ABSTRACT
Poor ovarian response represents an increasingly common problem. This systematic review was aimed to identify the most effective treatment protocol for poor response. We searched MEDLINE, EMBASE, and The Cochrane Library from 1980 to October 2015. Study quality assessment and meta-analyses were performed according to the Cochrane recommendations. We found 61 trials including 4997 cycles employing 10 management strategies. Most common strategy was the use of gonadotropin-releasing hormone antagonist (GnRHant), and was compared with GnRH agonist protocol (17 trials; n = 1696) for pituitary down-regulation which showed no significant difference in the outcome. Luteinizing hormone supplementation (eight trials, n = 847) showed no difference in the outcome. Growth hormone supplementation (seven trials; n = 251) showed significant improvement in clinical pregnancy rate (CPR) and live birth rate (LBR) with an odds ratio (OR) of 2.13 (95% CI 1.06–4.28) and 2.96 (95% CI 1.17–7.52). Testosterone supplementation (three trials; n = 225) significantly improved CPR (OR 2.4; 95% CI 1.16–5.04) and LBR (OR 2.18; 95% CI 1.01–4.68). Aromatase inhibitors (four trials; n = 223) and dehydroepiandrosterone supplementation (two trials; n = 57) had no effect on outcome.

KEY WORDS: Assisted conception, in vitro fertilization, ovarian stimulation, poor ovarian response

INTRODUCTION
Poor ovarian response (POR) is a challenging situation in assisted reproduction. There is a lack of consensus on the definition of POR and a huge variation in treating women with previous POR. However, the most common criterion to diagnose POR is retrieval of low number of oocytes despite adequate ovarian stimulation in an assisted conception cycle. The ESHRE working group on POR definition (the Bologna criteria) reached a consensus on the minimal criteria needed to define POR by the presence of two of the following three features: (i) Advanced maternal age (≥40 years) or any other risk factor for POR; (ii) a previous characterized POR cycle (≤3 oocytes with a conventional stimulation protocol); (iii) an abnormal ovarian reserve test (antral follicle count <5–7 follicles or anti-Mullerian hormone (AMH) <0.5–1.1 ng/ml). It was also proposed by the working group that two episodes of poor ovarian response after maximum stimulation deemed sufficient to define a patient as POR in the absence of other criteria. The suggested incidence of POR ranges from 9% to 25%. Various controlled ovarian hyperstimulation protocols and strategies have been used in this group of women to improve reproductive outcome, but the success rate still remains low.

To date, there are various observational studies, randomized controlled trials (RCTs), and systematic reviews reported on this subject. However, either the studies are too specific by trying to address only one treatment strategy, or they include observational studies and nonrandomized studies in their meta-analysis. The aim of
our systematic review is to appraise all the existing protocols applied to poor responders by including evidence generated from RCTs.

**METHODS**

The review was formulated using population, intervention, comparison, outcome, and design structure. Poor responders to ovarian stimulation formed the study population. All types of intervention subjected to RCTs were included in the review. The interventions were analyzed and compared with the control group used in the study. Two or more trials with identical design and interventions were analyzed by meta-analysis. Our outcome measures were number of oocytes retrieved per cycle, live birth rates (LBR), and clinical pregnancy rates (CPR).

We searched the literature on MEDLINE (1980-October 2015), EMBASE (1980-October 2015), and The Cochrane Library (2015) for relevant citations using the keywords, “poor responders, controlled ovarian hyperstimulation, reduced ovarian response, diminished ovarian response, low AMH, assisted conception, and in vitro fertilization (IVF).” The reference lists of all known primary and review articles were examined to identify cited articles not captured by the electronic searches. Language restrictions were not applied. A systematic search for all RCTs was carried out. Reference lists from retrieved articles and related articles were checked for relevant studies. All studies addressing the research question and satisfying our inclusion criteria were included in the review. The review protocol was registered with the PROSPERO Registry (CRD42013004190).

**Data collection and analysis**

The electronic searches were scrutinized, and full manuscripts of all citations that were likely to meet the predefined selection criteria were obtained. Two review authors (Yadava Bapurao Jeve and Harish Malappa Bhandari) independently assessed trial quality and extracted data. Studies which met the predefined and explicit criteria regarding population, interventions, comparison, outcomes, and study design were selected for inclusion in this review. When discrepancies occurred, they were resolved by consensus (Yadava Bapurao Jeve and Harish Malappa Bhandari). We performed meta-analysis when two or more trials were comparable in design and protocol. Data were analyzed using Review Manager (RevMan) [Computer program]. Version 5.1. Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2014. For each study, the treatment effect was measured with an odds ratio (OR) for dichotomous outcomes and mean differences for continuous outcomes and random effect models that were presented with their corresponding 95% confidence intervals (CI).

