Abstract

The construction of link polynomials associated with finite dimensional representations of ribbon quasi-Hopf algebra is discussed in terms of the formulation of an appropriate Markov trace. We then show that this Markov trace is invariant under twisting of the quasi-Hopf structure, which in turn implies twisting invariance of the associated link polynomials.
1 Introduction

The introduction of quantum algebras by Jimbo [15] and Drinfeld [5] lead to many remarkable developments in diverse areas of mathematical physics. One such was in the field of knot theory whereby a connection between the Yang-Baxter equation and the braid group was quickly established. The quantum algebras, being examples of quasi-triangular Hopf algebras, provide very systematic means to find solutions of the Yang-Baxter equation which in turn gives rise to representations of the braid group. Through a Markov trace formulation defined on each braid group representation, an invariant polynomial can then be computed for the knot or link associated with the closure of the braid [21, 24, 25, 27]. Extensions to accommodate the case of quantum superalgebras can be found in [20, 26].

Around the same time as the appearance of quantum algebras was Jones’s discovery of a new polynomial invariant [17], an evaluation of which may be undertaken through the simplest quantum algebra $U_q(sl(2))$ in its minimal (two-dimensional) representation. After this breakthrough researchers proceeded to obtain generalizations with the notable examples being the HOMFLY [11] and Kauffman [18] invariant polynomials. What soon became apparent was that the series of link polynomials associated with the fundamental representations of the (non-exceptional) quantum algebras and superalgebras coincided with the two-variable invariants developed in the wake of the discovery of Jones. More precisely, the invariants associated with the fundamental representations of the $U_q(gl(m|n))$ (which includes $U_q(gl(n))$) series belong to the class of HOMFLY invariants while those of the $U_q(osp(m|2n))$ (including both $U_q(o(m))$ and $U_q(sl(2n))$) series are of the Kauffman invariant type [24, 26]. It is important to emphasize, however, that by going to higher representations new results are obtainable. In particular, the type I quantum superalgebras consisting of $U_q(gl(m|n))$ and $U_q(osp(2|2n))$ admit one-parameter families of typical representations which give rise to two-variable link invariants in a natural way [4, 13, 19]. The work of Reshetikhin and Turaev [23] introduced further the notion of a ribbon Hopf algebra as a particular type of quasi-triangular Hopf algebra. All the quantum algebras fall into the class of ribbon Hopf algebras. The algebraic properties of ribbon Hopf algebras is such that an extension to produce invariants of oriented tangles is permissible. A tangle diagram is analogous to a link diagram with the possibility of having free ends. An associated invariant takes the form of a tensor operator acting on a product of vector spaces.

As a generalization of Hopf algebras Drinfeld proposed the concept of quasi-Hopf
algebras \[3\] whereby co-associativity of the co-algebra structure is not assumed. Any
quasi-Hopf algebra generally belongs to an equivalence class where each member is
related to the others by twisting \[3\]. The potential for applications of these structures
in the study of integrable systems is vast. They underly elliptic quantum algebras
\[7, 8, 9, 12, 16, 28\] which play an important role in obtaining solutions to the dynamical
Yang-Baxter equations \[2, 3\] and also twisting lies at the core of the construction of
multiparametric quantum spin chains \[10\].

In the context of knot theory, Altschuler and Coste \[1\] have identified the corre-
sponding ribbon quasi-Hopf algebras as the necessary underlying algebraic structure
to study tangle invariants (including closed link invariants). Here we wish to make
two important observations to this field of study. First, we will show that the class of
ribbon quasi-Hopf algebras is closed under twisting; i.e a twisted ribbon quasi-Hopf
algebra is again a ribbon quasi-Hopf algebra. Secondly, we assert that the link poly-
nomials computed from any finite dimensional representation of a quasi-Hopf algebra
are invariant with respect to twisting. Importantly, this implies that link polynomials
obtained from twisting the usual quantum algebras give us nothing new. In this re-
spect, one cannot find twist generalizations of the HOMFLY and Kauffman invariants.
For a very special class of twists this result has already been noted by Reshetikhin \[22\],
in which case the twisted quantum algebra is again a ribbon Hopf algebra. Here we
will prove the twisting invariance in full generality.

The paper is structured as follows. We begin by presenting the definition of a quasi-
Hopf algebra. Next we show how representations of the braid group are obtained from
a representation of any quasi-Hopf algebra. The third section deals with defining an
appropriate Markov trace on each braid group element which then affords a means
to obtain a link invariant. Finally, we demonstrate that the Markov trace is invariant
under any twisting.

## 2 Quasi-Hopf Algebras

Let us briefly recall the defining relations for quasi-Hopf algebras \[3\].

**Definition 1** : A quasi-Hopf algebra is a unital associative algebra \( A \) over a field \( K \) which is
equipped with algebra homomorphisms \( \epsilon : A \to K \) (co-unit), \( \Delta : A \to A \otimes A \) (co-product), an
invertible element \( \Phi \in A \otimes A \otimes A \) (co-associator), an algebra anti-homomorphism \( S : A \to A \)
(anti-pode) and canonical elements $\alpha, \beta \in A$, satisfying

