\textit{Received August 24, 2022}

Based on a recently developed relativistic density functional approach to color-superconducting quark matter and a novel quark-hadron transition construction which phenomenologically accounts for the effects of inhomogeneous pasta phases and quark-hadron continuity, we construct a class of hybrid equations of state applicable at the regimes typical for compact star astrophysics and heavy ion collisions. We outline that early quark deconfinement is a notable consequence of strong diquark pairing providing a good agreement with the observational data and driving the trajectories of the matter evolution during the supernovae explosions toward the regimes typical for the compact star mergers and heavy-ion collisions.

1. Introduction

The puzzling question for the origin of compact stars (CS) with masses exceeding 2 M\textsubscript{\odot} can be successfully addressed at present only within the supernovae (SN) explosion mechanism based on quark deconfinement in the stellar matter [1]. This serves as an indirect argument in favor of the existence of quark matter in cores of heavy CS. Binary CS mergers could produce a distinct postmerger gravitational wave signal [2]. These interesting applications are summarised in [3]. They are based on a hybrid equation of state (EoS) that has been constructed from hadronic and quark matter EoS developed within relativistic density functional (RDF) approaches [4, 5]. In this contribution, we summarize recent developments of the RDF approach to quark matter which address beyond confinement also the aspects of chiral symmetry breaking and color superconductivity. In particular the occurrence of a large diquark pairing gap modifies the phase structure and EoS of QCD at low temperatures and is thus of central interest for the discussion.

* Presented at the 29\textsuperscript{th} Conference “Quark Matter 2022” on ultrarelativistic nucleus-nucleus collisions, April 4-10, 2022, Kraków, Poland
of the existence and location of one or more critical endpoints (CEPs). A
developed constructive scheme generates thermodynamically consistent EoS
with multiple or absent CEP and provides a solid basis for discussing their
effects in simulations of astrophysical phenomena and heavy-ion collisions
(HIC).

2. Relativistic density functional for quark matter

The RDF approach from Ref. [5] is represented by the Lagrangian

$$L = \bar{q}(i\partial - m)q - G_V(\bar{q}\gamma_\mu q)^2 + G_D(\bar{q}\gamma_5\tau_2\lambda_A q)^2(\bar{q}\gamma_5\tau_2\lambda_A q) - U$$  \hspace{1cm} (1)

with two-flavor quark field $q_T = (u \ d)$, current quark mass $m$ and $G_V$, $G_S$
being coupling constants in vector repulsion and diquark pairing channels,
respectively. A chirally symmetric generalization of the potential energy
density functional inspired by the string-flip model (SFM) [4] reads

$$U = D_0 \left[ (1 + \alpha)\langle \bar{q}q \rangle_0^2 - \langle \bar{q}q \rangle_0^2 - (\bar{q}i\gamma_5\tau_2 q)^2 \right]^{1/3}$$

$$\simeq U_{MF} + \langle \bar{q}q - \langle \bar{q}q \rangle \rangle_0 \Sigma_{MF} - G_S(\bar{q}q - \langle \bar{q}q \rangle)_0^2 - G_{PS}(\bar{q}i\gamma_5\tau_2 q)^2.$$  \hspace{1cm} (2)

Here $\alpha$ and $D_0$ are constants and $\langle \bar{q}q \rangle_0$ is the chiral condensate in the vacuum.

The last line in Eq. (2) corresponds to the second order expansion of $U$
around the mean-filed solutions $\langle \bar{q}q \rangle$ and $\langle \bar{q}i\gamma_5\tau_2 q \rangle = 0$ labeled with the
subscript index “MF”. This expansion brings the present model to the form
of the NJL model with the mean-field scalar self-energy of quarks $\Sigma_{MF} = \partial U_{MF}/\partial \langle \bar{q}q \rangle$ and effective couplings in scalar $G_S = -\partial U_{MF}/\partial \langle \bar{q}q \rangle_0^2/2$ and
pseudoscalar $G_{PS} = -\partial U_{MF}/\partial \langle \bar{q}i\gamma_5\tau_2 q \rangle_0^2/6$ channels. In Ref. [5] model parameters $m = 4.2$ MeV, $\Lambda = 573$ MeV, $\alpha = 1.43$ and $D_0\Lambda^{-2} = 1.39$ were
fixed in order to reproduce the pion mass $m_\pi = 140$ MeV and decay constant
$F_\pi = 92$ MeV, with the scalar meson mass $M_\pi = 980$ MeV and the vacuum value of the chiral condensate per flavor $\langle \bar{u}u \rangle_0 = -(267 \text{ MeV})^3$. We
note that $\Lambda$ is a three-momentum scale which occurs in the smooth momentum cut-off by a Gaussian formfactor which regularizes divergent zero-point
terms. The behavior of $G_S$ and $G_{PS}$ as well as the effective quark mass
$m^* = m + \Sigma_{MF}$ is shown in Fig. [1] The dynamical breaking of chiral symmetry leads to $G_S \neq G_{PS}$ in the vacuum, while its dynamical restoration at high temperatures and/or densities is manifested by the asymptotic coincidence of the scalar and pseudoscalar couplings. This is reflected in the melt-down of $m^*$. Its vacuum value $m_0^*$ is controlled by the parameter $\alpha$ so,
that $m_0^* \to \infty$ at $\alpha \to 0$. For the mentioned set of parameters $m_0^* = 718$
MeV and the pseudocritical temperature at $\mu_B = 0$ defined by the peak of
the chiral susceptibility is 163 MeV. The quark matter EoS is obtained
3. Phase diagram of strongly interacting matter