**Inclusion criteria**

Only RCTs that used suitable definition for POR and used different therapeutic approaches for ovarian stimulation of poor responders in assisted conception were included in the study. The trials reported after publication of the Bologna criteria for poor responders were analyzed as per this criteria.[2]

**Exclusion criteria**

All observational studies or quasi-randomized studies and studies in which poor responders were not defined were excluded from the study.

**Intervention groups**

The interventions were grouped as below:

1. Gonadotropin-releasing hormone antagonist (GnRHant) protocols
2. Protocols using luteinizing hormone (LH) as an adjuvant
3. Protocols using growth hormone (GH) as an adjuvant
4. Protocols using transdermal testosterone as an adjuvant
5. Protocols using aromatase inhibitors as an adjuvant
6. Protocols using dehydroepiandrosterone (DHEA) as an adjuvant
7. Protocols using recombinant human chorionic gonadotropin as an adjuvant
8. Natural cycle
9. Protocols using various other adjuvants
10. Various modifications to GnRH agonist (GnRHa) protocol.

**Types of outcome measures**

To bring uniformity in assessment, we analyzed the most relevant primary outcomes of LBR and CPR per cycle. The secondary outcome measure was the number of oocytes retrieved per cycle.

**Quality and risk of bias of included studies**

We included only RCTs in this systematic review – some were blinded and/or placebo-controlled, but others were not. Quality analysis was performed using internationally accepted Cochrane tools. GRADEpro. [Computer program on www.gradepro.org]. Version [2014]. McMaster University, 2014, was used to produce a summary of findings, tables for meta-analysis; this shows significant effects with interventions. A risk of bias table was produced using Review Manager (RevMan) [Computer program]. Version 5.1. Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2014, and is summarized in Figure 1. Using these tools, we have classified overall quality of evidence as moderate to high grade.

**RESULTS**

A total of 61 RCTs (4997 assisted conception cycles) were included in this study. The treatment approaches were
categorized into 10 groups (as mentioned above), the most common being the use of GnRHant versus GnRHa for pituitary downregulation in 17 RCTs. The characteristics of the included studies are described in Table 1.

1. GnRHa versus GnRHant for pituitary downregulation:
   Seventeen RCTs (n = 1696) that met the criteria were subjected to meta-analysis [Figure 2]. The results suggested no significant difference in the number of oocytes retrieved (mean difference 0.09; 95% CI 0.53–0.36) and no difference in CPR with an OR of 1.24 (95% CI 0.88–1.73)

2. LH supplementation: Eight RCTs (n = 847) assessed the role of supplementation to ovarian hyperstimulation but found no difference in CPR (OR 1.32; 95% CI 0.93–1.87)

3. GH supplementation: None of the seven RCTs (n = 251) individually had shown benefit of GH supplementation in improving CPR, but the pooled data from these studies showed a significant improvement in CPR (OR 2.13; 95% CI 1.06–4.28). Of these, only four studies (n = 27) reported LBR and the pooled data showed