\begin{align}
(1 \otimes \Delta)\Delta(a) &= \Phi^{-1}(\Delta \otimes 1)\Delta(a)\Phi, \quad \forall a \in A, \\
(\Delta \otimes 1 \otimes 1)\Phi \cdot (1 \otimes 1 \otimes \Delta)\Phi &= (\Phi \otimes 1) \cdot (1 \otimes \Delta \otimes 1)\Phi \cdot (1 \otimes \Phi), \\
(\epsilon \otimes 1)\Delta &= 1 = (1 \otimes \epsilon)\Delta, \\
(1 \otimes \epsilon \otimes 1)\Phi &= 1, \\
m \cdot (1 \otimes \alpha)(S \otimes 1)\Delta(a) &= \epsilon(a)\alpha, \quad \forall a \in A, \\
m \cdot (1 \otimes \beta)(1 \otimes S)\Delta(a) &= \epsilon(a)\beta, \quad \forall a \in A, \\
m \cdot (m \otimes 1) \cdot (1 \otimes \beta \otimes \alpha)(1 \otimes S \otimes 1)\Phi^{-1} &= 1, \\
m \cdot (m \otimes 1) \cdot (S \otimes 1 \otimes 1)(1 \otimes \alpha \otimes \beta)(1 \otimes 1 \otimes S)\Phi &= 1.
\end{align}

Here $m$ denotes the usual product map on $A$: $m \cdot (a \otimes b) = ab, \forall a, b \in A$. Note that since $A$ is associative we have $m \cdot (m \otimes 1) = m \cdot (1 \otimes m)$. For all elements $a, b \in A$, the antipode satisfies

$$S(ab) = S(b)S(a).$$

The equations (2.2), (2.3) and (2.4) imply that $\Phi$ also obeys

$$(\epsilon \otimes 1 \otimes 1)\Phi = 1 = (1 \otimes 1 \otimes \epsilon)\Phi.$$  

Applying $\epsilon$ to definition (2.7, 2.8) we obtain, in view of (2.4), $\epsilon(\alpha)\epsilon(\beta) = 1$. By applying $\epsilon$ to (2.5), we have $\epsilon(S(a)) = \epsilon(a), \forall a \in A$.

A distinguishing feature of quasi-Hopf algebras is that they are in general not co-associative; i.e

$$(1 \otimes \Delta) \cdot \Delta \neq (\Delta \otimes 1) \cdot \Delta.$$  

Thus for a given co-product the action extended to the $n$-fold tensor product space is not uniquely determined. Throughout we will adopt the convention to define a left co-product $\Delta_L$ which acts on the tensor algebra $A^\otimes n$ according to

$$\Delta_L(a \otimes b \otimes \ldots \otimes c) = \Delta(a) \otimes b \otimes \ldots \otimes c.$$  

We then recursively define the action

$$\Delta^{(n)} = \Delta_L \Delta^{(n-1)}$$

with $\Delta^{(1)} = \Delta, \Delta^{(0)} = I$.

The category of quasi-Hopf algebras is invariant under a kind of gauge transformation known as twisting. Let $(A, \Delta, \epsilon, \Phi)$ be a quasi-Hopf algebra, with $\alpha, \beta, S$ satisfying (2.5)-(2.8), and let $F \in A \otimes A$ be an invertible element satisfying the co-unit properties

$$(\epsilon \otimes 1)F = 1 = (1 \otimes \epsilon)F.$$
Throughout we set
\[
\Delta_F(a) = F \Delta(a) F^{-1}, \quad \forall a \in A,
\]
\[
\Phi_F = F_{12} (\Delta \otimes 1) F \cdot \Phi \cdot (1 \otimes \Delta) F^{-1} F_{23}^{-1}
\]
where the subscripts above refer to the embedding of the elements in the triple tensor product space. Then

**Theorem 1**: \((A, \Delta_F, \epsilon, \Phi_F)\) defined by (2.13, 2.14) together with \(\alpha_F, \beta_F, S_F\) given by
\[
S_F = S, \quad \alpha_F = m \cdot (1 \otimes a)(S \otimes 1) F^{-1}, \quad \beta_F = m \cdot (1 \otimes \beta)(1 \otimes S) F,
\]
is also a quasi-Hopf algebra. Throughout, the element \(F\) is referred to as a twistor.

**Definition 2**: A quasi-Hopf algebra \((A, \Delta, \epsilon, \Phi)\) is called quasi-triangular if there exists an invertible element \(R \in A \otimes A\) such that
\[
\Delta^T(a) R = R \Delta(a), \quad \forall a \in A,
\]
\[
(\Delta \otimes 1) R = \Phi_{231}^{-1} R_{13} \Phi_{132} R_{23} \Phi_{123}^{-1},
\]
\[
(1 \otimes \Delta) R = \Phi_{312} R_{13} \Phi_{213}^{-1} R_{12} \Phi_{123}.
\]
We refer to \(R\) as the universal R-matrix.

Throughout, \(\Delta^T = T \cdot \Delta\) with \(T\) being the twist map which is defined by
\[
T(a \otimes b) = b \otimes a;
\]
and \(\Phi_{132} \ etc\) are derived from \(\Phi \equiv \Phi_{123}\) with the help of \(T\)
\[
\Phi_{132} = (1 \otimes T) \Phi_{123},
\]
\[
\Phi_{312} = (T \otimes 1) \Phi_{132} = (T \otimes 1)(1 \otimes T) \Phi_{123},
\]
\[
\Phi_{231}^{-1} = (1 \otimes T) \Phi_{213}^{-1} = (1 \otimes T)(T \otimes 1) \Phi_{123}^{-1},
\]
and so on.

