Abstract
We discuss quantum theory of fields $\phi$ defined on a $(d+1)$-dimensional manifold $M$ with a boundary $B$. The free action $W_0(\phi)$ which is a bilinear form in $\phi$ defines the Gaussian measure with a covariance (Green function) $G$. We discuss a relation between the quantum field theory with a fixed boundary condition $\Phi$ and the theory defined by the Green function $G$. It is shown that the latter results by an average over $\Phi$ of the first. The QFT in AntiDeSitter space is treated as an example. It is shown that quantum fields on the boundary are more regular than the ones on AntiDeSitter space.

1 Introduction
Quantum field theory (QFT) can be defined by a functional integral

$$d\mu(\phi) = D\phi \exp(-W(\phi))$$

(1)

where $W$ is the classical action. From the point of view of formal properties (translational invariance) of such a functional integral it should not matter whether we write in it $\phi$ or $\phi + \phi_0$. However, if the action is defined on a manifold with a boundary then the dependence on the boundary value of $\phi$ seems to be crucial [1]-[3]. This means that a formal invariance under translations in function space $\phi \rightarrow \phi + \phi_0$ must be broken in the definition of the functional integral in refs.[1]-[3]. Then, the dependence on the boundary value breaks some symmetries present in the classical action $W$. Such an approach to QFT disagrees with the conventional one based on the mode summation [4][5][6][7][8][9][10][11] or perturbation expansion in the number $N$ of components or
in the coupling constant. In this paper we discuss a relation between the two approaches in the framework of the functional integral. In the AntiDeSitter models of refs.[1]-[3] the boundary appears at the spatial infinity and coincides with the (compactified) Minkowski space. In the Euclidean version of the AntiDeSitter space (in the Poincare coordinates) the boundary can be realized as the Euclidean subspace of the hyperbolic space.

We consider a Riemannian manifold $M$ with the boundary $B$. The metric on $M$ is denoted by $G$ and its restriction to $B$ by $g$. We shall denote the coordinates on $M$ by $X$ and their restriction to $B$ by $x$; close to the boundary we write $X = (y,x)$. The action for a minimally coupled massless free scalar field $\phi$ reads

$$W_0(\phi) = \int_M dX \sqrt{G} G^{AB} \partial_A \phi \partial_B \phi \equiv \langle \phi, A\phi \rangle \quad (2)$$

The non-negative bilinear form (2) is defined on a certain domain $D(A)$ of functions. Such a bilinear form determines a self-adjoint operator $A$ [12](the definition of $A$ depends on the choice of $D(A)$) in the Hilbert space of square integrable functions. The free (Euclidean) quantum field $\phi$ is defined by $A^{-1}$ in the sense that the kernel of $A^{-1}$ (the Green function) provides a definition of the two-point correlation function of $\phi$. The Green function $G$ is a solution of the equation

$$-A G = \partial_A G^{AB} \sqrt{G} \partial_B G = \delta \quad (3)$$

where $G = \det G_{AB}$. The solution of eq.(3) is not unique. If $G'$ is another solution of eq.(3) then $G' = G + S$ where $S$ is a solution of the equation

$$AS = 0 \quad (4)$$

We can determine $G$ unambiguously imposing some additional requirements, e.g., requiring that $G = 0$ on the boundary. The various definitions of $G$ correspond to various choices of $D(A)$ in the definition of the bilinear form (2)[12][13].

2 The functional measure

To the free action (2) we add a local interaction $V$. Now, the total action reads

$$W = W_0 + W_I = \int_M dX \sqrt{G} G^{AB} \partial_A \phi \partial_B \phi + \int_M dX \sqrt{G} V(\phi) \quad (5)$$

We can give a mathematical definition of the formal functional measure (1)

$$d\mu_V(\phi) = Z_0^{-1} d\mu_0(\phi) \exp(-W_I) \quad (6)$$

where the Gaussian measure $\mu_0$ is a mathematical realization of the formal integral

$$d\mu_0(\phi) = \mathcal{D}\phi \exp(-W_0)$$
The partition function $Z_0$ in eq.(6)

$$Z_0 = \int d\mu_0 \exp(-W_I)$$

(7)

determines a normalization factor.

