Activated c-Kit receptor in the heart promotes cardiac repair and regeneration after injury

The role of endogenous c-Kit receptor activation on cardiac cell homeostasis and repair remains largely unexplored. Transgenic mice carrying an activating point mutation (TgD814Y) in the kinase domain of the c-Kit gene were generated. c-KitTgD814Y receptor was expressed in the heart during embryonic development and postnatal life, in a similar timing and expression pattern to that of the endogenous gene, but not in the hematopoietic compartment allowing the study of a cardiac-specific phenotype. c-KitTgD814Y mutation produced a constitutive active c-Kit receptor in cardiac tissue and cells from transgenic mice as demonstrated by the increased phosphorylation of ERK1/2 and AKT, which are the main downstream molecular effectors of c-Kit receptor signaling. In adult transgenic hearts, cardiac morphology, size and total c-Kit+ cardiac cell number was not different compared with wt mice. However, when c-KitTgD814Y mice were subjected to transmural necrotic heart damage by cryoinjury (CI), all transgenic survived, compared with half of wt mice. In the sub-acute phase after CI, transgenic and wt mice showed similar heart damage. However, 9 days after CI, transgenic mice exhibited an increased number of c-Kit+CD31+ endothelial progenitor cells surrounding the necrotic area. At later follow-up, a consistent reduction of fibrotic area, increased capillary density and increased cardiomyocyte replenishment rate (as established by BrdU incorporation) were observed in transgenic compared with wt mice. Consistently, CD45− c-Kit+ cardiac stem cells isolated from transgenic c-KitTgD814Y mice showed an enhanced endothelial and cardiomyocyte differentiation potential compared with cells isolated from the wt. Constitutive activation of c-Kit receptor in mice is associated with an increased cardiac myogenic and vasculogenic reparative potential after injury, with a significant improvement of survival.

Cell Death and Disease (2016) 7, e2317; doi:10.1038/cddis.2016.205; published online 28 July 2016

c-Kit is a tyrosine kinase receptor essential for proliferation, survival and migration of several stem cell types such as melanocyte precursors, hematopoietic and germ stem cells.1–4 More recently, c-Kit receptor was reported to be expressed in cardiac and neuronal stem cells.5,6 Mice lacking c-Kit gene present germ cell and melanocyte defects and die in the first days of postnatal life because of impaired hematopoiesis.7,8 The binding of c-Kit ligand (KL) induces receptor homodimerization and autophosphorylation of the intracellular tyrosine kinase domains leading to the modulation of different signaling pathways such as AKT and MAPKs.9–11

In the past 15 years, several studies have shown that c-Kit+ cardiac stem cells (CSCs) have beneficial effects in cardiac repair and regeneration.12 Genetically mutant mice deficient in c-Kit signaling (W/Wv) show a worsened cardiac remodeling after myocardial infarction, conversely transgenic mice over-expressing KL in the heart exhibit an improved myocardial repair compared with their wt littermates after myocardial infarction.13–15 Increased expression of KL occurring in ischemic heart favors migration of c-Kit+ bone marrow-derived and CSCs via activation of p38 MAPK.16–18 Furthermore, c-Kit+ CSCs have been recently used in the treatment of patients with ischemic cardiomyopathy and heart failure with significant improvement in systolic function and a reduction in infarct size.19–21

Although c-Kit is widely used as a 'cell surface marker' to identify stem cells from the embryonic as well as adult heart,22,23 little information14,15 is available on the function that c-Kit signaling has in the activation of CSCs in cardiac repair.

To investigate the role of c-Kit in heart repair, transgenic mice were generated carrying a mutated version of c-Kit gene. The substitution of tyrosine for aspartic acid 814 in the phosphotransferase domain leads to constitutive activation of the receptor. Decreased fibrotic area in cryoinjured
hearts, reduced inflammatory myeloid cells in the blood, increased number of c-Kit\(^*\)CD31\(^*\) endothelial cells and isoelectin B4 (IB-4)-labeled capillaries as well as BrdU-positive newly formed cardiomyocytes in damaged cardiac area of transgenic mice were observed. MAPK and AKT activation was significantly enhanced in the hearts and CSCs of transgenic mice, whereby the two kinases modulate the activation and endothelial/myogenic differentiation of CSCs. Overall, these data indicate that the activated c-Kit receptor exerts a beneficial protective/regenerative role for myocardial tissue after injury improving cardiac remodeling and repair while fostering differentiation of cardiac progenitor cells likely due to MAPK and AKT signaling activation.

Results

Generation of transgenic mice expressing an activated c-Kit receptor in heart. To generate transgenic mice expressing a constitutively activated c-Kit receptor, a bacterial artificial chromosome (BAC) reconstitution method was used allowing the transcription of c-Kit gene by endogenous regulatory sequences (Figure 1).

In humans, the 816 aspartic amino acid of the second kinase domain of c-Kit was found to be substituted with activating mutations in several tumors (Figure 1a).\(^{24-26}\) The corresponding murine 814 aspartic residue was therefore successfully mutated to tyrosine (D814Y) in the mouse BAC (RP23-309C11) as confirmed by sequence analysis (Figures 1a, b). The resulting BAC was subsequently used to generate transgenic mice. Several founder lines were produced, two of which (Tg7 and Tg8) transmitted and similarly expressed the constitutive active c-Kit receptor (c-Kit\(^{TgD814Y}\)).