| Ferraretti (2004)      | n=104 (54 and 50) | Recombinant LH in addition to the increased dose of FSH | An increased dosage of FSH                     | Number of oocytes 53 versus 68               | Number of oocytes 5.89 versus 5.62 CPR 5 versus 3 CPR 2 versus 3 |
| Demiri (2005)          | n=106 (53 and 53) | Recombinant LH in addition to the increased dose of FSH | Increased dosage of FSH                        | Number of oocytes CPR 22 versus 11           |                                               |
| Fernández Ramírez (2006) | n=34 (16 and 18) | rLH 75 IU b.i.d. (150 IU/day) starting on the day of GnRHant initiation until hCG trigger | GnRHant without rLH |                                               | Three-arm study with addition of r LH and hCG supplementation |
| Polidoropoulous (2007) | n=136 (68 and 68) | rLH 75-150 IU/day until hCG criteria were met     | GnRHant protocol                               | Number of oocytes 4.8 versus 5.6             | CPR 17 versus 15                             |
| Berkkanoglu (2007)     | n=97 (46 and 51)  | 600 IU of rFSH plus daily supplementation with 75 IU of rLH | 600 IU of rFSH as the control group            | Number of oocytes CPR 13 versus 14           |                                               |
| Ruvolo (2007)          | n=42 (24 and 18)  | rLH 75-150 IU/day from 8th day of ovarian stimulation until hCG criteria were met | GnRHant and rFSH without further LH addition  | Clinical pregnancy 10 versus 4               | Three-arm study with addition of r LH and hCG supplementation |
| Barrenetxea (2008)     | n=84 (42 each)    | GnRHant and rFSH and rLH                         | GnRHant and rFSH alone                        | Number of oocytes 5.43 versus 5.66 CPR 10 versus 9 CPR 16 versus 15 |
| Musters (2012)         | n=116 and 128    | rFSH and rLH (2:1 ratio)                          | rFSH alone                                     |                                               | Unblinded study                             |
| **Protocols using GH as an adjuvant** |                  |                                                  |                                               |                                               |                                             |
| Owen, (1991)           | n=25 (13 and 12)  | GH 24 IU i.m./day on alternate days, starting simultaneously with HMG until the day of hCG administration | Use of placebo                                | CPR 4 versus 1                                | LBR 4 versus 0                             |
| Zhuang (1994)          | n=27 (12 and 15)  | GH 12 IU i.m./day on alternate days              | No placebo                                     | CPR 5 versus 2                                | LBR 4 versus 2                             |
| Hughes (1994)          | n=33 (21 and 12)  | In addition to commencing HMG, a second daily injection of GH 12 IU i.m. daily for up to 12 days or until hCG criteria were met | Placebo                                        | Number of oocytes 5 versus 5 Placebo-controlled double-blind |
| Bergh (1994)           | n=40 (20 each)    | GH 0.1 IU/kg body weight per day was given s.c. as pretreatment and during stimulation with HMG | Placebo                                        | CPR 3 versus 2                                | Double-blind, placebo-controlled           |
| Dor (1995)             | n=14 (7 and 7)    | GnRHAs/HMG/GH (18 IU on alternate days, total dose 72 IU) | GnRHAs/HMG/placebo                            | CPR 0 both groups Placebo-controlled double-blind |
| Suikkari (1996)        | n=22 (16 and 6)   | GnRHs, gonadotropin in a "boost" flare-up protocol for 4, or 12 IU of human GH | Placebo                                        | CPR 2.4 versus 2                              | Double-blind placebo-controlled             |
| Howles (1999)          | n=196 (96 and 100) | Long luteal buserelin 0.5 mg, 1 mg/day GH releasing factor s.c. with HMG 300 IU/day i.m. from the day of down-regulation | No supplement                                  | CPR 8 versus 8                                | LBR 5 versus 4 Multicenter double-blind, placebo-controlled study |
| Study            | Population | Intervention                                                                 | Comparison            | Outcome                           | Remark                                    |
|-----------------|------------|-------------------------------------------------------------------------------|-----------------------|-----------------------------------|-------------------------------------------|
| Kucuk (2007)    | n=61       | GH co-treatment, daily s.c. injection of 4 mg from day 21 of preceding cycle along with GnRHa | No supplement         | Number of oocytes 6.5 versus 3.2  | GH co-stimulation to long luteal GnRHa regimen |
| Eftekar (2013)  | n=82       | GH and GnRHant protocol                                                      | GnRHant protocol (no placebo) | CPR 5 versus 5                   | Number of oocytes 6.1 versus 4.8          |
| Massin (2006)   | n=53       | Transdermal application of testosterone 15 days before FSH                    | Placebo               | CPR 4 versus 1, LBR 2 versus 1    | Number of oocytes 3.17 versus 3.56        |
| Fábregues (2009)| n=62       | Testosterone 20 µg/kg/day for 5 days transdermal application preceding ovarian stimulation | High-dose gonadotropin in association with a minidose GnRHa protocol | CPR 6 versus 4, LBR 6 versus 4 | Number of oocytes 4.1 versus 3.6          |
| Kim (2011)      | n=110      | 12.5 mg transdermal testosterone daily for 21 days in the cycle preceding ovarian stimulation | No placebo            | CPR 17 versus 8, LBR 15 versus 7  | Number of oocytes 4.6 versus 3.2          |
| Goswami (2004)  | n=38       | Let 2.5 mg daily from day 3 to 7, and rFSH 75 IU/day on days 3 and 8          | Long GnRH protocol and rFSH (300-450 IU/day) | CPR 3 versus 6                   | Number of oocytes 1.6 versus 2.1          |
| Kashyap (2005)  | n=55       | Let and GnRHant                                                             | No placebo, GnRHant protocol | CPR 3 versus 1                   |                                            |
| Ozmen (2009)    | n=70       | Let 5 mg/day for 5 days and GnRHant 0.25 µg/day                             | No placebo, GnRH      | CPR 8 versus 5                    |                                            |
| Mohsen (2013)   | n=60       | Let supplementation                                                        | GnRH protocol (micr   | CPR 4 versus 5                    |                                            |
| Artini (2012)   | n=48       | 25 mg three times a day of DHEA supplementation for 3 months previous to IVF cycle | No adjuvant           | CPR 6 versus 4                   | Number of oocytes 3.58 versus 2.67        |
| Wiser (2010)    | n=51       | 75 mg DHEA orally, once a day, at least 6 weeks before GnRHa long protocol  | No adjuvant           | CPR 7 versus 3                   | Number of oocytes 4.6 versus 3.2 and 3.5  |
| Berkkanoglu (2007)| n=99   | 600 IU of rFSH plus daily supplementation with 75 IU of rhCG               | 600 IU of rFSH        | CPR 10 versus 14                  | Three-arm study recombinant LH, hCG supple   |
| Morgia (2004)   | n=215 (114 and 101) | Natural cycle IVF                                                           | Microdose GnRHa flare from day 1 and 600 IU FSH | CPR 17 versus 10                  | Unblinded study                            |
| Jinno (1997)    | n=162 (82 and 80) | Oral 1.25 mg/day bromocriptine from day 4 to 6 in preceding cycle and then 4.5 mg/day, discontinued 7 days before the beginning of HMG administration | GnRHa long protocol   | CPR 25 versus 13                  | Unblinded, controlled trial: Bromocriptine rebound method |