We do not discuss in this paper some divergence problems which may arise if $V$ is a local function of $\phi$ and $\mathcal{M}$ has an infinite volume. We may assume that $W_I$ has been properly regularized. We have a suggestion how to construct a regular QFT at the end of this paper.

A functional measure $\mu$ defines a probability distribution of fields $\phi(X)$; more precisely the "smeared out" fields

$$(\phi, f) = \int dX \sqrt{G} \phi(X) f(X).$$

In probability theory (see, e.g., [14][15]) it is convenient to treat the probability measure $\mu$ defined on some sets of random fields $\phi$ as one of many possible realizations of the probability space $(\Omega, \Sigma, P)$. The random field $\phi : \Omega \to R$ (at fixed $X$) is a map from the set $\Omega$ to the set of real numbers such that the two-point correlation function is an average over the "sample paths" $\omega \in \Omega$

$$\langle \phi(X) \phi(Y) \rangle = \int_{\Omega} dP(\omega) \phi_\omega(X) \phi_\omega(Y)$$

where $P$ is a probability measure on the $\sigma$-algebra $\Sigma$ of subsets of $\Omega$. The Gaussian measure gives a realization of the Gaussian random field $\phi_\omega$. It is defined [14][16] by the mean

$$m(X) = \int d\mu(\phi) \phi(X) \equiv \langle \phi(X) \rangle$$

and the covariance

$$G(X,Y) = \int d\mu(\phi) (\phi(X) - \langle \phi(X) \rangle)(\phi(Y) - \langle \phi(Y) \rangle)$$

$$= \langle (\phi(X) - \langle \phi(X) \rangle)(\phi(Y) - \langle \phi(Y) \rangle) \rangle$$

(8)

or by its characteristic function $S$

$$S[i f] = \int d\mu \exp(i \langle \phi, f \rangle) = \exp(i \langle m, f \rangle - \frac{1}{2}(f, G f))$$

Note that if we make a shift in the function space and define $\tilde{\phi} = \phi - m$ then $\tilde{\phi}$ has zero mean. Hence, we could subtract the mean value defining a new Gaussian measure

$$d\tilde{\mu}(\tilde{\phi}) = d\mu(\tilde{\phi} + m)$$
The Gaussian measure is quasiinvariant under a shift $\chi$ if there exists an integrable function $\rho(\phi, \chi)$ such that

$$d\mu(\phi + \chi) = d\mu(\phi)\rho(\phi, \chi)$$  \hspace{1cm} (9)

It is easy to see by a calculation of the characteristic function of both sides of eq.(9) that the measure $\mu$ is quasiinvariant under the shift $\chi$ if \cite{16}

$$\rho(\phi, \chi) = \exp(-\langle \phi, B\chi \rangle - \frac{1}{2}(\chi, C\chi))$$  \hspace{1cm} (10)

and the following equations are satisfied

$$\chi = GB\chi$$  \hspace{1cm} (11)

$$(B\chi, GB\chi) = (\chi, C\chi)$$  \hspace{1cm} (12)

Eqs.(9)-(12) express the formal invariance of the functional measure (1) under translations in the function space. If these conditions are not satisfied then it really does matter what is the shift $\chi$. In some papers on AdS-CFT correspondence \cite{1}-\cite{3},\cite{17}\cite{11} the choice is made $G(X,Y) = G_D(X,Y)$ where $G_D$ is the Dirichlet Green function (vanishing on the boundary) and $\langle \phi(X) \rangle = \phi_0(X)$ where $\phi_0(X)$ is a solution of the equation

$$A\phi_0 = 0$$  \hspace{1cm} (13)

with a fixed boundary condition $\Phi$. We can see that eqs.(11)-(12) cannot be satisfied if $\chi = \phi_0$. Hence, the partition function $Z[\Phi]$ may depend on the boundary value $\Phi$.

