ABSTRACT

Objective: The aim of the current study is to evaluate the effect of pterostilbene (PTS), on deranged plasma and tissue glycoprotein components in high-fat diet (HFD) and streptozotocin (STZ)-induced type 2 diabetic mice.

Methods: The experimental duration was 16 weeks. The C57BL6/J mice were fed a normal diet, normal diet with PTS, HFD, and STZ injection (10 th week only), and diabetic mice with PTS for the past 6 weeks.

Results: A significant increase in glycoprotein components such as hexose, hexosamine, fucose, and sialic acid (SA) in plasma was observed in diabetic mice. In hepatic and renal tissues, a significant decrease in SA with an increase in other glycoprotein components was detected in diabetic mice compared with control mice. Oral administration of PTS significantly improved the glycoprotein levels in plasma and tissues of diabetic mice to near normal level.

Conclusion: In this study, we resolved that PTS improves disturbed glycoprotein metabolism in HFD and STZ-induced type 2 diabetic mice.

Keywords: Pterostilbene, High-fat diet, Streptozotocin, Hexosamine, Fucose, Sialic acid.

INTRODUCTION

Diabetes mellitus is a multifaceted disease characterized by unusual metabolism of carbohydrates, lipids, and proteins, and type 2 diabetes mellitus (T2DM) is the most dominant form of diabetes, which presents in more than 90% of diabetic cases [1]. Diabetes has develop one of the most challenging health problems on a global scale. The International Diabetes Federation (IDF) estimated that, in 2017, there were 451 million (age 18–9 years) people with diabetes worldwide and this number was predicted to rise to 693 million by 2045 [2]. Diabetes is now showing an alarming increase in prevalence in developing countries. India alone, the prevalence of diabetes is expected to 79.4 million in 2030, i.e. one-sixth of the world total [3].

Hyperglycemia and insulin deficiency, the hallmarks of diabetes mellitus, alter glycoprotein components in various tissues. Several studies reported that impaired metabolism of glycoproteins plays a major role in the pathogenesis of diabetic complications [4]. Under diabetic conditions, reactive oxygen species is produced mainly through glycation reaction, which occurs in various tissues and may play an important role in the development of diabetic complications [5]. Advanced glycation end-products modify galactose, fucose, and sialic acid (SA) contents of specific cellular glycoproteins [6]. This process leads to long-term damage, dysfunction, and failure of various organs, especially the eyes, kidney, nerves, heart, and blood vessels, and creates a huge economic burden related to the management of diabetic complications [7].

Glycoproteins are conjugated proteins that have one or more covalently connected carbohydrate chains which donate to the structure of extracellular matrix in animal cells. The principle forms of sugar present are hexose, hexosamine, fucose, and SA, which encrypt the diverse biological roles of glycoproteins [8]. Glycoproteins are main components of extracellular matrix, cell membrane, and membranes of the subcellular organelles. They play a vital role in the maintenance of structural integrity of the membrane bilayer. Cell surface glycoproteins have important roles in the transport of vitamins and lipids, in signal transduction as hormone receptors and in immunological specificity [9].

Pterostilbene (PTS) is a naturally derived compound found primarily in blueberries and Pterocarpus marsupium heartwood [10]. Substantial evidence suggests that PTS may have numerous preventive and therapeutic properties in a vast range of human diseases that include neurological, cardiovascular, metabolic, and hematologic disorders. Further benefits of PTS have been reported in preclinical trials, in which PTS was shown to be a potent anticancer agent in several malignancies [11]. PTS is structurally similar to resveratrol, a compound found in red wine that has comparable antioxidant, anti-inflammatory, and anticarcinogenic properties; however, PTS exhibits increased bioavailability due to the presence of two methoxy groups which cause it to exhibit increased lipophilic and oral absorption. In animal studies, PTS was shown to have 80% bioavailability compared to 20% for resveratrol making it potentially advantageous as a therapeutic agent [12].

The present study is aimed to investigate the ameliorative potential of PTS on glucose, insulin, and glycoprotein components (hexose, hexosamine, fucose, and SA) in plasma and tissues (the liver and kidney) of high-fat diet (HFD)/STZ-induced diabetic mice.