Transgenic mice were crossed with c-Kit wild-type (c-Kit\(^{+/+}\)) or c-Kit heterozygous (c-Kit\(^{+/-}\)) mice. In embryonal (Figure 1c) and neonatal (Figure 1d and Figure 2b) hearts of transgenic mice expressed the receptor 2.5-fold higher when compared with control mice, indicating that c-Kit\(^{TgD814Y}\) protein expression was similar to receptor endogenous levels of c-Kit\(^{+/+}\) mice. At 1 week of age, c-Kit receptor could be readily detected by western blotting (WB) analysis on total heart lysates from c-Kit\(^{TgD814Y}\)\(-/-\) mice, but not from c-Kit\(^{-/-}\) mice in which it was detected only by immunoprecipitation (Figure 1e, Supplementary Figure 1A). To verify whether the introduction of the D814Y mutation induced the activation of c-Kit receptor, a pan antibody against phospho-tyrosine was used in WB analyses, allowing the detection of all putative receptor autophosphorylation sites. Figures 1d and e show an increased tyrosine phosphorylation in a protein band correspon ding to c-Kit receptor in transgenic hearts compared with heterozygous hearts. These results were confirmed in hearts of c-Kit\(^{TgD814Y}\)\(-/-\) mice (Figure 2c and data not shown).

To further characterize the transgene expression, isolated fetal and neonatal cardiac cells from c-Kit\(^{TgD814Y}\)\(-/-\) mice were obtained and cultured for 24 h before immunofluorescence staining. Figure 1f shows that c-Kit is expressed in myocyte progenitors as revealed by the co-staining with MEF2C marker (Figure 1f, upper panels) but not in terminally differentiated myocytes as shown by MF20 staining (Figure 1f, lower panels). These results show that the expression of the constitutively activated receptor did not prevent normal myocyte differentiation and did not induce ectopic expression of c-Kit in differentiated myocytes. Transgenic protein expression and activation were also observed in testis and cerebellum at different ages (Supplementary Figure 1B). These data confirm that transcription of c-Kit gene, with BAC reconstitution method, occurred under endogenous regulatory mechanisms in these cell types.

Activated c-Kit\(^{TgD814Y}\) receptor is not expressed in hematopoietic compartments. c-Kit knockout mice die after birth because of severe impairment of hematopoiesis. The mutated and constitutively active c-Kit receptor protein was not detected in adult bone marrow by WB and flow cytometry analyses (Supplementary Figures 1C and D). This might reflect the reported absence of expression of the BAC construct within the bone marrow hematopoietic cells.\(^{27}\)

In order to extensively study the expression of c-Kit\(^{TgD814Y}\) transgene in hematopoietic compartments, we generated c-Kit-deficient mice (c-Kit\(^{-/-}\); Supplementary Figure 1E) and we reconstituted them with the transgene (c-Kit\(^{TgD814Y}\)\(-/-\)). Similarly to c-Kit\(^{-/-}\) embryos and newborns, c-Kit\(^{TgD814Y}\)\(-/-\) pups were extremely anemic, smaller than their littermates and all died before birth (Supplementary Figure 1E), indicating that the transgene does not rescue the lethal phenotype of c-Kit knockout mice. The lethality of c-Kit\(^{TgD814Y}\)\(-/-\) mice was caused by the lack of transgene expression in fetal liver. A marginal c-Kit expression, insufficient to rescue the phenotype, was observed in both c-Kit\(^{-/-}\) and c-Kit\(^{TgD814Y}\)\(-/-\) c-Kit\(^{-/-}\) livers from E15.5 probably owing to the strategy used for c-Kit\(^{-/-}\) mouse generation (Supplementary Figures 1F and G and methods section). On the contrary, immunofluorescence analyses revealed c-Kit transgene expression in embryonic c-Kit\(^{TgD814Y}\)\(-/-\) cardiac tissue, whereas, as expected, no expression was observed in any of the c-Kit\(^{-/-}\) embryos (Supplementary Figure 1F). Transgene c-Kit expression in the heart other than in head, branchial arch and stomach was also observed at earlier time of development.