High values of the effective quark mass at low $T$ and $\mu_B$ represent phenomenological confinement in the RDF approach. This makes description of strongly interacting matter in terms of quark degrees of freedom inadequate in the confinement region and requires matching the quark matter EoS to the hadron one yielding a hybrid quark-hadron EoS. Within the Maxwell construction of quark-hadron transition the matching point is defined by the baryon chemical potential $\mu_B^{\text{Max}}$ at which the pressures of two phases coincide, while the baryon density discontinuously jumps from $n_B^h|\text{Max}$ on the hadron side to $n_B^q|\text{Max}$ on the quark one. This picture ignores inhomogeneous structures in the quark-hadron interface known as pasta phases \[7\] and corresponds to a sharp interface between two phases. Accounting for those pasta phases would wash out the sharp quark hadron interface allowing for the existence of a mixed phase, which is restricted by the baryon chemical potentials $\mu_B^h$ and $\mu_B^q$ (corresponding to $n_B^h$ and $n_B^q$) from the hadron and quark sides, respectively. In Ref. \[8\], the EoS of the mixed phase
was parameterized by two pieces of parabolic functions. In Ref. \cite{9} such a two-zone interpolation scheme (TZIS) was further developed to the case of arbitrary fractions of electric charge and applied at finite temperatures. The parameters of these two parabolic functions were defined so that both the pressure $p$ and the baryon density $n_B$ remain continuous at the mixed phase boundaries. Continuity of $p$ is also required at the matching point of two parabolas $\mu_B^h = (\mu_B^q + \mu_B^h)/2$, while $n_B$ experiences a discontinuous jump of $\Delta n_B$. The TZIS is given a closed form with the parameterization

$$\mu_B^h = \mu_B^{Max}|_{T=0}(1-x)\sqrt{1-T^2/T_0^2},$$

$$\mu_B^q = \mu_B^{Max}(1+x),$$

$$\Delta n_B = n^*(T_{cep1} - T)^\beta(T - T_{cep2})^\beta \theta(T_{cep1} - T)\theta(T - T_{cep2}),$$

where $x = 0.01$, $n^* = 0$ or $0.15$ fm$^{-3}$, $T_{cep1} = 90$ MeV and $T_{cep2} = 15$ MeV correspond to high and low temperature CEPs and $\beta = 0.3265$ is the critical exponent of the 3D Universality class \cite{10}. The TZIS allows us to construct a hybrid quark-hadron EoS at arbitrary entropy per baryon $s/n_B$. Fig. 2 compares such an EoS to the one obtained within the Maxwell construction. Furthermore, having the edges of the mixed quark-hadron phase defined we can construct the phase diagram of strongly interacting matter that is shown in Fig. 3. It is remarkable that the transition from quark to hadron matter leads to a growth of $T$ along adiabates $s/n_B = const$ being a direct consequence of the reduction of the number of accessible microstates due to the transition to the color superconducting phase of quark matter \cite{5}.

4. Compact stars at vanishing and finite entropy

Entropy of the quark-hadron matter in the interiors of the proto NS remains approximately constant during SN explosions \cite{1}. Therefore, isen-
Fig. 3. Phase diagram of $\beta$-equilibrated electrically neutral quark-hadron matter in the $\mu_B - T$ (left panel) and $n_B - T$ (central and right panels) planes. The black dotted, dashed and solid curves correspond to the phase boundaries and the matching chemical potential discussed in the text. The color mapping of phases corresponds to the TZIS. The filled black circles show the CEPs, which on the right panel are to guide the eye. The colored solid, dashed and dotted curves show adiabates $s/n_B$ = const calculated within the Maxwell construction, the TZIS with $n^* = 0.15$ fm$^{-3}$ and $n^* = 0$, respectively. The green shaded area shows the region where $n_B$ discontinuously jumps within the TZIS with $n^* = 0.15$ fm$^{-3}$.

The tropic EoS of quark-hadron matter is phenomenologically interesting. We applied such EoSs shown in Fig. 2 to solving a problem of relativistic hydrostatic equilibrium [9]. The corresponding mass radius relations of cold NS ($s/n_B = 0$) and warm proto-NS ($s/n_B \neq 0$) are shown in Fig. 4. In the case of cold NS our approach provides agreement with the constraints from Refs. [11, 12, 13, 14, 15, 16] and gives the tidal polarizability of 1.4 M$_\odot$ mass stars $\Lambda_{1.4} = 540 - 550$ agreeing with Ref. [14]. Finite $s/n_B$ increases the radius of NS but leaves their maximal mass almost unchanged.

5. Conclusions

We developed a confining RDF for color-superconducting quark matter and produced a family of hybrid quark-hadron EoS with or without (multiple) CEP(s). Due to large values of the diquark pairing gap our approach favors early quark deconfinement, provides good agreement with the present astrophysical constraints and drives trajectories of the evolution of stellar matter during the SN explosions toward the temperatures range of HIC.
