodes on SiO2/Si substrate using wet transfer method. The single layer (SL) was initially identified by optical microscopy and then further confirmed by Raman spectroscopy. The device fabrication is categorized into three different parts; bottom Py film, WS2 film transfer, and top Co film. Before that the outer patterns were made on Si substrate with SiO2 thickness of 300 nm using photo-lithography and Cr/Au (5/30 nm) deposition. The bottom Py electrodes were initially patterned using e-beam lithography. A standard lift-off procedure was used to obtain the bottom electrode lines after evaporating Py with thickness of 55 nm. Then a single layer WS2 was transferred on top of bottom Py electrodes. In the subsequent process top Co electrode with thickness of 75 nm was patterned by using e-beam lithography and lift-off process. The width of both top and bottom electrodes were 3 μm.

Device characterization and measurement setup. Renishaw Raman micro-spectrometer was used to characterize the WS2 samples. The laser wavelength of the spectrometer was 514 nm, and the power was kept below 1.0 mW to avoid laser-induced heating. The transport measurements for WS2 based spin valve devices were performed using ac lock-in technique. The bias currents was kept 10 μA for temperature dependent spin transport measurements and further increased up to 50 μA to study the effect of bias dependence. The devices were cooled by liquid helium for low temperature measurements and the temperature was modulated by Lake Shore 331 temperature controller.