Figure 1  
D814Y substitution induces a constitutive c-Kit activation. (a) Pairwise local alignments of human (Homo sapiens) and mouse (Mus musculus) c-Kit protein sequences surrounding the putative residue for constitutive activation in the second kinase domain of the receptor. (b) Sequence chromatogram showing the aspartic acid to tyrosine mutation introduced in c-Kit mouse BAC RP23-309C11. (c) WB and densitometry of c-Kit expression on hearts collected from embryos at different stages of development. Mutant c-Kit protein is expressed 2.5-fold higher than endogenous level in c-Kit\(^{TgD814Y}\)\(-/-\) embryos. (d) WB and densitometry of c-Kit expression on total heart lysate collected from neonatal mice. Mutant c-Kit protein is expressed 2.5-fold higher than endogenous c-Kit protein levels in c-Kit\(^{TgD814Y}\)\(-/-\) mice. c-Kit activation is shown by a pan phospho-tyrosine antibody that recognizes a specific band at the receptor height. (e) WB analysis on hearts collected from 7 dpp mice. Data are obtained from at least three separate hearts and reported ± S.D.; **P<0.01, ***P<0.001. (f) Immunofluorescence analysis of c-Kit\(^{+}\) cells (red) in isolated c-Kit\(^{TgD814Y}\)\(-/-\) neonatal myocytes cultured for 24 h co-stained with MEF2C (green) and MF20 (green). Nuclei (blue) were counterstained with Hoechst 33342. Scale bars 30 μm.
These observations extend the knowledge of c-Kit expression to early heart development and also point out the important notion that c-Kit transgene is expressed in the heart but not in fetal and adult hemopoietic tissues. Thus, this transgenic mouse model offers a unique advantage over the previous mouse models, as it does exclude that any cardiac phenotype is secondary to activated c-Kit receptor within bone marrow cells.
Figure 2  MAPK and AKT activation in c-KitTgD814Y transgenic hearts. (a) Hearts and livers from c-KitTgD814Y c-Kit−/− and c-Kit−/− E15.5 were isolated and protein extracts analyzed for AKT and MAPK phosphorylation. Phosphorylated substrates were increased in embryonic hearts from transgenic mice. (b) WB analysis on protein extracts from c-KitTgD814Y c-Kit+/+ and c-Kit−/+ 3 dpp hearts of two different animals. Densitometry of c-Kit expression, MAPK and AKT phosphorylation is reported. Data are reported as mean of three hearts ± S.D.; * P<0.05, ** P<0.01, *** P<0.001. (c) Neonatal cardiac cells isolated from c-KitTgD814Y c-Kit+/+ and c-Kit−/+ 3 dpp hearts were stimulated with 100 ng/ml of KL for 10 min and protein extracts processed for AKT and MAPK phosphorylation. Densitometry of six separate experiments is reported. Data are reported ± S.D.; * P<0.05, ** P<0.01
Activated c-Kit receptor induces ERK1/2 and AKT phosphorylation. c-Kit receptor downstream signaling mainly involves MAPK and PI3K pathways. In order to evaluate whether these pathways were activated in c-Kit<sup>TgD814Y</sup> mice, E15.5 c-Kit<sup>TgD814Y/c-Kit<sup>−/−</sup></sup> and c-Kit<sup>−/−</sup> whole liver and heart protein extracts were assessed for ERK1/2 and AKT phosphorylation (Figure 2a). No different phosphorylation levels of ERK1/2 and AKT were observed in liver extracts from c-Kit<sup>TgD814Y/c-Kit<sup>−/−</sup></sup> compared with knockout mice (Figure 2a) as expected from the absence of the transgene expression in the liver (Supplementary Figure 1F). Conversely, in cardiac samples of c-Kit<sup>TgD814Y/c-Kit<sup>−/−</sup></sup>, a small but significant increase in AKT phosphorylation and a strong increase in ERK1/2 phosphorylation were observed compared with c-Kit<sup>−/−</sup> mice (Figure 2a). Similar increases of ERK1/2 and AKT phosphorylation were observed in total heart lysates from 3 dpp c-Kit<sup>TgD814Y/c-Kit<sup>−/−</sup></sup> mice compared with c-Kit<sup>−/−</sup> mice (Figure 2b). In addition, the higher phosphorylation of ERK1/2 and AKT was also observed in transgenic c-Kit<sup>TgD814Y/c-Kit<sup>−/−</sup></sup> compared with c-Kit<sup>−/−</sup> freshly isolated neonatal cardiac cell preparations (Figure 2c).

Interestingly, the activation of c-Kit by its endogenous ligand (KL) induces ERK1/2 and AKT phosphorylation in cells isolated from wt hearts up to the level detected in cells from transgenic animals (Figure 2c). Furthermore, KL was not able to increase any activation of c-Kit receptor expression does not affect cardiac development and morphology. To evaluate the effects of c-Kit receptor activation on cardiac tissue and structure, we first established whether c-Kit constitutive activation affected the number of total cardiac c-Kit<sup>+</sup> cells in c-Kit<sup>TgD814Y</sup> mutant mice. To simplify the read-out of quantitative immunohistochemistry and FACS analysis, we crossed c-Kit<sup>TgD814Y</sup> mutant mice with transgenic mice expressing EGFP under the regulatory sequences of c-Kit promoter (pKit<sup>EGFP</sup>). In c-Kit<sup>TgD814Y/pKit<sup>EGFP</sup></sup> double transgenic hearts, the majority (over 95%) of c-Kit-expressing cells identified by the staining with an anti-c-Kit antibody co-expressed EGFP protein (Figure 3a). Histological analysis of cardiac section from mice at 1 dpp, 10 dpp and 2 months showed that c-Kit<sup>EGFP<sup>+</sup></sup> cells were distributed along the epicardium, spread into the myocardium and less frequently clustered in the endocardium. Importantly, the number of EGFP<sup>+</sup> cells was comparable in c-Kit<sup>TgD814Y/pKit<sup>EGFP</sup></sup> hearts and pKit<sup>EGFP</sup> at all time points (Figure 3b). Furthermore, myocardial capillary density and myocyte sizes were similar among c-Kit<sup>TgD814Y/pKit<sup>EGFP</sup></sup> and pKit<sup>EGFP</sup> hearts (data not shown). Thus, these data show that constitutive activated c-Kit receptor does not change total c-Kit<sup>+</sup> cell number, myocardial vascularization and myocyte growth during development and adult cell homeostasis, at least at the age we investigated.

Activated c-Kit receptor expression improves cardiac repair after injury. To challenge the role of activated c-Kit receptor expression for cardiac repair, ventricular damage was induced by cryoinjury (CI) in hearts of 2-month-old transgenic and wt mice (Figure 4). Animal survival, systemic inflammation and cardiac tissue remodeling were evaluated to assess the recovery after cardiac injury.