In general, choosing in QFT the boundary field $\phi_0 \neq 0$ we break some symmetries of the classical action (5). As an example we could consider the hyperbolic space with the metric

$$ds^2 = y^{-2}(dy^2 + dx_1^2 + \ldots + dx_d^2)$$  \hspace{1cm} (14)

The hyperbolic space (14) has compactified $R^d$ as the boundary \cite{3}. The hyperbolic space can be considered as an Euclidean version of AntiDeSitter space ($AdS_{d+1}$ has compactified Minkowski space as a boundary at conformal infinity \cite{3}). It is also a Euclidean version of DeSitter space. However, the Poincare coordinates (14) are inappropriate for an analytic continuation of quantum fields from the hyperbolic space to DeSitter space (there is also no boundary at conformal infinity of DeSitter space).

The action (5) in the hyperbolic space is invariant under $R^d$ rotations and translations whereas the quantum field theory with a fixed boundary value of $\phi_0$ would not be invariant under these symmetries. The approach to QFT assuming a boundary condition $\Phi$ for the field $\phi_0$ and the Dirichlet boundary condition for the Green function leads to a different quantum field theory than the one
developed in refs. [5][6][7][8]. The latter is determined by the mean $\langle \phi \rangle = 0$ and a choice of the Green function (the free propagator $G$ solving eq.(3)) which does not vanish on the boundary. A possible way to determine the propagator is to construct it for a real time by a mode summation and subsequently to continue analytically the propagator to the imaginary time (for a class of models this is done in [4][6]; the mode summation is also not unique). It seems reasonable to choose the Green function $G$ which has the symmetries of the action $W_0 (1)$ as in [4][5][6][7][11]. Then, the functional measure (6) will have the symmetries of the action (5).

3 An average over the boundary values

After the heuristic discussion in sec.2 of functional integration over fields with a fixed boundary value we prove in this section that the approach starting form the free propagator $G$ is equivalent to a quantization around a classical solution $\phi_0$ with a prescribed boundary value $\Phi$ if subsequently an average over all such boundary values is performed. First, let us assume (in the sense that for the bilinear forms $(f, G f) \geq (f, G_D f)$)

$$G \geq G_D$$

(15)

If the operator $A$ is an elliptic operator then the inequality (15) follows from the maximum principle for elliptic operators [18][19]. We are interested also in operators $A$ with singular or vanishing coefficients which need not be elliptic. It is not clear whether the inequality (15) can be satisfied for such operators. However, the inequality (15) still holds true for the Green functions of singular operators discussed in [20][21] which are expressed by a path integral. The Dirichlet condition imposes a restriction on the class of paths. Hence, the integral over a restricted set of paths is bounded by $G$ in eq.(15).

If the inequality (15) is satisfied then there exists a positive definite bilinear form $G_B$ such that

$$G(X, X') = G_D(X, X') + G_B(X, X')$$

(16)

Clearly on the boundary

$$G(0, x; 0, x') = G_B(0, x; 0, x') \equiv G_E(x, x')$$

(17)

$G_E$ defines a non-negative bilinear form on the set of functions defined on the boundary $B$.

**Theorem 1**

Let $\mu_0$ be the Gaussian measure with the mean zero and the covariance $G$. Assume that $G$ and $G_D$ are real positive definite bilinear forms satisfying the inequality (15). Then, there exist independent Gaussian random fields $\phi_D$ and
\( \phi_B \) with the mean equal zero and the covariance \( \mathcal{G}_D \) and \( \mathcal{G}_B \) resp. such that for any integrable function \( \exp(-W_I)F \)

\[
\int d\mu_0(\phi) \exp(-W_I(\phi))F(\phi) = \int d\mu_D(\phi_D)d\mu_B(\phi_B) \exp(-W_I(\phi_D + \phi_B))F(\phi_D + \phi_B) \tag{18}
\]

