ABSTRACT

**Aims.** We aim to study the composition and energetics of the circumstellar material of DK Cha, an intermediate-mass star in transition from an embedded configuration to a star plus disk stage, during this pivotal stage of its evolution.

**Methods.** Using the range scan mode of PACS on the Herschel Space Observatory, we obtained a spectrum of DK Cha from 55 to 210 μm as part of the DIGIT key program.

**Results.** Almost 50 molecular and atomic lines were detected, many more than the 7 lines detected in ISO-LWS. Nearly the entire ladder of CO from J = 14–13 to 38–37 (E_u/k = 4080 K), water from levels as excited as J_K=22, L. Cieza¹⁵, C. Dominik¹⁶,¹⁷, C. P. Dullemond⁸,¹⁸, M. M. Dunham², A. Glassgold¹⁰, M. van Kempen et al. (2010) for the similar source HH46, far-IR atomic, ionic, and molecular lines can constrain the properties of the disk, envelope, and outflow. The CO emission lines between $J = 14–13$ and $J = 19–18$, as well as [$O\text{I}$] and [$C\text{II}$], were observed from DK Cha with ISO-LWS, but other possible molecular species, such as OH and $H_2O$, were undetected (Lorenzetti et al. 1999; Giannini et al. 1999).

The large beam of ISO-LWS (90″) and its low spectral resolving power ($\Delta\lambda/\Delta \lambda = 200$) were insufficient to determine the origin (e.g., envelope versus outflow) of the CO emission. The preferred picture was of a small, quiescent hot core of ~300 AU around the protostar (Giannini et al. 1999), but observations of CO 4–3 and 7–6 indicate that this warm CO emission either originates outside the inner few thousand AU or cannot be heated simply by radiation from the central star (passive heating) (van Kempen et al. 2006); the far-IR and submm lines have different energies and critical densities, so they may originate in different regions.

The Herschel key programme Dust, Ice, and Gas In Time (DIGIT) aims to study the evolution of these three constituents through the star formation process by observing objects at different stages. This paper, along with a companion paper on HD100546, a stage II object (Sturm et al. 2010), presents the first results from the DIGIT science demonstration observations.

2. Observations
The launch of the Herschel Space Observatory (Pilbratt 2010) with the Photodetector Array Camera and Spectrometer (PACS) instrument (Poglitsch 2010) oboard, enables the acquisition of far-IR spectra with high spectral resolving power and good spatial (~9″) resolution. The range scan/SED mode provides a full spectrum (55–210 μm).

DK Cha was observed for a total of ~4 h on 10 December 2009 by the PACS spectrometer on the Herschel Space Observatory in pointed range-scan spectroscopy mode (obsid 1342188039 and 1342188040). An image slicer rearranges the light within a 5 × 5 array, with each spatial pixel (spaxel) covering 9′.4 × 9′.4. A grating disperses the light onto two 16 × 25 pixel Ge:Ga detectors. Observations were taken using nodding, in which two off-positions separated by ±6 arcmin in elevation were taken as “blank” sky, from which the signal is subtracted. Consequently, spatially diffuse lines (e.g., [$C\text{II}$]) are subtracted out.

The effective spectral resolving power was about 1000+500, lower than expected, because of the pointing error, which is perpendicular to the slit, and the effects of fringing on the continuum. The point-spread function of PACS increases towards longer wavelengths and is larger than a single spaxel, but is corrected in post-processing using the PACS instrument (Poglitsch 2010) onboard, enables the acquisition of far-IR spectra with high spectral resolving power and good spatial (~9″) resolution. The range scan/SED mode provides a full spectrum (55–210 μm).

Table 1. Detected gas lines within the PACS spectrum of DK Cha.

| Species         | Transition                  | $\lambda$ $\mu$m | $E_{\text{b}}$ $K$ | FHWM $K$ | Flux $b$ W m$^{-2}$ |

Notes. (a) Laboratory wavelength; (b) flux summed over all pixels in 10$^{-18}$ W m$^{-2}$. Typical line flux uncertainties are dominated by calibration uncertainties (~30–50%) and fringing (0.1 Jy at the longest wavelengths to 0.6 Jy at the shortest); (c) lines blended with above line; (d) Long line detected only in central spaxel and should not be compared to the fluxes of the summed spaxels; (e) detection resolved.