As shown in Figure 4a, 43% of c-Kit<sup>+/−</sup> mice died within 5 days after the injury, whereas c-Kit<sup>TgD814Y/c-Kit<sup>+/−</sup></sup> mice were resistant to the insult as no mice died after surgery. This result indicates that transgenic mice were protected from the acute damage. Blood samples were collected 1 week before heart injury and 1, 2 and 4 weeks after the damage to monitor the level of circulating inflammatory cells. The relative amounts of CD11b<sup>Gr1<sup>+</sup></sup> and CD11b<sup>Gr1<sup>−</sup></sup> myeloid cells were analyzed by flow cytometry (Figures 4b–e). These two myeloid cell subsets have been considered as indicators of tissues inflammation and remodeling, respectively. Figures 4c–e show pro-inflammatory CD11b<sup>Gr1<sup>+</sup></sup> cells increasing in both wt and transgenic mice 1 week after damage. After 2 weeks, the percentage of CD11b<sup>Gr1<sup>+</sup></sup> cells decreased to the baseline value detected before the damage in transgenic mice, whereas their percentage remained high in wt mice (Figures 4c and d). CD11b<sup>Gr1<sup>−</sup></sup> cell percentage dropped immediately after CI in both treated type of animals but only in transgenic mice returned to the basal level within 2 weeks (Figures 4c and e). These data demonstrate that CD11b<sup>Gr1<sup>+</sup></sup> and CD11b<sup>Gr1<sup>−</sup></sup> cells are differentially regulated in transgenic mice compared with wt animals after heart injury. These data also suggest that the relative percentage of circulating CD11b<sup>Gr1<sup>+</sup></sup> and CD11b<sup>Gr1<sup>−</sup></sup> in the blood parallel the increased survival of transgenic mice compared with wt.

To directly assess the damage determined by CI, the extent of fibrotic area was measured by Masson Trichromic staining 3, 9 and 30 days after damage (Figures 4f and g and Supplementary Figure 3A and B). While 3 days after damage, no fibrotic tissue was observed (data not shown), 9 days after damage a large Masson Trichromic-stained myocardial area was found in both wt and transgenic mice (Supplementary Figures 3A and B). At this time, a similar level of ventricular cell wall apoptosis was found in both wt and transgenic mice (Supplementary Figure 3C). However, 30 days after damage, the fibrotic area was threefold smaller in transgenic mice compared with wt animals (12.83 ± 4% versus 4.39% ± 2.44%) (Figures 4f and g and Supplementary Figure 3D). Concurrently, at 30 days after damage, cardiomyocyte size in...
the border zone of transgenic mice were smaller when compared with wild-type mice (Supplementary Figure 3E). These results suggest that mice carrying a constitutively activated c-Kit receptor have an advantage both in the acute response to myocardial injury as shown by an increased survival, as well as in the long term as shown by a more efficient repair of necrotic tissue.

Activated c-Kit receptor expression enhances endothelial and cardiomyocyte regeneration after injury in vivo. In order to clarify the cellular mechanism by which the transgene expression promotes cardiac repair, we investigated the growth and differentiation of c-KitTgD814Y-expressing cells after CI. Immunofluorescence analysis was performed to identify total cardiac c-Kit+ cells internal to the injured area 9 days after injury (Figure 5a). At this time point, c-Kit+ cell number that showed an evident elongated shape, was higher in transgenic mice compared with wt mice (Figure 5b; 72 ± 11 cells/mm² and 55 ± 7 cells/mm²). To verify the vascular lineage commitment rate of total c-Kit+ cells, we assessed the expression of c-Kit together with endothelial (CD31) and α-smooth muscle actin lineage markers within the damaged area. c-Kit+ cells were practically negative for smooth muscle actin in both genotypes, whereas more than 90% of c-Kit+ cells co-stained with CD31 in c-KitTgD814Y mice compared with ~60% in wt mice (Figures 5c and d). Consequently, at 30 days after CI, an increased capillary density was observed in transgenic mice compared with wt mice in peri-damaged area (Figure 5e). Finally, transgenic and wt mice were implanted with mini-osmotic pumps to systemically release BrdU immediately after injury for 28 days, in order to follow myocardial cell regeneration. A threefold increase of newly, mono-nucleated-formed BrdU+ cardiomyocytes was observed in transgenic hearts when compared with wt mice at 1 month after myocardial necrosis by CI (Figure 5f). Altogether, these data suggest that, in vivo, constitutive c-Kit receptor activation in myocardial cells fosters cardiac repair increasing angiogenic and myogenic response to injury.

c-Kit receptor activation increases CSC activation and differentiation in vitro. The data shown above cannot unequivocally establish a direct precursor-to-differentiated cell product relationship between committed c-Kit+ cells and the increased formation of endothelial cells and cardiomyocytes in transgenic mice after injury. Thus, to directly test this hypothesis, we isolated CD45−c-Kit+ CSCs35 from adult c-KitTgD814Y transgenic and wt mice (Figure 6a). When plated in LIF-conditioned CSC medium, transgenic c-KitTgD814Y cells showed an increased cell growth when compared with wt CSCs as demonstrated by their growth kinetic curve and BrdU incorporation rate in vitro (Figures 6b and c). This higher growth potential was correlated with an increased
Clonogenic potential established by single-cell deposition (Figure 6d). Furthermore, constitutive c-Kit receptor activation promoted CSC sphere formation, an in vitro marker of multipotent cells, when compared with wt CSCs (Figure 6e). These cellular characteristics of c-Kit TgD814Y CSCs were associated with c-Kit receptor activation as demonstrated by an increased ERK1/2 and AKT phosphorylation in transgenic versus wt CSCs (Figure 6f). Indeed, AKT inhibition by MK2206, a known selective allosteric inhibitor of AKT, and ERK1/2 inhibition by PD98059, a small molecule selectively targeting ERK1/2, were both able to reduce clonogenesis and spherogenesis rate in transgenic c-Kit TgD814Y CSCs (Figures 6g and h).
When cells were primed in LIF-deprived low-serum (2%) cardiomyogenic condition, CSCs from c-Kit\textsuperscript{TgD814Y} mice show an increased myogenic specification when compared with wt CSCs. Indeed, an increased number of mRNAs transcripts for Nkx2.5, known cardiomyocyte transcription factor and for Myh7, Actc1 and Tnn3, main contractile genes were detected in c-Kit\textsuperscript{TgD814Y} compared with wt CSCs (Figure 7a). Both MK2206 and PD98059 treatment significantly affected cell viability in low-serum myogenic differentiation conditions, preventing myogenic specification with negligible upregulation of the above cardiac transcription and contractile gene mRNAs (data not shown).