|-----------------------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|----------------------------------|-------------------------------|
| Chung Hoon (1999)           n=70 (35 each) | Triptorelin 0.1 mg from day 21; HMG/FSH 300 IU/day i.m. from day of downregulation plus 120 mg/day pyridostigmine until hCG                                                                                     | No adjuvant          | CPR 9 versus 4                   | Number of oocytes 5.9 versus 3.7 | Double-blind, placebo-controlled study |
| Battaglia (1999)            n=34 (17 each)   | GNRHa + daily supplemented (16 g) with oral L-arginine                                                                                                                                                        | No adjuvant          | CPR 0 versus 2                   | Number of oocytes 1.6 versus 4.1 | Oral L-arginine + GNRHa        |
| Lok (2004)                  n=60 (30 in each) | Low-dose aspirin (80 mg daily) at the time of commencement of GNRHa in the preceding cycle and continuing until hCG                                                                                          | Placebo              | CPR 3 versus 2                   | Number of oocytes 4 versus 3     | Double-blind, placebo-controlled study |
| Dirnfeld (1991)             n=54 (28 and 26) | 600 µg/day of buserelin nasal spray on day 1 till hCG 1000 µg/day of buserelin nasal spray 15-30 days before ovulation induction, then 600 µg/day till hCG |                       | CPR 3 versus 2                   | Number of oocytes 7.0 versus 5.6 | Unblinded study                |
| Von Hoof (1993)             n=47 (25 and 22) | 225 IU/day i.m. HMG from day 3 for 5 days, increasing to 450 IU/day                                                                                                                                          | Unchanged dose       | Unblinded study                  |                               |                               |
| Rombauts (1998)             n=40 (18 and 20) | GNRHa from day 2. FSH (150 IU) from day 25 of previous cycle                                                                                                                                                  |                      | Number of oocytes 4.5 versus 6   | Controlled study                |                               |
| Dirnfeld (1999)             n=78 (40 and 38) | GNRHa - started in the midluteal phase and stopped before administration of gonadotropins                                                                                                                      |                      | CPR 5 versus 9                   | Number of oocytes 6.46 versus 7.73 | Unblinded study                |
| Raga (1999)                 n=30 (15 and 15) | 300 IU/day rFSH + 150 IU/day HMG                                                                                                              | Purified FSH         | CPR 4 versus 1                   | Number of oocytes 7.2 versus 5.6 | Prospective randomized study  |
| Garcia-Velasco (2000)       n=70 (34 and 36) | Leuprolide acetate 1 mg/d SC till menstruation and then stopped. 3 Amp HMG + 5 Amp FSH on days 1 and 2, 2 Amp HMG + 3 Amp FSH on days 3,4 and 5 from D6 |                      | CPR 5 versus 6                   | Number of oocytes 4.1 versus 6.9 | Unblinded study                |
| Akman (2000)                n=40 (20 each)  | Ovarian stimulation with no GnRH or GnRHa administration                                                                                                                                                | 0.25 mg of Cetrotide daily till hCG | CPR 1 versus 4                   | Number of oocytes 3.46 versus 3.25 | Unblinded study                |
| Akman (2001)                n=48 (24 in each) | Low-dose oral contraceptive on cycle day 1 for 21 days. On day 2 of menstruation leuprolide acetate (40 µg s.c./day) followed by gonadotropins                                                             | Gonadotropins from day 2 and later 0.25 mg of cetrotrel daily | CPR 6 versus 5                   | Number of oocytes 5.5 versus 4.5 | Unblinded study                |
| Marci (2003)                n=38 (19 each)  | Short flare up protocol using GnRH 0.1 mg/day triptorelin from day 2                                                                                                                                       | Daily dose of 0.25 mg Cetrotide and 375 IU/day rFSH | CPR 3 and 2                      |                               | Unblinded study                |
| Mohamed (2006)             n=30 (15 and 13)  | Buserelin 300 µg/day s.c. from day 1 of cycle and ovarian stimulation from day 3                                                                                                                          | Ovarian stimulation from day 3 and GnRHa 0.25 mg/day from day 8 | Number of oocytes 6 each         |                               | Unblinded study                |
| Kucuk (2007)                n=42 (21 each)   | Long protocol triptorelin 0.1 mg, 150 IU rFSH, triptorelin was halved to 0.05 mg and the rFSH was increased to 450 IU                                                                                       | Flare-up regimen of triptorelin. Along with triptorelin, 450 IU rFSH | Number of oocytes 6.8 versus 3.8 | Number of oocytes 6.8 versus 3.8 | Long protocol flare up regimen |