3. Results
3.1. Continuum
The total SED in Fig. 1 includes photometry from the literature (Alcalá et al. 2008; Spezzi et al. 2008; Evans et al. 2009, Nefs et al., in prep), combined with Spitzer-IRS spectroscopy and the PACS results. The photometric points were fitted by the SED fitter routine from Robitaille et al. (2007), the result parameters being shown in Table 2. Because of the the extinction and variability at short wavelengths, only points longwards of 3 μm were considered as input to the fit. The best-fit model is overplotted and divided into the contributions from the star, disk, and envelope. The short-wavelength IRS continuum is dominated by the flux from the disk, the longer wavelength IRS continuum covers...
the transition from disk to envelope, and the PACS continuum arises in the envelope. The model underestimates the observations in the near-IR and mid-IR, indicating that the disk emission is underestimated in the model.

The best-fit models of the SED grid indeed confirm the assumption of a nearly face-on configuration $<18^\circ$ with relatively low and equal envelope and disk masses of 0.03 $M_\odot$, indicative of a source in transition from stage I to stage II (Robitaille et al. 2007). The PACS continuum was not used to constrain the fit, the consistency with the predicted model (differences of $<10\%$) thus being encouraging, especially considering the calibration uncertainty of 30–50%.

### 3.2. Line inventory

Table 1 lists all gas lines that have been identified. Figure 2 shows the spectrum after subtraction of a polynomial fit to the continuum. We used a combination of the ISO line list$^2$ and the list published in Lerate et al. (2006) for the Orion bar. More lines may be detectable in this spectrum after PSF deconvolution. Some lines in Table 1 are only detected in the central spaxel. Owing to the fringing in other spaxels at short wavelengths and the PSF problems discussed above, these lines cannot be seen in the summed result of Fig. 2. Using spectra from both the summation of all 25 spaxels and from only the central spaxel, a large range of CO, H$_2$O, and OH lines were detected, ranging in excitation energies from a few hundred kelvin to over 3000 K. In addition, [O I] and [N II] were identified. Emission from [C II] at 157.7 $\mu$m is not seen. That line was detected by Lorenzetti et al. (1999), but was interpreted to be extended emission, associated with the galactic ISM. This component is subtracted out in our observations due to the nodding, which was not used in ISO-LWS.

### 3.3. Gas analysis

Infrared CO lines were previously detected by Giannini et al. (1999), but only up to CO $J = 19$–18. Assuming the lines to be optically thin, those could be fitted with temperatures ranging from $T = 200$ K to $T = 750$ K and densities from $n = 4 \times 10^6$ cm$^{-3}$ to $n = 5 \times 10^5$ cm$^{-3}$. The high $T$, low $n$ model, which produces the most emission in the high-$J$ lines, is overplotted in Fig. 3. As can be seen, this model severely underpredicts the intensity of the CO lines from higher transitions seen by Herschel. The other proposed models predict even less high-$J$ emission.

The CO level populations up to $J = 31$ (Fig. 3), can be fitted with two distinct rotational temperatures ($T_{\text{Rot}}$, a break occurring at about $E_{\text{up}} = 1500$ K. Most of the mid-J CO lines can be fitted by $T_{\text{Rot}} \sim 380$ K, while higher excitation lines are best fitted with $T_{\text{Rot}} \sim 1365$ K. In HH46 (van Kempen et al. 2010), UV photon heating (Spaans et al. 1995) predominates for lines with energies below 1700 K, while a non-dissociative C-shock has a more important effect than the emission from higher excitation lines. A similar model is plausible for DK Cha, but this issue will be explored in a forthcoming paper (Green et al. in prep).

Water was detected in a wide variety of transitions, up to $J_{\text{max}}$–$6_{10}$ at 71.93 $\mu$m with ($E/k = 843$ K). Water was not detected in ISO-LWS (Giannini et al. 1999) because the lines are 5 times weaker than the CO lines. The discovery of the $7_{07}$–$6_{10}$ line is indicative of high temperature, as confirmed by the high-$J$ CO lines. Given the possible identification of shocked CO and the geometry of DK Cha, it is likely that the water emission arises at least in part from either a non-dissociative C-shock or UV-heating of the quiescent material along the outflow cavity walls.