On the other hand, when CSCs were plated in specific LIF-deprived endothelial differentiation medium, a significant increase of CD31 and VEGFR2 endothelial RNA transcripts was observed in c-Kit\textsuperscript{TgD814Y} compared with c-Kit\textsuperscript{+/+} CSCs already at 3 days in differentiating medium, which was followed at 10 days by a higher number of CD31\textsuperscript{+} endothelial differentiated cells (Figure 7b and Supplementary Figure 4A). Interestingly, endothelial differentiation was abrogated by incubation with MAPK inhibitor (UO), but not with AKT inhibitor (LY) (Figure 7c and Supplementary Figure 4B), suggesting that MAPK is necessary for c-Kit-stimulated endothelial lineage differentiation.

Overall these data show that, in vitro, c-Kit receptor constitutive activation exerts several beneficial effects on CSCs enhancing their amplification, when primed to proliferate, and promoting their cardiomyocyte and endothelial differentiation, when coaxed to specific cardiac cell commitment.

**Discussion**

In the present study, a new mouse model was generated expressing c-Kit receptor with an activating amino acidic substitution to study the expression and activation of the receptor in cardiac development and its role during regenerative processes. The transgenic mice were generated mutating a BAC vector containing endogenous regulatory sequences of 67 Kb upstream the starting codon and 58 Kb downstream the stop codon. As previously described for other transgenic mice generated with vectors spanning similar regions of the c-Kit locus,\textsuperscript{27,36} transgene expression was not detected in fetal liver and adult bone marrow, probably owing to the lack of enhancer regions in the regulative sequence of the BAC,\textsuperscript{27} but its expression and activation was increased up to twofold compared with wt in heart other than in cerebellum because it is able to induce a focal, transmural and reproducing effect of heart.

Wild-type c-Kit\textsuperscript{+} cells respond to c-Kit cognate ligand by increasing ERK1/2 and AKT phosphorylation.\textsuperscript{38,39} We interestingly found a consistent increase of ERK1/2 and AKT phosphorylation levels in hearts and isolated cardiac cell preparations obtained at different ages of transgenic mice. This level of activation, specific to the activating gene mutation and confirmed by protein analysis of c-Kit\textsuperscript{TgD814Y} mice, was not further stimulated by treating the cells with the specific c-Kit ligand.

Altogether, these results support and strongly confirm that ERK1/2 and AKT are among the major targets of c-Kit receptor in cardiac c-Kit\textsuperscript{+} cells. Indeed, the substitution of the aspartic acid 814 with tyrosine was able to recapitulate the activation of PI3K and MAPK pathways naturally occurring following KL stimulation of the wt receptor, thus allowing to investigate the physiological role of c-Kit receptor in the heart. The 814 Aspartic mutation was previously found in different type of tumors and it was reported to induce a constitutive activation of c-Kit.\textsuperscript{24–26} Notably, transgenic mice carrying c-Kit\textsuperscript{TgD814Y} mutation were monitored for more than 2 years and no tumors such as GIST, seminoma or mastocytosis were detected.

A fully characterization of c-Kit\textsuperscript{TgD814Y} expression in the heart was performed by WB and immunohistochemistry showing that the activated receptor is expressed during embryogenesis, neonatal and adult life. BAC vectors, preserving endogenous gene regulation, gave the opportunity to study cardiac c-Kit\textsuperscript{+} cells in respect of their putative origin from the first heart field, proepicardium or epithelial to mesenchymal transition. Further characterization is required to verify if the two subpopulations expressing low and high c-Kit levels, recently described,\textsuperscript{40–43} are differently regulated in hearts of c-Kit\textsuperscript{TgD814Y} mice. By crossing the c-Kit\textsuperscript{TgD814Y} mice to pKit\textsuperscript{EGFP} mice, we concluded that number and localization of c-Kit\textsuperscript{+}EGFP\textsuperscript{+} double positive cells were similar between pKit\textsuperscript{EGFP} and c-Kit\textsuperscript{TgD814Y}pKit\textsuperscript{EGFP} hearts indicating a similar behavior of wt and transgenic cells in the intact organ. These observations suggest that the constitutive activation of ERK1/2 and AKT pathways in vitro does not influence proliferation and/or cell death of these cells in normal conditions or that these events occur in a narrow window before c-Kit\textsuperscript{+} cells undergo differentiation. On the other hand, in vitro experiments showed a better proliferation and growth potential of c-Kit\textsuperscript{TgD814Y} CSCs purified from adult c-Kit\textsuperscript{TgD814Y} mice indicating that the mutation of the receptor is by itself capable to fully activate the proliferation program of these cells.