It is easily shown that the properties (2.16)-(2.18) imply the Yang-Baxter type equation,
\[
R_{12} \Phi_{231}^{-1} R_{13} \Phi_{132} R_{23} \Phi_{123}^{-1} = \Phi_{321}^{-1} R_{23} \Phi_{312} R_{13} \Phi_{213}^{-1} R_{12},
\]
which is referred to as the quasi-Yang-Baxter equation.
Theorem 2: Denoting by the set \((A, \Delta, \epsilon, \Phi, R)\) a quasi-triangular quasi-Hopf algebra, then \((A, \Delta_F, \epsilon, \Phi_F, R_F)\) is also a quasi-triangular quasi-Hopf algebra, with the choice of \(R_F\) given by

\[
R_F = F^T R F^{-1}, \quad (2.21)
\]

where \(F^T = T \cdot F \equiv F_{21}\). Here \(\Delta_F\) and \(\Phi_F\) are given by \((2.13)\) and \((2.14)\), respectively.

Let us specify some notations, where we adopt a summation convention over all repeated indices. Throughout the paper,

\[
\Phi = X_i \otimes Y_i \otimes Z_i, \quad \Phi^{-1} = \bar{X}_i \otimes \bar{Y}_i \otimes \bar{Z}_i,
\]

\[
F = f_i \otimes f^i, \quad F^{-1} = \bar{f}_i \otimes \bar{f}^i,
\]

\[
R = a_\nu \otimes b_\nu, \quad R^{-1} = c_\nu \otimes d_\nu,
\]

\[
(1 \otimes \Delta)\Delta(a) = \sum a_{(1)} \otimes \Delta(a_{(2)}) = \sum a^R_{(1)} \otimes a^R_{(2)} \otimes a^R_{(3)},
\]

\[
(\Delta \otimes 1)\Delta(a) = \sum \Delta(a_{(1)}) \otimes a_{(2)} = \sum a^L_{(1)} \otimes a^L_{(2)} \otimes a^L_{(3)},
\]

\[
(\Phi^{-1} \otimes I)(\Delta \otimes I \otimes I)\Phi = A_i \otimes B_i \otimes C_i \otimes D_i,
\]

\[
(\Delta \otimes I \otimes I)\Phi^{-1}(\Phi \otimes I) = K_i \otimes L_i \otimes M_i \otimes N_i. \quad (2.22)
\]

A important type of twistor is that due to Drinfeld [3]. For any quasi-Hopf algebra \(A\) observe that the actions

\[
(S \otimes S) \cdot \Delta^T, \quad \Delta^T \cdot S^{-1}
\]

both determine algebra anti-homomorphisms. It follows that

\[
\Delta' \equiv (S \otimes S) \cdot \Delta^T \cdot S^{-1}
\]

gives rise to an algebra homomorphism and thus a co-product action on \(A\). Drinfeld showed that the actions \(\Delta\) and \(\Delta'\) are related by a twistor; i.e.

\[
\Delta(a) = F^{-1} \left( (S \otimes S) \Delta^T (S^{-1}(a)) \right) F \quad \forall a \in A
\]

where

\[
F = (S \otimes S) \Delta^T(X_i) \gamma \Delta(Y_i \beta S(Z_i))
\]

and

\[
\gamma = S(B_i) \alpha C_i \otimes S(A_i) \alpha D_i. \quad (2.23)
\]

It is also useful to define

\[
\delta = K_i \beta S(N_i) \otimes L_i \beta S(M_i). \quad (2.24)
\]
Then the following relations can be shown to hold

$$\Delta(\alpha) = F^{-1}\gamma, \quad \Delta(\beta) = \delta F.$$  

A quasi-Hopf algebra is said to be of trace type if there exists an invertible element $u \in A$ such that

$$S^2(a) = uau^{-1}, \quad \forall a \in A. \quad (2.25)$$

In the case $A$ is quasi-triangular with R-matrix as in (2.22) we have [1]

**Theorem 3**: The operator defined by

$$u = S(Y_i\beta S(Z_i)) S(\beta_\nu) a_\nu X_i \quad (2.26)$$

satisfies (2.25). Moreover the inverse is given by

$$u^{-1} = S^{-1}(X_i) S^{-1}(\alpha d_\nu)c_\nu Y_i \beta S(Z_i). \quad (2.27)$$

An important relation satisfied by $u$ is

$$S(\alpha)u = S(b_\nu)\alpha a_\nu \quad (2.28)$$

which we will need later.

The significance of trace type quasi-Hopf algebras is that they afford a systematic means to construct Casimir invariants. We have the following result from [14].

**Theorem 4**: Let $\pi$ be the representation afforded by the finite-dimensional $A$-module $V$. Suppose $\eta = \mu_i \otimes \nu_i \otimes \rho_i \in A \otimes \text{End} V \otimes A$ obeys

$$(1 \otimes \pi \otimes 1)(1 \otimes \Delta)\Delta(a) \cdot \eta = \eta \cdot (1 \otimes \pi \otimes 1)(1 \otimes \Delta)\Delta(a), \quad \forall a \in A, \quad (2.29)$$

then

$$\text{tr} (\nu_i \pi (\beta S(\rho_i) S(\alpha)u)) \mu_i \quad (2.30)$$

is a central element. Similarly if $\bar{\eta} = \bar{\mu}_i \otimes \bar{\nu}_i \otimes \bar{\rho}_i \in A \otimes \text{End} V \otimes A$ satisfies

$$\bar{\eta} \cdot (1 \otimes \pi \otimes 1)(\Delta \otimes 1)\Delta(a) = (1 \otimes \pi \otimes 1)(\Delta \otimes 1)\Delta(a) \cdot \bar{\eta}, \quad \forall a \in A \quad (2.31)$$

then

$$\sum \text{tr} \left( \bar{\nu}_i \pi \left( u^{-1} S(\beta) S(\bar{\mu}_i) \alpha \bar{\nu}_i \right) \right) \bar{\rho}_i \quad (2.32)$$

is a central element.