In this sense

\[
\phi = \phi_D + \phi_B \tag{19}
\]

The theorem and its proof can be found in [13][14]. It is easy to check eq.(18) for the generating functional ( then \( \exp(-W_I(\phi))F(\phi) = \exp(\phi, J) \)). On a perturbative level the general formula (18) follows from the one for the generating functional. For the general theory of "conditioning" (15) see [13][14]. Eq.(18) is discussed in the lattice approximation in [14] (sec.8.1). Another derivation and a discussion of its relevance to the AdS-CFT correspondence can be found in [22]. The relevance of an average over the boundary values for the Hamiltonian formulation of the quantum field theory is discussed in [23].

Let us note that on a formal level

\[
d\mu_D(\phi_D) = D(\phi_D) \exp(-\frac{1}{2}(\phi_D, A_D\phi_D))
\]

where \( A_D \) is the Laplace-Beltrami operator with the Dirichlet boundary conditions. On a formal level \( A_D\phi_0 = 0 \). Hence, \( d\mu_D(\phi_D + \phi_0) = d\mu_D(\phi_D) \) although strictly speaking the shift of \( \mu_D \) by \( \phi_0 \) does not make sense because \( \phi_0 \) does not vanish on the boundary. We treat the r.h.s. of eq.(18) (before an integration over \( \phi_B \)) as a rigorous version of the QFT shifted by a classical solution. This interpretation is suggested by

**Theorem 2**

Let \( \mathcal{G}_D \) be the Dirichlet Green function of the operator \( A \) (eq.(3)). Let \( \mathcal{G} \) be another real solution of eq.(3) satisfying the inequality (15). Then, there exists a Gaussian random field \( \Phi \) defined on the boundary \( B \) with the mean zero and the covariance \( \mathcal{G}_E \) such that (in the sense of \( L^2(dP) \) integrals [15])

\[
\phi_B(X) = \int_B dx_b \sqrt{g} D(X, x_b) \Phi(x_b) \tag{20}
\]

where \( D(X, x_b) \) is the Green function solving the boundary value problem for eq.(13).

**Proof:** Let us note that \( \mathcal{G}_D \) as well as \( \mathcal{G} \) satisfy the same equation (3). Then, their difference \( \mathcal{G}_B = \mathcal{G} - \mathcal{G}_D \) satisfies the equations

\[
A(X)\mathcal{G}_B(X, X') = A(X')\mathcal{G}_B(X, X') = 0 \tag{21}
\]

and the boundary condition \( \mathcal{G}_B(0, x; 0, x') = \mathcal{G}_E(x, x') \). We can solve eq.(21) with the given boundary condition \( \mathcal{G}_E \)

\[
\mathcal{G}_B(X, X') = \int_B dx_b \sqrt{g} D(X, x_b) \int_B dx'_b \sqrt{g} D(X', x'_b) \mathcal{G}_E(x_b, x'_b) \tag{22}
\]
where \( D \) is the Green function solving the Dirichlet boundary problem for eq.(13). The bilinear form \( G_E \) (17) defines a Gaussian field \( \Phi \) on the probability space \((\Omega, \Sigma, P)\) (see sec.2) with the mean zero and the covariance

\[
\langle \Phi(x)\Phi(x') \rangle = G_E(x, x')
\]  

We define \( \tilde{\phi}_B \) by the r.h.s. of eq.(20) where the integral can be understood in the sense of the \( L^2(dP) \) convergence of the Riemann sums (see, e.g.,[15]). For the proof of the theorem \( \tilde{\phi} = \phi \) it is sufficient to show that the covariance of \( \tilde{\phi}_B \) coincides (as a bilinear form) with \( G_B \). This is a consequence of eq.(22).