To test the efficacy of the transgene in heart regeneration, we took advantage of the CI technique.\textsuperscript{44,45} CI was chosen because it is able to induce a focal, transmural and reproducing...
c-Kit activation for cardiac repair
S Di Siena et al

Cible heart damage. Transgenic mice were more resistant to the injury (Figure 4). All mice survived after the CI and showed cardiac tissue repair within 1 month after damage, suggesting a protective role by the c-Kit TgD814Y transgene. Moreover, a consistent reduction of fibrotic area was observed after CI in transgenic mice (Figure 4f). Nine days after the CI the number of c-Kit+ cells was increased in the damaged area of c-Kit TgD814Y mice compared with c-Kit+/+.
Figure 6  CSCs are activated by c-KitTgD814Y. (a) Flow cytometry of CSCs isolated from c-Kit+/+ and c-KitTgD814Y hearts. (d and e) Clone and sphere formation assay was performed on c-Kit+/+ and c-KitTgD814Y CSCs and the results are summarized in the histogram bar. Representative images of clones is shown. Data are reported ± S.D. *P<0.05. (f) WB and densitometric analysis on protein extracts from c-KitTgD814Y and c-Kit+/+ CSCs of three different experiments. (g and h) Clone and sphere formation assay was performed on c-KitTgD814Y CSCs after 14 days of treatment with AKT (MK2206, 1 μM), ERK inhibitor (PD98059, 100 μM) or the combination of them. Data are reported ± S.D. *P<0.05 versus untreated sample (NT)
mice (Figure 5b). Because it has been reported that ERK1/2 and AKT phosphorylation might induce migration and/or differentiation of stem cells,17,39,46 our findings indicate that these mechanisms might also occur following CI in c-KitTgD814Y mice. This hypothesis is in line with the observation of numerous elongated c-Kit+ cells in the damaged area which express the endothelial CD31 marker and with the higher capillary density found in peri-damaged area of transgenic hearts, allowing to speculate that c-Kit activation is required for novel vessel formation during the early stages of heart repair. These results are in line with the recent findings showing that c-Kit+ cells are committed to the endothelial differentiation42,47,48 and, for the first time demonstrate that activation of MAPK but not AKT signaling pathway is fundamental for c-Kit-mediated endothelial differentiation. Moreover, the results obtained with BrdU incorporation also suggest a role of c-KitTgD814Y receptor in myocytes regeneration, following heart injury favoring cardiomyocyte turnover for heart repair. The in vivo bi-potent fate of c-KitTgD814Y precursors to support both endothelial and cardiomyocyte differentiation was confirmed in vitro by purifying and selectively culturing c-KitTgD814Y CSCs and showing that both MAPK and AKT pathways are required for CSC growth and clonogenic properties as well as for their endothelial and myogenic commitment. Overall, these results highlight the crucial role of c-Kit receptor activation in heart repair with distinct involvement of AKT and/or ERK1/2 signaling pathways to mediate c-Kit functions in both healthy and injured hearts.

Materials and Methods

Mice generation. The generation of c-KitTgD814Y transgenic mice was obtained by substituting G to T 2468 in the c-Kit gene of the murine BAC RP23-309C11 through homologous recombination as previously described.49,50

The murine BAC RP23-309C11, containing 80 kb of c-Kit genome sequence and 68 kb of sequence upstream and 57 kb of sequence downstream the c-Kit initiation and stop codons, respectively, was engineered substituting the G to T 2468 to generate c-KitTgD814Y transgenic mice. Electrocompetent DH10B bacteria with the BAC RP23-309C11 were electroporated with 100 bp oligos containing complementary 20 bp mutated regions around the G to T 2468 nucleotide responsible for the switch of aspartic to tyrosine amino acid. Following the first homologous recombination driven by a temperature-inducible mini-λ phage, a second electroporation, was performed using a 100 bp oligos pairs with the G to T 2468 substitution surrounded with endogeneous c-Kit sequence to replace the first oligos pairs and leave the single point mutation. Following the second homologous recombination, the mutation was inserted in the BAC RP23-309C11. The G to T 2468 mutation was confirmed by sequencing analysis and the purified BAC was added to the 3′ ACT AG-3′ mutation was confirmed by sequencing analysis and the purified BAC was

The 16th c-Kit intron had been replaced by the 1.6 Kb PGK-Neo cassette. Heterozygote c-Kit+/− mice were generated by replacement of the 16th intron with a PGK-Neo cassette through homologous recombination, resulting in functional inactivation of the gene. A 7 kb BamHI fragment of the mouse c-Kit gene spanning 600 bp EcoRV-homologous recombinant ES colonies was performed by Southern blot using a diagnostic band. The identified recombinant ES colonies were injected in mouse blastocysts by substituting G to T 2468 in the c-Kit through homologous recombination as previously described.49,50

.Additionally, the left arm of homology was added to the Xhol site of the construct. A 11 kb Nol site targeting fragment (containing sequentially the left arm of homology, the PGK-Neo cassette, the right arm of homology and the PGK-TK cassette, see Supplementary Figure 1) was electroporated in ES cells, which were subsequently treated with neomycin and gancyclovir for positive and negative selection, respectively. Screening of recombinant ES colonies was performed by Southern blot using a diagnostic band. The identified recombinant ES colonies were injected in mouse blastocysts by substituting G to T 2468 in the c-Kit through homologous recombination as previously described.49,50

Bone marrow and blood cells isolation. Bone marrow cells were isolated from adult mice by flushing both femurs and tibias with 2 ml of PBS using a 25-gauge needle syringe. Cells were pelleted, washed and re-suspended for the analysis.

For white blood inflammatory and remodeling marker staining, 200 μl of blood samples were collected from mice eyes in heparin-treated vials then red blood cells were lysated using RBC Lysis Buffer (BioLegend, London, UK) as the protocol.