As a consequence of the above we have
Corollary 1: Suppose $\omega = \sum \omega_i \otimes \Omega^i \in A \otimes \text{End}V$ satisfies

$$(1 \otimes \pi)\Delta(a) \cdot \omega = \omega \cdot (1 \otimes \pi)\Delta(a), \quad \forall a \in A.$$  

Then (2.29) implies that

$$\tau(\omega) = \text{tr} \left( \Omega^i \pi \left( Y_{k_1} \beta S(Z_j Z_k) S(\alpha) u \bar{Y}_j \right) \right) \bar{X}_j \omega_i X_k$$

is a central element.

For an $(n + 1)$-fold tensor product space and $\omega = \sum \omega_i \otimes \Omega^i \in A^\otimes n \otimes \text{End}V$ we define

$$\tau_n(\omega) = \text{tr} \left( \Omega^i \pi \left( Y_{k_1} \beta S(Z_j Z_k) S(\alpha) u \bar{Y}_j \right) \right) \Delta^{(n-1)}(\bar{X}_j) \omega_i \Delta^{(n-1)}(X_k).$$

### 3 Representations of the braid group

Given any representation $\pi$ of a quasi-Hopf algebra $A$ we set

$$\tilde{R} = P.(\pi \otimes \pi)R$$

and

$$\Phi_i = (\Delta^{(i-2)} \otimes I \otimes I) \Phi.$$  

In terms of $\tilde{R}$ the quasi-Yang-Baxter equation may be written

$$\Phi \tilde{R}_{23} \Phi^{-1} \tilde{R}_{12} \Phi \tilde{R}_{23} \Phi^{-1} = \tilde{R}_{12} \Phi \tilde{R}_{23} \Phi^{-1} \tilde{R}_{12}$$

where throughout we use the same symbols $\Phi$ and $\Phi_i$ for both the algebraic objects and their matrix representatives.

**Theorem 5** Define $n$ operators on the $(n + 1)$-fold tensor product space by

$$\sigma_i = \Phi_i \tilde{R}_{i(i+1)} \Phi_i^{-1}, \quad i = 1, 2, ..., n$$

These give rise to a representation of the braid group $B_n$ by satisfying the defining relations

$$\sigma_i \sigma_j = \sigma_j \sigma_i, \quad j \neq i \pm 1$$

$$\sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1}.$$  

The above result was given in [1]. Here we want to present a detailed proof.
First we establish that the braid generators (3.3) are invariant with respect to the co-product action $\Delta^{(n)}$ of $A$; i.e

$$[\sigma_i, \Delta^{(n)}(a)] = 0 \quad \forall a \in A. \quad (3.6)$$

It is clear from the definition (3.1) that

$$[\check{R}, \Delta(a)] = 0 \quad \forall a \in A$$

which immediately implies that

$$[\sigma_1, \Delta^{(n)}(a)] = 0 \quad \forall a \in A.$$

Next consider

$$\sigma_2 \Delta^{(j)}(a) = \Phi \hat{R}_{23} \Phi^{-1} (\Delta \otimes I^{\otimes(j-1)}) \Delta^{(j-1)}(a)$$

$$= \Phi \hat{R}_{23} (I \otimes \Delta \otimes I^{\otimes(j-2)}) \Delta^{(j-1)}(a) \Phi^{-1}$$

$$= \Phi (I \otimes \Delta \otimes I^{\otimes(j-2)}) \Delta^{(j-1)}(a) \hat{R}_{23} \Phi^{-1}$$

$$= (\Delta \otimes I^{\otimes(j-1)}) \Delta^{(j-1)}(a) \Phi \hat{R}_{23} \Phi^{-1}$$

$$= \Delta^{(j)}(a) \sigma_2 \quad (3.7)$$

Observing that the action (2.11) enjoys the property

$$\Delta^{(i)} \cdot \Delta^{(j)} = \Delta^{(i+j)}.$$

and applying $\Delta^{(k)} \otimes I^{\otimes j}$ to (3.7) now yields (3.6) by choosing $k = i - 2$, $j = n - i - 2$.

Since $\hat{R}$ commutes with the co-product action we immediately deduce for $i > 1$

$$\sigma_1 \sigma_i = \hat{R}_{12} \Phi \hat{R}_{(i+1)} \Phi^{-1}$$

$$= \sigma_i \sigma_1.$$
Applying $\Delta^{(k)} \otimes I \otimes I$ to (3.4) yields (3.5) for $i \geq 2$ by choosing $k = i - 2, l = j - i + 2$.