Let us note that there exists the Gaussian measure \( \nu_B \) such that

\[
\int d\nu_B(\Phi)\Phi(x)\Phi(x') = G_E(x, x')
\]

\( \nu_B \) can be defined by \( \mu_B \) as

\[ \nu_B = \mu_B \circ T \]

where \( T(\Phi) = \tilde{\phi}_B \) is the one to one map (20) expressing the solution of eq.(13) by its boundary value. We can see that if there is a QFT with a two-point function \( G_B \) non-vanishing on the boundary then there is the unique choice of \( \phi_0 \) solving eq.(13) such that \( \tilde{\phi} = \phi_D + \phi_0 \) is a realization of a random field with the boundary value \( \Phi \). An average over \( \Phi \) leads to the Green function \( G \).

In the example of the hyperbolic space (14) (with the Poincare coordinates) the solution (20) of the Dirichlet boundary problem (13) can be expressed by its boundary value \( \phi_B(y = 0, x) = \Phi(x)[17] \)

\[
\phi_B(X) = y^{\frac{d}{2}} \int dp \exp(ipx)|p|^{\frac{d}{2}} K_{\frac{d}{2}}(|p|y) \tilde{\Phi}(p)
\]  

where \( \tilde{\Phi} \) denotes the Fourier transform of \( \Phi \) and \( K_{\nu} \) is the modified Bessel function of order \( \nu \) [29]. Comparing with eq.(20) we obtain \( X = (y, x) \)

\[
D(X, x') = (2\pi)^{-d} y^{d+1} \int dp \exp(ip(x - x'))|p|^{\frac{d}{2}} K_{\frac{d}{2}}(|p|y)
\]

The two-point function \( G_E \) resulting from the QFT on the hyperbolic space constructed in refs.[4][6][10] is \( G_E = -\ln |x - x'| \) [9][24][26][25]. In the Fourier transforms (up to an inessential normalization) we have ( see the discussion in [4][25][20][21])

\[
\langle \tilde{\Phi}(p)\tilde{\Phi}^*(p') \rangle = \delta(p - p')|p|^{-d}
\]  

We may apply eq.(25) to calculate \( \langle \phi_B(X)\phi_B(X') \rangle \). As a solution of eq.(21) after an analytic continuation to the real time it must coincide with the Hadamard two-point function (vacuum expectation value of an anticommutator of quantum scalar fields) which is usually denoted by \( G^{(1)}(X, X') \) ( the formula for \( G_B \) in the hyperbolic space can be found in [26] and for \( G_D \) in [30] )

\[
G_B(X, X') = \langle \phi_B(X)\phi_B(X') \rangle = (yy')^{\frac{d}{2}} \int dp \exp(ip(x - x')) K_{\frac{d}{2}}(|p|y) K_{\frac{d}{2}}(|p|y')
\]  

\[ (26) \]
4 Non-linear boundary value problem

We can modify the formulation (6)-(13) of QFT on manifolds with a boundary so that the interaction $V(\phi)$ is taken into account already at the classical level. Then, instead of eq.(13) we consider the equation

$$-A\psi = V'(\psi)$$

or in the integral form

$$\psi(X) = \phi_B(X) + \int dX'\sqrt{G_D}(X, X')V'(\psi(X'))$$

where $\phi_B$ is defined in eq.(20). In order to express the functional integral (6) in terms of $\psi$ let us introduce a differential operator

$$A\psi = A + V''(\psi)$$

Define $G_D^\psi$ as the Dirichlet Green function of $A\psi$. Let $\mu_\psi$ be the Gaussian measure with the mean zero and the covariance $G_D^\psi$. Then, the formula (18) reads

$$\int d\mu_0(\phi)\exp(-W_I(\phi))F(\phi) = \int d\mu_0(\phi_B)\exp(W_0(\phi_B) - W(\psi))\det(A_\psi)^{-\frac{1}{2}}\det(A)^{\frac{1}{2}}$$

$$\int d\mu_\psi(\phi_D)\exp\left(-\frac{1}{2}\int dX\sqrt{GV(\phi_D + \psi)} + \frac{1}{2}\int dX\sqrt{GV'(\psi)\phi_D} + \frac{1}{2}\int dX\sqrt{GV} \phi_D + \psi\right)F(\phi_D + \psi)$$