Flow cytometry analysis. Bone marrow cells were re-suspended in FACS buffer (PBS:2% PBS:2 mM EDTA) and stained for 1 h at 4 °C with rat anti-c-Kit CD117 Alexa Fluor 647 (Invitrogen: RM6221, Thermo Fisher Scientific-Life Technologies, Waltham, MA, USA) antibody. Dead cells were stained with 7 Amino-Actinomycin D dye (Sigma Aldrich).

White blood cells were stained in 100 μl of FACS buffer with rat anti-CD11b PE-Cy7 (Pharmingen: 25-0112, Gurgaon, Haryana, India) and rat anti-GR-1 APC antibodies (Pharmingen: 17-5931) at 4 °C for 1 h. Dead cells were stained with Sytox Blue dye. Analysis was performed with CyAn cytofluorimeter (Dako, Milano, Italy).

Isolated CSCs analysis was performed on FACS Canto II with FlowJo software to identify c-Kit expression by mouse monoclonal APC-conjugated anti-c-Kit antibody (Miltenyi). Appropriate labeled isotype controls were used to define the specific gates.

mRNA extraction and RT-PCR analyses. mRNA was extracted from CSCs with Trizol (Sigma Aldrich) using QIAamp RNAeasy miniKit (Milano, Italy) following the manufacturer’s instructions. Traces of genomic DNA were removed before reverse transcription using DNA Free Zymo Research kit. RNA was quantitated using a Nanodrop 2000 Spectrophotometer (Thermo Fisher Scientific, Waltham, MA, USA) and 0.5–1.0 μg of total RNA was reverse-transcribed using SuperScript II transcriptase (Life Technologies/Invitrogen/Thermo Fisher Scientific) according to the manufacturer’s instructions using the High Capacity cDNA Kit (Applied Biosystems).

Reverse transcription-qPCR was performed with the TaqMan Primer/Probe sets (specific primers were purchased from Invitrogen and the relative catalog numbers are available upon request using StepOne Plus Real Time PCR System (Applied Biosystems) following the manufacturer’s instructions.

Data were processed by the ΔCt method using StepOne Software v2.3. mRNA was normalized with GAPDH and all reactions were carried out in triplicate.

For semiquantitative RT-PCR, primers were as follows: CD31 forward 5′-TGG AGAGTTCTCCTCC-3′; GAPDH forward 5′-GTGTCTCTTTGCGCT AGGT A-3′; VEGFR1 forward, 5′-GTT AGAGTTCTCCTCC-3′; VEGFR2 forward, 5′-GTGTCTCTTTGCGCT AGGT A-3′; VEGFR1 reverse, 5′-CA CAARTGTGCIAACGCTGT-3′; VEGFR2 reverse, 5′-GTGTCTCTTTGCGCT AGGT A-3′; p-AKT forward, 5′-TGG AGAGTTCTCCTCC-3′; p-AKT reverse, 5′-TGG AGAGTTCTCCTCC-3′; p-AKT (Ser473) forward 5′-sc-154; rabbit anti-pAKT1/2/3-ser473 (1:100) sc-7985; mouse anti-AKT1/2/3 (1:100) sc-168; mouse anti-pERK1/2 (1:1000) sc-7383; rabbit anti-ERK 2 (1:1000) sc-244; p-ERK1/2 (1:100) sc-494; p-ERK1/2 (1:100) p-ERK1/2 (1:1000) (all from Cell Signaling) at dilutions suggested by the manufacturers. Proteins were detected by chemiluminescence using horseradish peroxidase-conjugated 2Abs and the Alliance UVITEC Cambridge system (Eppendorf, Milano, Italy).

Heart injury. The CI was performed by a technician blinded to the genotype of mice, essentially as previously reported. Briefly, under general anesthesia with Avertin (Sigma, 250 mg/kg), mice were subjected to surgery. The abdominal cavity was opened and CI was inflicted through the intact diaphragm on the heart pushed toward the probe. Heart damage was performed by applying for 5 s a 5 mm diameter metal probe cooled to −196 °C with liquid nitrogen. The abdominal cavity was closed with sutures. Mice received 500 μl of glucose solution (5% glucose in physiologic solution) and the analgesic Atroalg (3 mg/kg), soon after the surgery. Mice were killed and their hearts harvested 3 (c-Kit+/− n = 2; c-KitGrD814Y/c-Kit+/− n = 2), 9 (c-Kit+/− n = 10; c-KitGrD814Y/c-Kit−/− n = 8) and 30 (c-Kit+/− n = 12 and c-Kit-c-Kit−/− n = 13) days after the CI.

Tissue harvesting, immunofluorescence, immunohistochemistry and TUNEL assay. Hearts were collected at different ages, the atria were removed and the ventricles were placed in Hank’s balanced solution (Euroclone, Pero (MI), Italy) sowing gently to remove the remaining blood from the chambers. After washing in PBS, the ventricles were embedded in OCT (Bio-Optica, Milano, Italy), frozen in isopentane chilled with liquid nitrogen and stored at −80 °C before immunohistochemistry and immunofluorescence analyses as described in Supplementary Methods. In order to preserve GFP, ventricles taken from pKFGFP mice and c-KitGrD814YpKFGFP mice were pre-fixed in PBS/4% PFA pH 7.4 (Sigma) overnight at 4 °C and then included in OCT. Embryos were directly included in OCT, frozen in isopentane chilled with liquid nitrogen and stored at −80 °C. For EGFP+ cardiac cell count, at least 20 sections of 5 μm thickness were collected from each heart and analyzed for c-Kit and EGFP staining at different postpartum developmental time for pKFGFP mice and c-KitGrD814YpKFGFP mice: at 1 day n = 4 and n = 5 mice, respectively; at 10 days n = 4 and n = 6 mice, respectively; at 2 months old n = 5 and n = 6 mice, respectively. Images were acquired with Zeiss microscope (Axioskop 2 plus, Zeiss, Carl Zeiss Microscopy, Thornwood, NY, USA). EGFP-positive cardiac cells were counted throughout the left and right ventricle for each section. The EGFP-positive cell number was calculated as mean number per section.