In order to show that (3.5) is satisfied we see from (3.2) that
\[ \sigma_1 \sigma_2 \sigma_1 = \sigma_2 \sigma_1 \sigma_2 \]
is certainly true. Now through (3.2), the invariance of $\bar{R}$ and repeated use of the pentagonal relation (2.2) we find
\[
\begin{align*}
\sigma_2 \sigma_3 \sigma_2 &= \Phi_2 \bar{R}_{23} \Phi_2^{-1} \Phi_3 \bar{R}_{34} \Phi_3^{-1} \Phi_2 \bar{R}_{23} \Phi_2^{-1} \\
&= \Phi_2 \bar{R}_{23} \Phi_2^{-1} \Phi_3 (I \otimes I \otimes \Delta) \Phi \bar{R}_{34} (I \otimes I \otimes \Delta) \Phi^{-1} \Phi_3^{-1} \Phi_2 \bar{R}_{23} \Phi_2^{-1} \\
&= \Phi_2 \bar{R}_{23} (I \otimes \Delta \otimes I) \Phi (I \otimes \Phi) \bar{R}_{34} (I \otimes \Phi^{-1}) (I \otimes \Delta \otimes I) \Phi^{-1} \Phi_2 \bar{R}_{23} \Phi_2^{-1} \\
&= \Phi_2 (I \otimes \Delta \otimes I) \Phi (I \otimes \Phi) \bar{R}_{23} (I \otimes \Phi) \bar{R}_{34} (I \otimes \Phi^{-1}) \bar{R}_{23} (I \otimes \Phi^{-1}) (I \otimes \Delta \otimes I) \Phi^{-1} \Phi_2 \bar{R}_{23} \Phi_2^{-1} \\
&= \Phi_3 (I \otimes I \otimes \Delta) \Phi \bar{R}_{34} (I \otimes \Phi^{-1}) \bar{R}_{23} (I \otimes \Phi) \bar{R}_{34} (I \otimes I \otimes \Delta) \Phi^{-1} \Phi_3^{-1} \\
&= \Phi_3 \bar{R}_{34} \Phi_3^{-1} \Phi_2 (I \otimes \Delta \otimes I) \Phi \bar{R}_{23} (I \otimes \Delta \otimes I) \Phi^{-1} \Phi_2^{-1} \Phi_3 \bar{R}_{23} \Phi_3^{-1} \\
&= \Phi_3 \bar{R}_{34} \Phi_3^{-1} \Phi_2 \bar{R}_{23} \Phi_2^{-1} \Phi_3 \bar{R}_{34} \Phi_3^{-1} \\
&= \sigma_3 \sigma_2 \sigma_2
\end{align*}
\]
Finally, acting $\Delta^{(i-2)} \otimes I \otimes I$ on (3.9) above yields
\[ \sigma_i \sigma_{i+1} \sigma_i = \sigma_{i+1} \sigma_i \sigma_{i+1} \]

4 Link Polynomials from Ribbon Quasi-Hopf Algebras

In [1] the following definition was proposed for the ribbon quasi-Hopf algebras.

**Definition 3** Let $A$ be a quasi-triangular quasi-Hopf algebra. We say that $A$ is a ribbon quasi-Hopf algebra if there exists a central element $v \in A$ such that
\begin{enumerate}
\item $v^2 = uS(u)$
\item $S(v) = v$
\item $\epsilon(v) = 1$
\item $\Delta(uv^{-1}) = \mathcal{F}^{-1}(S \otimes S) \mathcal{F}_{21} \cdot uv^{-1} \otimes uv^{-1}$
\end{enumerate}
where $F$ is the Drinfeld twist discussed earlier.

Given a ribbon quasi-Hopf algebra, a prescription was also provided in [1] to define a Markov trace on the braid group representation which in turn may be used to compute link polynomials in the usual way. From here on we will omit the symbol $\pi$ denoting the representation for ease of notation.

**Theorem 6** Let $\Psi$ be a word in the braid generators (3.3) for a fixed finite dimensional irreducible representation of a ribbon Hopf-algebra $A$. Then a Markov trace $\theta_n$ on the $(n+1)$-fold tensor product space may be defined by

$$
\theta_n(\Psi) = \text{tr} \left( \Psi \Delta^{(n-1)}(\beta S(\alpha)uv^{-1}) \right)
$$

which satisfies the Markov properties

1. $\theta_n(\Psi_1 \Psi_2) = \theta_n(\Psi_2 \Psi_1)$ \quad $\forall \Psi_1, \Psi_2 \in B_n$
2. $\theta_n(\Psi \sigma^{\pm 1}) = z^{\pm} \theta_{n-1}(\Psi)$ \quad $\forall \Psi \in B_{n-1} \subset B_n$

where $z^{\pm}$ are the eigenvalues of the central operators $v^{\mp 1}$ in the representation $\pi$.

The importance of the Markov trace is that from it one can define a link polynomial $L(\hat{\Psi})$ through

$$
L(\hat{\Psi}) = (z^+ z^-)^{n/2} \left( \frac{z^-}{z^+} \right)^{\epsilon(\Psi)/2} \theta(\Psi), \quad \theta \in B_n
$$

(4.1)

where $\epsilon(\Psi)$ is the sum of the exponents of the $\sigma_i$’s appearing in $\Psi$. The functional $L(\hat{\Psi})$ enjoys the following properties:

1. $L(\hat{\Psi} \eta) = L(\eta \hat{\Psi})$, $\forall \Psi, \eta \in B_M$;
2. $L(\hat{\Psi} \sigma^{\pm 1}_{n-1}) = L(\hat{\Psi})$, $\forall \Psi \in B_{n-1} \subset B_n$

and is an invariant of ambient isotopy.

The first Markov property follows easily from the invariance of the braid generators $\sigma^{\pm 1}$ and the cyclic rule of traces. To establish the second Markov property requires some work and was stated in [1] without proof. Here we provide the details.