For the proof let us shift variables in eq.(18) and apply eqs.(9)-(12). Then,

$$d\mu_D(\phi_D + \chi)\exp(-\int dX\sqrt{GV(\phi_D + \phi_B + \chi)}F(\phi_D + \phi_B + \chi)$$

$$= d\mu_D(\phi_D))\exp(-\frac{1}{2}\int dX\sqrt{AV}\phi_D + \chi)F(\phi_D + \psi)$$

$$\exp\left(-\frac{1}{2}\int dX\sqrt{GV}'(\psi)\phi_D - \frac{1}{2}\int dX\sqrt{GV} \phi_D + \psi\right)$$

where in the second step we inserted $\chi = \psi - \phi_B$ ($\chi = 0$ on the boundary, hence the shift is admissible). Next, we make use of $A\phi_B = 0$ (then $A\psi = A\chi$), subtract the two first terms of the Taylor expansion of $V(\phi_D + \psi)$ in $\psi$ and apply the formula for a Gaussian integral of an exponential of a quadratic form [16]

$$d\mu_D(\phi_D))\exp\left(-\frac{1}{2}\int dX\sqrt{GV_D}V''(\psi)\phi_D\right) = (\det A_\psi)^{-\frac{1}{2}}d\mu_\psi(\phi_D)$$

The final result is expressed in eq.(30). In this equation $\exp(-W(\psi))$ is the effective action in the tree approximation (discussed by [11]) and $\det A_\psi^{-\frac{1}{2}}$ gives the one-loop approximation to the effective action in QFT with the boundary value $\Phi$. The remaining $d\mu_\psi(\phi_D)$ integral in eq.(30) can be calculated in perturbation expansion. It starts with higher powers $n$ ($n \geq 3$) of $\phi_D$ leading to corrections in higher loops to the effective action.
5 Conclusions

In this section we derive some relations between correlation functions with respect to various measures discussed in earlier sections. Let us define

$$ Z[\Phi] = \exp(-W_0(\phi_B)) \int d\mu_D(\phi_D) \exp(-W_I(\phi_D + \phi_B)) $$  \hspace{1cm} (33)

where $\phi_B$ is defined in eq.(20) with $\Phi$ as a fixed boundary value. The definition (33) is introduced in such a way that it agrees with the large $N$ formula of [2] and the semiclassical calculations of [11] and the ones in eq.(30) (see also a discussion in [27]).

If $Z[\Phi]$ is the generating functional then there exists a field $\mathcal{O}(x)$ such that

$$ Z[\Phi] = \langle \exp(\int_B \mathcal{O}(x)\Phi(x)\sqrt{g}dx) \rangle $$  \hspace{1cm} (34)

Treating $Z[\Phi]$ as the generating functional we can calculate

$$ \frac{\delta}{\delta \phi_B}(X_1)....\frac{\delta}{\delta \phi_B}(X_n) \bigg|_{\phi=0} \equiv \int \frac{d\delta}{\delta \phi_B} \bigg|_{\phi_B=0} \exp(-W_0(\phi_B)) \int d\mu_D(\phi_D) \exp(-W_I(\phi_D + \phi_B)) $$  \hspace{1cm} (35)

where

$$ (D\frac{\delta}{\delta \phi_B})(x) = \int dX \sqrt{G}D(X,x)\frac{\delta}{\delta \phi_B}(X) $$

and

$$ W_0(\phi_B) = \frac{1}{2}(\phi_B,\mathcal{A}\phi_B) $$

We wish to compare these correlation functions with the ones of the bulk field $\phi$ defined by the generating functional

$$ S[J] = \int d\mu_0(\phi) \exp(-W_I(\phi) + (J,\phi)) $$  \hspace{1cm} (36)