significantly improved LBR (OR 2.96; 95% CI 1.17–7.52) with GH supplementation [Figure 3 and Table 2]

4. Testosterone supplementation: A relatively smaller number of trials tested transdermal testosterone
supplementation in assisted conception cycles (three RCTs; n = 225). The meta-analysis showed significantly improved CPR (OR 2.41; 95% CI 1.16–5.04) and LBR (OR 2.18; 95% CI 1.01–4.68), but the number of oocytes retrieved was not statistically significant (mean difference 0.94; 95% CI 0.24–1.64), [Figure 4 and Table 3]

5. DHEA supplementation: Two RCTs (n = 99). DHEA supplementation was found to have no significant effect on the number of oocytes (mean difference 0; 95% CI –1.07–1.07) and CPR (OR 2.10; 95% CI 0.75–5.85)

6. Use of aromatase inhibitors: Letrozole supplementation was used in four trials (n = 223) and the pooled data failed to find any statistically significant CPR (OR 1.28; 95% CI 0.60–2.73)

7. Natural cycle: The natural cycle IVF was tested by only one trial (n = 215).[11] The CPR and number of oocytes retrieved were statistically similar in both groups

8. Other interventions: Various authors modified the GnRHa protocols or used various supplementations such as bromocriptine, pyridostigmine, L-arginine, and low-dose aspirin which are described in Table 1. None of these interventions showed any significant improvement in outcomes.

DISCUSSION

Our systematic review updates on the evidence on various strategies to improve reproductive outcome for POR. We analyzed 61 RCTs and 4997 assisted conception cycles which were divided into 10 categories based on the interventions used. The use of GnRHant protocol for pituitary downregulation is a commonly used approach for poor responders. GnRHant protocol offers several advantages. They cause immediate, rapid gonadotropin suppression by competitively blocking GnRH receptors in the anterior pituitary gland, thereby preventing endogenous premature release of LH and FSH. Our meta-analysis of 17 RCTs did not show any significant difference in CPR or number of oocytes retrieved with the use of GnRHant.[12-28]

LH aids maintain adequate concentrations of intraovarian androgens and promote steroidogenesis and follicular growth. It has been proposed that addition of LH to ovarian stimulation protocol may benefit poor responders. Meta-analysis of eight trials[13,29-33] did not show significant improvement in CPR with use of recombinant LH.