Before proceeding, we need to determine the co-product action of the element $S(\alpha)uv^{-1}$. Using the Drinfeld twistor we find

$$
\Delta (S(\alpha)) = F^{-1} \left( (S \otimes S) \Delta^{T}(\alpha) \right) F
= F^{-1} \left( (S \otimes S)(F_{21}^{-1} \gamma_{21}) \right) F
= F^{-1}(S \otimes S) \gamma_{21}.(S \otimes S)F_{21}^{-1}.F
$$
Now through using (2.23) and definition 3 we find that
\[
\Delta \left(S(\alpha)uv^{-1}\right) = \mathcal{F}^{-1} \left(S(D_i)S(\alpha)uv^{-1}A_i \otimes S(C_i)S(\alpha)uv^{-1}B_i\right), \tag{4.2}
\]

We will also need the following result

**Lemma 1** Let \( C \in \text{End}(V \otimes V) \) be any invariant operator; i.e
\[
[C, \Delta(a)] = 0 \quad \forall a \in A.
\]

Then
\[
\left(A_i \otimes B_i\right) C \left(K_j \beta S(D_iN_i) \otimes L_j \beta S(C_iM_i)\right) = \left(\bar{X}_j \otimes \bar{Y}_j\right) C \left(X_i \beta \otimes Y_i \beta S(\bar{Z}_jZ_i)\right).
\]

The above result follows directly from the definitions (2.22). We may now see that
\[
\theta_n(\Psi) = \text{tr} \left(\Psi \Delta^{(n)}(\beta S(\alpha)uv^{-1})\right)
\]
\[
= \text{tr} \left(\Psi \Delta^{(n-1)}(\beta S(\alpha)uv^{-1}A_i) \otimes S(C_i)S(\alpha)uv^{-1}B_i\right)
\]
\[
= \text{tr} \left(\Psi \Delta^{(n-1)}(K_j \beta S(N_j)S(D_i)S(\alpha)uv^{-1}A_i) \otimes L_j \beta S(M_j)S(C_i)S(\alpha)uv^{-1}B_i\right)
\]
\[
= \text{tr} \left(\Psi \Delta^{(n-1)}(X_i \beta \otimes Y_i \beta S(Z_i)S(\bar{Z}_j)S(\alpha)uv^{-1}\bar{Y}_j\right)
\]
\[
= \theta_{n-1}(\tau_n(\Psi)) \tag{4.3}
\]

where the element \( u \) in the definition (2.35) has now been replaced by \( uv^{-1} \). It is apparent also from (2.35) that for \( \Psi \in B_{n-1} \) then
\[
\tau_n(\Psi \sigma_n^{\pm 1}) = \Psi \tau_n(\sigma_n^{\pm 1})
\]

To evaluate \( \tau_n(\sigma_n^{\pm 1}) \) we can appeal to the pentagonal relation (2.2) to find that
\[
\Phi_n^{-1} \sigma_n^{\pm 1} \Phi_n
\]
\[
= \Phi_n^{-1} \Phi_n \bar{R}_{n(n+1)}^{\pm 1} \Phi_n \Phi_n^{-1}
\]
\[
= I^{(n-2)} \otimes \left((I \otimes I \otimes \Delta)\Phi.(I \otimes \Phi^{-1})(I \otimes \Delta \otimes I)\Phi^{-1}.(I \otimes \bar{R}_{n+1}^{\pm 1} \otimes I)\right)
\]
\[
\quad \cdot (I \otimes \Delta \otimes I)\Phi.(I \otimes \Phi)(I \otimes I \otimes \Delta)\Phi^{-1}
\]
\[
= I^{(n-2)} \otimes \left((I \otimes I \otimes \Delta)\Phi.(I \otimes \Phi^{-1})(I \otimes \bar{R}_{n+1}^{\pm 1} \otimes I)(I \otimes \Phi)(I \otimes I \otimes \Delta)\Phi^{-1}\right)
\]

which, upon using (2.5, 2.6, 2.10), leads us to conclude that
\[
\tau_n(\sigma_n^{\pm 1}) = I^{n(n-1)} \otimes \tau(\bar{R}^{\pm 1}).
\]
An algebraic exercise shows that
\[
\tau(\tilde{R}) = \tilde{X}_j b_v Y_i \beta S(Z_i) S(\tilde{Z}_j) S(\alpha) u v^{-1} \tilde{Y}_j a_v X_l,
\]
\[
\tau(\tilde{R}^{-1}) = X_j c_v Y_k \beta S(Z_k) S(\tilde{Z}_j) S(\alpha) u v^{-1} \tilde{Y}_j d_v X_k
\]
and hence we can conclude that \( z^{\pm} \) are given by the eigenvalues of the central operators \( v^{\pm} \) if we can show that the following relations hold.

**Lemma 2**
\[
\tilde{X}_j b_v Y_i \beta S(Z_i) S(\tilde{Z}_j) S(\alpha) u \tilde{Y}_j a_v X_l = I,
\]
\[
\tilde{X}_j c_v Y_k \beta S(Z_k) S(\tilde{Z}_j) S(\alpha) u \tilde{Y}_j d_v X_k = v^2.
\]

Through use of (4.2) we obtain
\[
I = \tilde{X}_i \beta S(\tilde{Y}_i) \alpha \tilde{Z}_i
\]
\[
= \tilde{X}_i \beta S(\tilde{Y}_i) S(d_v) S(b_\mu) \alpha a_\mu c_v \tilde{Z}_i
\]
\[
= \tilde{X}_i \beta S(\tilde{Y}_i) S(d_v) S(\alpha) u c_v \tilde{Z}_i
\]
\[
= \tilde{X}_i \beta S(\tilde{Y}_i) S(d_v) S(\alpha) S^2(c_v) S^2(\tilde{Z}_i) u.
\]

From eq. (2.18) we see that
\[
\mathcal{R}_4^{-1} \Phi_{31}^{-1} (I \otimes \Delta) \mathcal{R} = \Phi_{21}^{-1} \mathcal{R}_{12} \Phi_{13}
\]
which expressed in terms of the tensor components reads
\[
c_v \tilde{Z}_j a_l \otimes \tilde{X}_j b_l^{(1)} \otimes d_v \tilde{Y}_j b_l^{(2)} = \tilde{Y}_j a_v X_l \otimes \tilde{X}_j b_v Y_l \otimes \tilde{Z}_j Z_l.
\]

