INTRODUCTION

Intermittent fasting (IF) is a dietary practice in which periods of regular consumption of foods and beverages are interspersed with periods of severe energy restriction or by fasting, typically in 1 to 3 days per week. The objective of fasting is to reduce the total energy value, thus creating a negative energy balance, which results in weight loss.1

The excessive intake of energy is associated with the worldwide increase in the incidence of chronic diseases, including obesity, type II diabetes mellitus...
(DM type II), and metabolic syndrome. Caloric restriction by intermittent fasting increases longevity and reduces the incidence of chronic non-communicable diseases associated with aging, such as obesity, cardiovascular diseases, cancer, renal disease, and diabetes mellitus.12

Fasting is associated with substantial weight loss in short periods of time, around 8 to 12 weeks, accompanied by the control of dyslipidemia, arterial pressure, and changes in body composition.3-5 In addition, increases in insulin sensitivity have also been demonstrated as impacts of intermittent fasting practice.4,5

As stated above, the dietary practice of using intermittent fasting has an impact on the bodyweight of overweight or obese individuals, as well as in reducing the risk of health problems. Therefore, the objective of this study was to verify the relationship of intermittent fasting on the bodyweight of overweight and obese individuals through a systematic review of the literature.

METHODS

We performed a systematic review of randomized clinical trials based on the recommendations of PRISMA (Preferred Reporting Items for Systematic reviews and Meta-Analyses).6

We used the PICO strategy to draw up the main question of the present study, which culminated with the delimitation of the following: Does intermittent fasting have any effect on bodyweight in overweight or obese individuals? Each PICO dimension was equivalent to the following elements: (P) overweight or obese individuals, (I) Intermittent Fasting, (C) calorie-restricted diet, and (O) changes in bodyweight of overweight or obese individuals.

The online search was performed in the PubMed, Science Direct, and Virtual Health Library (VHL) databases, from July to August of 2019, by two authors independently (C.H.R.L and I.K.F.). The connective “and” was used in combination with the Medical Subject Headings (MeSH terms): “Fasting”, “Body Weight”, “Overweight”, and “Obesity”. With their respective analogs in Portuguese and Spanish.

The search for articles in the different databases was performed with the following combinations of descriptors: SEARCH 1: Body composition AND Fasting OR fasting intermittent; SEARCH 2: Obesity OR Adiposity AND Overweight AND Fastin intermittent. The same search combinations were used in Spanish and Portuguese.

The clinical trials searched had a limits of publication date between 2015 and 2019, and had to have been published in English, Portuguese, or Spanish, involving overweight or obese individuals, without restriction of gender, ethnicity, and age over 18 years, available in its entirety, and including intermittent fasting as a dietary practice.

Were excluded studies that included pregnant women, heart disease, publications whose full text was inaccessible, chapters of books, manuals, congress publications, theses, dissertations, articles, reviews, articles outside of the databases, and in vitro studies involving animals. The details of the selection of articles are described in Figure 1.

After defining the inclusion and exclusion criteria, the articles were read and analyzed by two authors independently (C.H.R.L and I.K.F.), initially by reading the title, then the title and abstract, and finally, the full text. In the event of a discrepancy between the evaluators, a third researcher was consulted.

The data extracted from the studies included: author, year of publication, location, sample size, variables analyzed, interventions, and outcomes.

To ensure the methodological quality of this review, we used the Jadad scale,7 employed by two authors independently for qualitative classification.

FIGURE 1. FLOWCHART OF THE IDENTIFICATION, ELIGIBILITY, AND SELECTION OF THE PAPERS INCLUDED IN THE SYSTEMATIC REVIEW.
Scores were assigned to the studies (0-5) based on the following criteria: method of randomization, use of blinding, and description of the proportion of losses during follow-up.

RESULTS

We found 313 articles in the databases searched: ScienceDirect (222), PubMed (48), and BVS (43). After the screening process, 04 articles were considered eligible. The articles included in the last stage of selection were a consensus among researchers. Figure 1 shows the characteristics of the articles included.

The studies were conducted in overweight or obese individuals of both sexes and different locations. All studies used intermittent fasting (IF) as the intervention in comparison with a calorie-restrictive diet (CRD) in the control group. As to the duration of the intervention using intermittent fasting, it ranged from 08 weeks to 04 months.

The papers met most of the criteria established by the tool for evaluation of the methodological quality of randomized clinical trials proposed by Jadad et al. with a score of 3 in all 4 papers, which indicates that the studies had a reliable methodological quality reliable that could be extrapolated to other research scenarios (Table 1).

Table 2 shows the results of four studies that used randomized clinical trials to evaluate the effect of intermittent fasting on the body weight of overweight or obese individuals, using different times of fasting and intervention duration.

Trepanowski et al. conducted a study in Chicago with obese individuals for 24 weeks to compare strategies between the IF and CRD groups. In this protocol, they used fasting for 24 hours on alternate days, in which period of fasting, in the IF group, energy consumption was only 25%, while in the CRD group, it was 75%.