METHODS

Experimental animals and animal ethical
Healthy adult male C57BL/6 mice 3 weeks of age were obtained from BioGen Laboratory Animal Facility, Bengaluru, India, and housed in polypolyene cages. The animals were housed in well-ventilated polypolyene cages and controlled environment (temperature 23±2°C, humidity 65–70%, and 12 h light/dark cycle) in the Central Animal House, Department of Experimental Medicine, Rajah Muthiah Medical College, Annamalai University. Animals were maintained under standard conditions with a 12 h light/dark cycle and were provided with...
standard pellet diet and water ad libitum. All studies were conducted in accordance with the National Institute of Health, "guide for the care and use of laboratory animals" and CPCSEA guidelines. The study protocols were approved by the Institutional Animal Ethics Committee of Rajah Muthiah Medical College and Hospital (Reg. No. 160/1999/CPCSEA, Proposal number: 972), Annamalainagar.

**Experimental induction of diabetes**

Diabetes was induced in male C57BL/6j mice by feeding a HFD containing 35% fat (beef tallow mixed with the diet) for 60 days; in addition, streptozotocin (STZ) was injected at a low dose in the 10th week.

**Experimental design**

Test animals were fed initially, before the study, with standard diets for 2 weeks. Then, these mice were assigned to one of the four groups with six mice in each group:

| Group 1 | Mice received standard pellet diet for 16 weeks |
|--------|-----------------------------------------------|
| Group 2 | Mice received PTS (40 mg/kg BW) for 16 weeks   |
| Group 3 | Mice received HFD for 16 weeks and STZ was injected at 10th week |
| Group 4 | Diabetic mice received PTS (40 mg/kg BW) for the last 6 weeks |

**Extraction of glycoproteins**

To 0.1 ml of plasma, 5.0 ml of methanol was added, mixed well, and centrifuged for 10 min at 3000× g. The supernatant was decanted and the precipitate was again washed with 5.0 ml of 95% ethanol and recentrifuged, and the supernatant was decanted to obtain the precipitate of glycoproteins. This was used for the estimation of hexose and hexosamine.

For extraction of glycoproteins from the tissues, a known weight of the tissue was homogenized in 7.0 ml of methanol. The contents were filtered and homogenized with 14.0 ml of chloroform. This was filtered and the residue was successively homogenized in chloroform-methanol (2:1 v/v), and each time, the extract was filtered. The residue (defatted tissues) was obtained and the filtrate was decanted. A weighed amount of defatted tissue was suspended in 3.0 ml of 2 N HCl and heated at 90°C for 4 h. The sample was cooled and neutralized with 3.0 ml of 2 N NaOH. Aliquots from this were used for the estimation of hexose, hexosamine, and SA.

**Determination of glycoproteins levels**

Hexose was estimated by the method of Niebes [13]. The reaction mixture contained 0.5 ml of tissue homogenate/plasma, 0.5 ml of 5% phenol, and 2.5 ml of concentrated HCl. It was boiled for 6 h and neutralized with 6N NaOH. To 0.8 ml of the neutralized sample, add 0.6 ml of acetylaceetone reagent and boiled for 30 min. The mixture was treated with 2.0 ml of Ehrlich’s reagent. The color developed was read at 540 nm colorimetrically.

**Statistical analysis**

The results were expressed as a mean standard deviation for six mice (n=6) in each group. Data were analyzed by one-way analysis of variance followed by Duncan’s multiple range test using SPSS version 17 (SPSS, Chicago, IL). Post hoc testing was performed for intergroup comparisons using the least significant difference test. p<0.05 was considered as statistically significant.

**RESULTS**

Table 1 shows the changes in the levels of hexose, hexosamine, fucose, and SA in plasma of control and experimental mice. There was a significant increase in plasma glycoproteins in HFD/STZ-induced diabetic mice when compared to normal control mice. Administration of PTS to diabetic mice resulted in a significant reduction of glycoproteins in the plasma when compared to diabetic control mice.