We can now write
\[
\tilde{X}_j b_v Y_i \beta S(Z_i) S(\tilde{Z}_j) S(\alpha) u \tilde{Y}_j a_v X_l
\]
\[
= \tilde{X}_j b_l^{(1)} \beta S(b_l^{(2)}) S(\tilde{Y}_j) S(d_v) S(\alpha) u c_v \tilde{Z}_j a_l
\]
\[
= \epsilon(b_l) \tilde{X}_j \beta S(\tilde{Y}_j) S(d_v) S(\alpha) u c_v \tilde{Z}_j a_l
\]
\[
= \tilde{X}_i \beta S(\tilde{Y}_i) S(d_v) S(\alpha) S^2(c_v) S^2(\tilde{Z}_i) u
\]
\[
= I.
\]

Next we see that
\[
u = S \left( \tilde{X}_i \beta S(\tilde{Y}_i) \alpha \tilde{Z}_i \right) u
\]
\[
= S(\tilde{Z}_i) S(\alpha) S^2(\tilde{Y}_i) S(\beta) S(\tilde{X}_i) u
\]
\[
= S(\tilde{Z}_i) S(\alpha) u \tilde{Y}_i S^{-1}(\beta) S^{-1}(\tilde{X}_i)
\]
\[
= S(\tilde{Z}_i) S(b_v) \alpha a_v \tilde{Y}_i S^{-1}(\beta) S^{-1}(\tilde{X}_i)
\]

(4.6)
where in the last step we have used eq. (2.28). Consequently
\[ S(u) = \bar{X}_i \beta S(\bar{Y}_i) S(a_{\nu}) S(a) S^2(b_{\nu}) S^2(\bar{Z}_i). \]

From eq. (2.17) we have
\[ \mathcal{R}_{23} \Phi^{-1} \left( \Delta \otimes I \right) \mathcal{R}^{-1} = \Phi^{-1} \mathcal{R}_{13}^{-1} \Phi_{231} \]
which we may express as
\[ \bar{X}_j c_{\nu}^{(1)} \otimes a_{\mu} Y_{j}^{(2)} \otimes b_{\mu} \bar{Z}_j d_{\nu} = \bar{X}_j c_{\nu} Y_k \otimes \bar{Z}_j Z_k \otimes \bar{Y}_j d_{\nu} X_k. \]

This relation leads us to deduce that
\[ \bar{X}_j c_{\nu} \beta S(Z_k) S(\bar{Z}_j) S(\alpha) u \bar{Y}_j d_{\nu} X_k \]
\[ = \bar{X}_j c_{\nu}^{(1)} \beta S(c_{\nu}^{(2)}) S(\bar{Y}_j) S(a_{\mu}) S(\alpha) u b_{\mu} \bar{Z}_j d_{\nu} \]
\[ = \bar{X}_j \beta S(\bar{Y}_j) S(\alpha) S^2(b_{\mu}) S^2(\bar{Z}_j) u \]
\[ = S(u) u \]
\[ = v^2 \] (4.7)

which proves lemma 2 and completes the proof of Theorem 6.

5 Twisting Invariance of the Markov trace

Now we are in a position to show twisting invariance of the link polynomials. Let us begin with the following result.

Proposition 1 Every twisted ribbon quasi-Hopf algebra is again a ribbon quasi-Hopf algebra.

Recall from definition 3 that the first three conditios of a ribbon quasi-Hopf algebra are properties of the algebra structure rather than the co-algebra. Thus, to this end we need only show that if
\[ \Delta(uv^{-1}) = \mathcal{F}^{-1}(S \otimes S) \mathcal{F}_{21}. uv^{-1} \otimes uv^{-1} \]
then
\[ \Delta_F(uv^{-1}) = \mathcal{F}_F^{-1}(S \otimes S)(\mathcal{F}_F)_{21}. uv^{-1} \otimes uv^{-1} \]
where \( \mathcal{F}_F \) denotes the Drinfeld twistor for the twisted quasi-Hopf algebra. Recalling that the Drinfeld twist \( \mathcal{F} \) is determined by
\[ \mathcal{F} \Delta(a) \mathcal{F}^{-1} = (S \otimes S) \left( \Delta^T \left( S^{-1}(a) \right) \right) \quad \forall a \in A \]
shows that
\[
F \Delta(a) F^{-1} = \Delta_F(a)
\]
\[
= F_F^{-1} \left( (S \otimes S) \Delta_F^T \left( S^{-1}(a) \right) \right) F_F
\]
\[
= F_F^{-1} \left( (S \otimes S) \left( F_{21} \Delta^T \left( S^{-1}(a) \right) F_{21}^{-1} \right) \right) F_F
\]
\[
= F_F^{-1} \left( (S \otimes S) F_{21}^{-1} . (S \otimes S) \Delta \left( S^{-1}(a) \right) . (S \otimes S) F_{21} \right) F_F
\]
\[
= F_F^{-1} (S \otimes S) F_{21}^{-1} . F \Delta(a) F^{-1} . (S \otimes S) F_{21} F_F
\]
which leads us to
\[
F_F = (S \otimes S) F_{21}^{-1} . F F^{-1}.
\]
Now we observe that
\[
F_F^{-1} (S \otimes S) (F_F)_{21} . uv^{-1} \otimes uv^{-1}
\]
\[
= F F^{-1} (S \otimes S) F_{21} . (S \otimes S) \left( (S \otimes S) F^{-1} . (F_F^{-1})_{21} \right) uv^{-1} \otimes uv^{-1}
\]
\[
= F F^{-1} (S \otimes S) F_{21} . (S^2 \otimes S^2) F^{-1} . uv^{-1} \otimes uv^{-1}
\]
\[
= F F^{-1} (S \otimes S) F_{21} . uv^{-1} \otimes uv^{-1} . F^{-1}
\]
\[
= F \Delta(uv^{-1}) F^{-1}
\]
\[
= \Delta_F(uv^{-1})
\]
thus establishing that the twisted ribbon quasi-Hopf algebra is also of ribbon type.