The results of this intervention did not demonstrate significant differences in body weight loss, drawing attention to the figures of such reduction (-7.7kg ±1.0) in both groups after the intervention with fasting.

Corroborating the previous study, a survey carried out in the Colorado region, USA, by Catenacci et al. also revealed no significant effect of fasting on the body weight of overweight or obese individuals in the IF group (-8.2 ± 0.9 kg), when compared to the CRD in this same population (-7.1kg ± 1.0).

The protocol used consisted in providing a diet with a calorie deficit of 400 kcal/day, based on the estimated energy needs of the participants included in the CRD group, whereas for the participants of the IF group the protocol was fasting with total calorie restriction for 24 hours on alternate days.

Two studies assessed the effect of intermittent fasting in overweight or obese individuals comparing IF groups with CRD groups, using different protocols. In both studies, the weight reduction was significant in the IF group in comparison to the CRD group.

In the first study, the protocol consisted of a calorie restriction of 500 kcal/day based on the energy needs in the CRD and IF groups; participants in the IF group were instructed to fast for 18 hours/day for the 24 weeks of intervention. In addition, the participants of the IF group had two meals per day only, while the ones in the CRD group had their six meals regularly. The findings of this research have demonstrated a reduction in body weight of -4.0kg ± 1.0 in the IF group in comparison to -2.0kg ± 1.0 in the CRD group.

In the second study, the protocol was carried out in participants of both sexes, according to the Buchinger method, which consists of fasting from solid foods for 7 consecutive days in the IF group and a balanced diet in the CRD group. In this protocol, the intervention lasted for 4 months. The outcomes of this research revealed a significant impact on weight reduction in the IF group (-3.5 ± 4.5) in comparison to the CRD group (-2.0 ± 4.8).

DISCUSSION

The main difference between the calorie-restrictive diet protocols and the frequency of fasting involves schemes with restriction of calories without the need to eliminate one or more meals during the day. In contrast, intermittent fasting requires deprivation of food on alternate days during the week.

The results of this revision corroborate other studies that evaluated the loss of body weight using intermittent fasting as a strategy. The authors showed that the loss varies from 2.5 to 9.9%, including the loss of associated body fat. These results are consequences of metabolic changes caused by fasting, which lead to an increase in lipolysis, proteolysis, and the depletion of glycogenolysis.

According to Azevedo et al., the metabolic alterations are observed soon after the beginning of the fasting period. Plasma glucose levels fall and remain low during this period; lipolysis, ketogenesis, and gluconeogenesis increase while glycogenolysis decreases.
The increase in lipolysis and fat oxidation provides the substrate for gluconeogenesis and compensates for the decline in carbohydrate oxidation and glycogenolysis. This process also causes a moderate increase in proteolysis and protein oxidation.

Intermittent fasting also negatively regulates the expression in muscle tissue of mTOR, the gene responsible for modulating nutritional signaling, which decreases protein synthesis and increases the expression of carnitine palmitoyltransferase I (CPT-1) in muscle tissue, as well as lipid oxidation. These metabolic processes lead to weight loss, as demonstrated by the results of two studies included in this review, but it is worth noting that these studies followed different protocols; the other two studies included had similar protocols showed no significant results.

Varady et al.4 supports intermittent fasting as an efficient dietary practice that can culminate in health benefits. This conclusion is based on their study on 16 obese individuals submitted to eight weeks of intermittent fasting, consuming 25% of their basal energy needs. The fasting protocol promoted significant weight loss, reduced adipose tissue mass, blood pressure, and heart rate, improved the lipid profile, reduced the total cholesterol and LDL-c, and increased the levels of HDL cholesterol.

This metabolic regulation, according to Santos and Macedo15, can increase the liver production of apolipoprotein A (apo A) and decrease apolipoprotein B (apo B). The production of apo A increases HDL-c since it is its precursor. The increased expression of PPARα is also responsible for the increase in serum HDL. The reduced production of apo B also promotes a decrease in serum levels of VLDL, LDL, and small and dense LDL (sdLDL).

The limitations of this review are related to the profile of the articles included, considering they used different protocols, different ages, and different genres. Another limitation is regarding the sample size of the studies, which were restricted.

The strengths are related to the information that although intermittent fasting is disseminated among the general population as an effective dietary practice for weight loss, randomized clinical trial studies comparing IF are not conclusive in demonstrating better effects for weight loss in relation to calorie-restrictive diets.
CONCLUSION

The results of this systematic review did not provide conclusive evidence of greater benefits from intermittent fasting on the bodyweight of overweight or obese individuals when compared with a diet of calorie restriction in different periods of intervention. Therefore, further interventional studies on intermittent fasting are needed with larger sample sizes and standardization of protocols.

Author’s contributions

The authors Carlos Henrique Ribeiro Lima and Iara Katrynne Fonsêca Oliveira contributed to the writing of the text of the article; the other co-authors contributed to the evaluation and revision of the article.