Immunofluorescence was performed in 5 μm-thick sections fixed in PBS/4% PFA for 10 min at room temperature before staining. After permeabilization and blocking with PBS/1% BSA, slices were incubated with primary antibodies diluted in PBS/1% BSA overnight at 4 °C. Undamaged and damaged heart sections were stained with the following primary antibodies: goat anti-c-Kit (R&D) 1:100 and rat anti-Cd31 (eBioscience: 14-0311) 1:100; rabbit anti-v-sMA (Abcam: ab5664) 1:100. In order to reveal c-Kit receptor in embryos, sections were stained with goat anti-c-Kit (R&D) diluted 1:50. Secondary antibodies anti-rat Alexa Fluor 488, anti-rabbit FITC and anti-goat Cy5 all from Jackson were diluted 1:300. Nuclei were stained by Hoechst 33342 solution.

To quantify fibril thick, transversal serial sections of ventricles (5 μm of thickness) were collected, fixed in Bouin solution (Sigma) and stained with Masson’s Trichrome kit (Sigma). Collagen was detected in blue and myocardiad cells in red. Images were acquired with Axioskop 2 plus microscope. Images were used to quantify the fibril area. The fibril residual area of each collected section was measured in pixels and expressed as percentage respect to total area, without the lumen. The injured size was then calculated as the mean percentage of slices for all ventricles.

Aptosis was evaluated on three heart sections derived from three different c-Kit+/− and c-KitGrD814Y/c-Kit−/− mice 9 days after the CI by following TUNEL assay (Roche) manufacturer’s instructions.

Protein lysates obtained from CSCs (~50 μg) were separated on 10% SDS-polyacrylamide gels. After electrophoresis, proteins were transferred onto nitrocellulose filters, blocked with either 5% dry milk or 5% bovine serum albumin, and incubated with Abs against AKT (#9272), p-AKT (#4058 S), ERK1/2 (#9102) and pERK1/2 (#9101) (all from Cell Signaling) at dilutions suggested by the manufacturers. Proteins were detected by chemiluminescence using horseradish peroxidase-conjugated 2Abs and the Alliance UVITEC Cambridge system (Eppendorf, Milano, Italy).
BrdU, WGA and IB-4 stainings. Damaged hearts from BrdU-treated mice were perfused with buffered formalin and embedded in paraffin, and 5 μm-thick sections were cut. Antigen retrieval was achieved using Target Retrieval Solution, Citrate pH 6 (DAKO). Myocyte cytoplasm was detected using an antibody against α-actinin (1:50 dilution, Clone H-300, Santa Cruz Biotechnology) for 3 h at 37 °C and this was detected with anti-rabbit Alexa Fluor 647 (1:100 dilution; Jackson Immunoresearch Laboratories, Inc., West Grove, PA, USA). BrdU was detected using an antibody against BrdU (1:50 dilution, Roche) for 45 min at 37 °C. This antibody was detected with an anti-mouse Alexa Fluor 488 (1:100 dilution; Jackson Immunoresearch). Newly formed myocytes were detected through double staining for BrdU and α-actinin. Secondary antibody incubation was carried out at 37 °C for 1 h. Wheat germ agglutinin (Alexa Fluor 594 conjugated WGA; Life Technologies) staining was performed for cardiomyocyte dimension analysis. The nuclei were counterstained with the DNA-binding dye, 4, 6-diamidino-2-phenylindole (Sigma) at 1 μg/ml. Sections were mounted in Vectashield and analyzed and scanned using confocal microscopy (Leica Microsystems TCS SP5, Milan, Italy). ImageJ software was used to quantify the cardiomyocyte area.

For IB-4 staining, 5 μm heart sections were deparaffinized and treated with 1 mM sodium citrate solution (Santa Cruz Biotechnology), pH 6.0, in microwave for 10 min. After permeabilization with 0.1% PBS-Triton X-100 v/v at RT for 8 min, sections were blocked with PBS-1% BSA w/v for 30 min at RT and capillaries were stained with IB-4 - FITC conjugated (Sigma) overnight at 4 °C. Nuclei were stained with Hoechst 33342. Slides were mounted with glycerol in 50 mM Tris- HCl solution pH 8.7 (1:1). Images were acquired by Nikon Eclipse Ti - S microscope. The number of capillary was counted in 10 images/section and reported as fold change.

Statistical analyses. Statistical analysis was performed with GraphPad Prism version 6.00 for Macintosh (GraphPad Software, Inc., La Jolla, CA, USA). Quantitative data are reported as mean ± S.E. or mean ± S.D. and binary data by counts. Significance between two groups was determined by Student's t test or multiple groups ANOVA was used. A P value < 0.05 was considered significant. Bonferroni post hoc method was used to locate the differences. In these cases, the type 1 error (α = 0.05) was corrected by the number of statistical comparisons performed. If not specified, a n = 4 sample size was used for the in vitro cell and molecular biology experiments. The Kruskal–Wallis (for multiple-group comparison) and the Mann–Whitney U tests (for comparison between two groups) were performed.

Conflict of Interest
The authors declare no conflict of interest.