By induction the co-product action on the \((n + 1)\)-fold space assumes the form
\[
\Delta^{(n)}_F (a) = \chi_n \Delta^{(n)} \chi^{-1}_n
\]
where
\[
\chi_n = F_{12} . (\Delta \otimes I) F_{12} . (\Delta^2 \otimes I) F_{12} . . . (\Delta^{(n-1)} \otimes I) F.
\]
Consider next
\[
\chi_n \sigma_i \chi_n^{-1} = F_{12} (\Delta \otimes I) F_{12} . (\Delta^2 \otimes I) F_{12} . . . (\Delta^{(n-1)} \otimes I) F \sigma_i
\]
\[
(\Delta^{(n-1)} \otimes I) F^{-1} . . . (\Delta \otimes I) F_{12}^{-1} . F_{12}^{-1}
\]
\[
= F_{12} (\Delta \otimes I) F_{12} . (\Delta^2 \otimes I) F_{12} . . . (\Delta^{(i-1)} \otimes I) F \sigma_i
\]
\[
(\Delta^{(i-1)} \otimes I) F^{-1} . . . (\Delta \otimes I) F_{12}^{-1} . F_{12}^{-1}
\]
\[
= \chi_i \sigma_i \chi_i^{-1}.
\]

We now determine the representations of the braid generators under twisting; i.e.
\[
\sigma_i^F = (\Delta^{(i-2)} \otimes I \otimes I) \Phi_F . \tilde{R}_{i(i+1)} F\Phi^{-1}_F . (\Delta^{(i-2)} \otimes I \otimes I) \Phi^{-1}_F
\]
\[ \chi_{i-2}(\Delta^{(i-2)} \otimes I \otimes I) \left( F_{12}(\Delta \otimes I) F, \Phi(i \otimes \Delta) F^{-1} F_{23}^{-1} \right) \chi_{i-2}^{-1} F_{i(i+1)}^{-1} R_{i(i+1)}^{-1} F_{i(i+1)}^{-1} \]

\[ \chi_{i-2} \Delta^{(i-2)} \left( F_{23}(I \otimes \Delta) F, \Phi^{-1}(\Delta \otimes I) F^{-1} F_{12}^{-1} \right) \chi_{i-2}^{-1} \]

\[ = \chi_i \Delta \Phi. (\Delta^{(i-2)} \otimes \Delta) F^{-1} F_{i(i+1)}^{-1} \chi_{i-2}^{-1} F_{i(i+1)}^{-1} R_{i(i+1)}^{-1} F_{i(i+1)}^{-1} \]

\[ = \chi_i \Delta \Phi. \Delta^{(i-2)} \Phi^{-1} \chi_{i-1}^{-1} \]

\[ = \chi_i \sigma_i \chi_{i-1}^{-1} \]

\[ = \chi_n \sigma_i \chi_{n-1}^{-1} \]

which shows that the representation of the braid generators under twisting are related to those of the untwisted case by a basis transformation. Thus for any word in the generators of the braid group we can write

\[ \Psi^F = \chi_n \Psi \chi_n^{-1} \]

in an obvious notation.

Using the relations (2.15) we may write

\[ \alpha_F = S(\bar{f}_i) \alpha \bar{f}_i, \quad \beta_F = f_i \beta S(f^i) \]

and proceed to calculate

\[ \theta_n^F(\Psi) = \text{tr} \left( \Psi^F \Delta_F^{(n)} \left( \beta_F S(\alpha_F) u w^{-1} \right) \right) \]

\[ = \text{tr} \left( \chi_n \Psi \Delta^{(n)} \left( \beta_F S(\alpha_F) u w^{-1} \right) \chi_n^{-1} \right) \]

\[ = \text{tr} \left( \Psi \Delta^{(n)} \left( f_i \beta S(\bar{f}_i) S(\bar{f}_i^i) S(\alpha) S^2(\bar{f}_j^i) u w^{-1} \right) \right) \]

\[ = \text{tr} \left( \Psi \Delta^{(n)} \left( f_i \beta S(\bar{f}_i^i) \alpha u w^{-1} \bar{f}_j \right) \right) \]

\[ = \text{tr} \left( \Delta^{(n)}(\bar{f}_j) \Psi \Delta^{(n)} \left( f_i \beta S(\bar{f}_i^i) S(\alpha) u w^{-1} \right) \right) \]

\[ = \text{tr} \left( \Psi \Delta^{(n)} \left( \bar{f}_j f_i \beta S(\bar{f}_i^i) S(\alpha) u w^{-1} \right) \right) \]

\[ = \text{tr} \left( \Psi \Delta^{(n)} \left( \beta S(\alpha) u w^{-1} \right) \right) \]

\[ = \theta_n(\Psi) \]

which proves twisting invariance of the Markov trace and consequently the associated link polynomials.