The levels of glycoproteins in liver and kidney tissues of control and experimental mice are shown in Tables 2 and 3. The levels of SA were significantly decreased in the tissues of HFD-induced diabetic mice.

| Groups               | Hexose (mg/dl) | Hexosamine (mg/dl) | Fucose (mg/dl) | Sialic acid (mg/dl) |
|----------------------|----------------|-------------------|---------------|---------------------|
| Normal control       | 90.2±6.87      | 69.7±5.30         | 29.3±2.23     | 56.3±4.29           |
| Normal+PTS (40 mg/kg b.w) | 89.4±6.84      | 66.3±5.07         | 29.1±2.23     | 54.4±3.16           |
| HFD+STZ              | 141.3±10.76    | 92.4±7.03         | 48.4±3.68     | 75.4±5.74           |
| HFD+HFD+PTS (40 mg/kg b.w) | 103.2±7.90    | 73.5±6.53         | 33.8±2.59     | 62.3±4.77           |

Values are means±SD for six mice. Values not sharing a common superscript (a, b, and c) differ significantly at p<0.05 (DMRT). PTS: Pterostilbene, HFD: High-fat diet, STZ: Streptozotocin, SD: Standard deviation, DMRT: Duncan’s multiple range test.

| Groups               | Hexose (mg/g) | Hexosamine (mg/g) | Fucose (mg/g) | Sialic acid (mg/g) |
|----------------------|---------------|-------------------|---------------|---------------------|
| Normal control       | 41.6±4.17     | 17.3±1.32         | 15.8±2.08     | 10.4±2.07           |
| Normal+PTS (40 mg/kg b.w) | 38.6±2.95     | 18.8±1.43         | 16.9±2.29     | 10.0±2.07           |
| HFD+STZ              | 58.1±4.42     | 43.4±3.30         | 34.9±2.45     | 84.2±5.32           |
| HFD+HFD+PTS (40 mg/kg b.w) | 45.5±3.50    | 22.3±1.71         | 19.4±1.48     | 73.3±4.77           |

Values are means±SD for six mice. Values not sharing a common superscript (a, b, and c) differ significantly at p<0.05 (DMRT). PTS: Pterostilbene, HFD: High-fat diet, STZ: Streptozotocin, SD: Standard deviation, DMRT: Duncan’s multiple range test.
Table 3: Changes in the levels of renal glycoproteins in normal and experimental mice

| Groups                        | Hexose (mg/g) | Hexosamine (mg/g) | Fucose (mg/g) | Sialic acid (mg/g) |
|-------------------------------|---------------|-------------------|--------------|-------------------|
| Normal control                | 27.8±2.11a    | 14.8±1.12a        | 11.88±0.90b  | 7.82±0.59b        |
| Normal+PTS (40 mg/kg b.w)     | 24.19±1.85a   | 12.61±0.96a       | 11.06±0.84a  | 7.23±0.55a        |
| HFD+STZ                        | 5.23±3.96b    | 27.08±2.06b       | 28.60±2.17b  | 4.78±0.36b        |
| HFD+HFD+PTS (40 mg/kg b.w)    | 32.65±2.50c   | 17.13±1.30c       | 15.82±1.21c  | 6.12±0.46c        |

Values are means±SD for six mice. Values not sharing a common superscript (a, b, c) differ significantly at p<0.05 (DMRT). PTS: Pterostilbene, HFD: High-fat diet, STZ: Streptozotocin, SD: Standard deviation, DMRT: Duncan’s multiple range test.

Histopathological examination of the kidney of diabetic mice revealed morphological changes. The kidney of HFD/STZ-induced mice showed significant vacuolar degeneration, increased protein-bound hexose and hexosamine, and decreased level of SA is observed in the tissues of diabetic mice which may be related to decreased synthesis of fibronectin, which contains SA in its core structure. Further, the decreased tissue SA levels are associated with oxidative stress-induced desialylation of glycoproteins [25]. Treatment with PTS has normalized SA levels in the plasma and tissues of diabetic mice, which could be due to the regulation of sialidase activity by insulin, since insulin is a more likely mediator of SA changes.

CONCLUSION

From the above observations, we concluded that the oral administration of PTS to diabetic mice reversed the changes in glycoprotein components in plasma, liver, and kidney. PTS may have a beneficial effect by the enhancement of insulin action in diabetic mice as evident by the decreased level of serum glucose in PTS-treated diabetic mice. Hence, the PTS may be useful in the preparation of drug ingredient for the prevention and control of diabetes mellitus.