Then, the correlation functions can be calculated from the formula

$$ \frac{\delta}{\delta \phi_c}(X_1)....\frac{\delta}{\delta \phi_c}(X_n) \bigg|_{\phi_c=0} \equiv \int \frac{d\delta}{\delta \phi_c} \bigg|_{\phi_c=0} \exp\left(\frac{1}{2}(\phi_c,\mathcal{A}\phi_c)\right) \int d\mu_0(\phi) \exp(-W_I(\phi + \phi_c)) \right) $$  \hspace{1cm} (37)

where on the r.h.s. we have absorbed the linear term of the exponential (36) into a shift of the measure according to eqs.(9)-(10) with $\phi_c = \mathcal{G}J$ and $J = \mathcal{A}\phi_c$. It is clear from eqs.(35) and (37) that a perturbative calculation of $n$-point correlation functions of $\mathcal{O}$ and $\phi$ involves the same graphs and only the propagators are different. The relation between (35) and (37) has been discovered earlier by Duetsch and Rehren [22] (see also [28]). A Hamiltonian derivation of the relation between differentiation with respect to boundary values and sources $J$ can be found in [23].
The field theory in the bulk (6)-(7) is an integral over $Z[\Phi]$

$$Z_0 = \int d\nu_B(\Phi) \exp(W_0(\phi_B))Z[\Phi] \tag{38}$$

We can obtain a connection between some other correlation functions. Generalizing eq.(38) let us define the generating functional $S_D[\phi_B; J]$ in the $\phi_D$ theory shifted by a background field $\phi_B$

$$S_D[\phi_B; J] = \int d\mu_D(\phi_D) \exp(-W_I(\phi_D + \phi_B)) \exp(\int dX \sqrt{G} J\phi_D) \tag{39}$$

Then, from eq.(18) the generating functional for correlation functions of the fields $\phi$ in the model (6) is

$$S[J] = \int d\mu_B(\phi_B) \exp(\int dX \sqrt{G} J\phi_B)S_D[\phi_B; J] \tag{40}$$

It can be seen that $\phi_D$ and $\phi_B$ enter symmetrically in eq.(18). Hence, we may also write

$$S[J] = \int d\mu_D(\phi_D) \exp(\int dX \sqrt{G} J\phi_D)S_B[\phi_D; J] \tag{41}$$

Differentiating both sides of eq.(40) and (41) we obtain a relation between correlation functions of the fields $\phi, \phi_D$ and $\phi_B$. The form of the correlation functions in the model (6) at the boundary points $x_j \in \mathcal{B}$ is a simple consequence of eq.(41)

$$\langle \phi(x_1) \ldots \phi(x_n) \rangle = \int d\mu_D(\phi_D) \int d\nu_B(\Phi) \exp(-W_I(\phi_D + \phi_B))\Phi(x_1) \ldots \Phi(x_n) \tag{42}$$

In particular, if the interaction is concentrated only on the boundary

$$W_I(\phi) = \int_{\mathcal{B}} d\sqrt{gV}(\phi(0,x))$$

then $\phi_D = 0$ in $W_I$ in eq.(42) and the functional integral (42) is the same as in QFT on $\mathcal{B}$ defined by the free field measure $d\nu_B$ with the covariance $G_{E}(x,x')$. In the case of the hyperbolic space this covariance is logarithmic. Hence, ultraviolet problem is the same as for quantum fields in two dimensions.

We think that the QFT theory on a boundary of a curved manifold is interesting for itself because of its remarkable regularity expressed (for the hyperbolic space) in the strong decay (25) in the momentum space. However, the main result of this paper is formulated in eqs.(40)-(42). The formulas connecting the correlation functions of fields in various field theoretic models can shed some light on relations of the AdS-CFT type.

**Acknowledgements**

The author is grateful to an anonymous referee for pointing out ref.[22]. The formulas at the beginning of sec.5 resulted from my effort to derive the results of Duetsch and Rehren in the continuum as the addendum to an earlier version of my paper.