In addition, at least 9 lines of OH are detected. Since oxygen is rapidly transformed into H$_2$O at temperatures higher than 100 K and frozen out below that, either a very strong UV field or a dissociative shock is needed. OH is a major coolant for dissociative shocks (Neufeld & Dalgarno 1989). This dissociative shock is accompanied by a C-shock, which may explain the CO and H$_2$O analysis. Models from Wampfler et al. (in prep) also suggest that C-shock densities are often too low to account for both high excitation lines and at the same time not overproduce the 119 and 163 $\mu$m OH lines.

HD 100546 (Sturm et al. 2010), a Herbig Be star without an envelope, was chosen for early observations to be a source analogous to DK Cha, but more evolved. A comparison is useful because similar species are seen in its spectrum. Emission of H$_2$O and OH from the upper layers of a flared, but quiescent disk, similar to that around HD 100546 (Sturm et al. 2010), may account for some of the lines from DK Cha. However, accounting for the difference in distance, the CO lines from DK Cha are more than 10 times stronger, and higher excitation lines from H$_2$O are seen toward DK Cha.

A possible explanation of the stronger emission of DK Cha is an accretion shock onto the disk, where high densities and temperatures are present. Another possibility is a shock in the walls of the outflow, which will also be examined further in Green et al. (in prep.).

---

Fig. 1. SED of DK Cha using WFI $I$-band data, 2MASS ($J, H, K$) and Spitzer-IRAC (3.6 and 4.5 $\mu$m). The other bands, 5.8 and 8.0 $\mu$m not being shown due to saturation), Spitzer-MIPS (24, 70 and 160 $\mu$m), APEX-Laboca (870 $\mu$m) and SEST (1.2 and 1.3 mm). Overplotted are the best-fit model from the Robitaille et al. (2007) grid and the PACS and Spitzer-IRAS spectra. The MIPS 70 $\mu$m is corrected for saturation; the 160 $\mu$m for large-scale emission. The solid line is the full model, while the dashed line shows the envelope contribution, the dot-dashed the disk contribution, and the dotted that of the star. Photometric points are shown as diamonds. The short-wavelength points are not well matched. Fluxes at short wavelength ($<3\mu$m) are variable.

Table 2. Best-fit from Robitaille models.

| DK Cha characteristics          |                  |
|--------------------------------|------------------|
| Envelope mass                  | $0.03 M_\odot$   |
| Disk mass                      | $0.03 M_\odot$   |
| Luminosity                     | $29.4 L_\odot$   |
|                                 | Disk Inner Radius| $0.3$ AU        |

Notes. $^1$ Total $A_v$ of which $A_v = 5.2$ mag. is attributed to the envelope at an inclination of 18$^\circ$ and 2.7 mag. to more extended cloud.

---

$^2$ http://www.mpe-garching.mpg.de/iso/linelists/Molecular.html
Fig. 2. The spectrum from 55–190 \( \mu \text{m} \) of all spaxels added together, after removal of the continuum and rebinning to 0.5 \( \mu \text{m} \) resolution. Several dips or bumps (e.g., around 75 \( \mu \text{m} \)) are instrument artifacts. Inserts show expanded views of parts of the spectrum, with line identifications.

Fig. 3. Upper: CO line fluxes plotted versus \( J_{\text{up}} \). The ISO line fluxes are shown with triangles. A clear excess can be seen in the CO line fluxes from \( J_{\text{up}} = 20 \) onwards compared to the warmest model of 750 K proposed by Giannini et al. (1999) (dashed line). Lower: CO Rotational diagram, showing two distinct populations with a break around 1500 K in energy. The blended lines are excluded from the fit and the plot. CO lines with \( J_{\text{up}} \) larger than 31 are excluded from both plots, as these lines are detected only in the central spaxel.

4. Conclusions

We have found that the continuum models that fit the data of DK Cha are consistent with the interpretation that it is a transitional object between a stage I and stage II, with nearly equal masses in the envelope and disk and a nearly face-on geometry. The full PACS SED mode observations reveal an extremely rich spectrum of over 50 ionic, atomic, and molecular lines. With additional improvements to the spectral response function, we will be able to identify additional gas, ice, and dust features in the spectrum. The full range scan/SED mode will be able to probe many aspects of a protostellar object, from the ambient envelope to gas excited by ultraviolet radiation and by shocks.