GH, insulin-like growth factor-1, and GH-releasing hormone increase the sensitivity of ovaries to gonadotropin stimulation and enhance follicular development. GH enhances oocyte quality by accelerating and coordinating cytoplasmic and nuclear maturation. There are some suggestions that GH-releasing factor supplementation may improve pregnancy rates in poor responders. The pooled data from eight RCTs in this review show significantly improved CPR and LBR with GH supplementation.[13,29-36] There was no significant heterogeneity in the included studies (τ^2 = 0.00, χ^2 = 0.98, df = 3 [P = 0.81]; τ^2 = 0%). However, none of the studies had independently found any significant benefit with GH supplementation. The

Figure 4: Use of testosterone supplement
total numbers in the meta-analysis are small to draw any definitive conclusions.

Androgen stimulates early stages of follicular growth and increases the number of preantral and antral follicles by the proliferation of granulosa and thecal cells and reduction in granulosa cell apoptosis. It is hypothesized that positive change in microenvironment in the ovaries may lead to an increase in the number and the maturity of oocytes in poor responder group.[37] Three randomized trials[38-40] have tested this approach and the meta-analysis shows significant improvement in LBR and CPR.

Aromatase inhibition was proposed to improve ovarian response to FSH in poor responders. Our meta-analysis included four RCTs and failed to show any improvement in outcome with the use of aromatase inhibitors.

It is proposed that DHEA changes the follicular microenvironment by reducing hypoxic inducible factor-1, thus improving the quality of oocytes. Pooled data from 2 RCTs showed no significant difference in CPR with DHEA supplementation.[41]

Natural cycle IVF offers several advantages such as low cost and low risk of multiple pregnancies and most importantly eliminates the risk of ovarian hyperstimulation syndrome. Morgia et al.[31] randomized natural cycle IVF and microdose GnRHa flare along with FSH. It was found that natural cycle IVF may be as effective as IVF using controlled ovarian hyperstimulation. No further trials with this approach were found for meta-analysis.

**Strengths and limitations**

Our study provides most comprehensive and up-to-date review on the topic of assessing most effective treatment for poor responders and included only RCTs. We divided different approaches into 10 categories and performed meta-analysis as appropriate. Previous reviews were very specific in addressing one treatment strategy, and they failed to provide any conclusive answer. Some reviews were methodologically limited as they included observational studies and nonrandomized studies in their meta-analysis.[47,49]

The major limitation of this review is related to its small population size. Although some adjuvant suppletions may appear to improve ovarian response and reproductive outcome, we recognize that the numbers are small to recommend their routine use in poor responders. There was significant heterogeneity in the definition of poor responders in these trials conducted before Bologna consensus criteria were recommended.

**Interpretation**

Our meta-analysis showed no difference in the number of oocytes retrieved or the CPRs with use of GnRHant. The pooled data from seven studies show significantly improved CPR and LBR with GH supplementation in the previous review.[44] Our meta-analysis adds a further RCT[50] (n = 82) which results in a 48% increase in sample size. GH supplementation showed some promising results; however, the numbers are small to draw any convincing conclusion. Our results for testosterone supplementation are consistent with the results of previous meta-analyses as there were no new RCTs.[51,52] Letrozole supplementation may result in improved FSH sensitivity and concentration, but this beneficial effect was not reflected in the results. A systematic review by Bosdou et al.[7] previously showed no difference in outcome with the use of letrozole. Two more RCTs have been undertaken[37,42] since the previous review, and we added a total of 68 cycles (43%) to the sample size in our review. However, the pooled data showed no significant difference in outcome with use of letrozole. The anti-aging effect of the adrenal androgen DHEA is thought to be the mechanism to improve ovarian response. Recent meta-analysis did not show significant improvement with the use of DHEA.[53] Only two RCTs were eligible for our meta-analysis, which failed to demonstrate any benefit.

**CONCLUSION**

Evidence from this review suggests that GH supplementation or transdermal testosterone supplementation to assisted conception treatment cycles is associated with an improved CPR and LBR in poor responders. However, it is essential to recognize that this evidence is derived from a small number of studies; hence, we feel that the current evidence is insufficient to recommend the routine use of either of these approaches. Other treatment strategies are not found to be useful in improving clinical outcome in poor responders. We recommend that the empirical use of adjuvants should be avoided pending good quality evidence from well-designed studies.
