**ABSTRACT** Glioblastoma multiforme (GBM) is the most common primary intracranial tumor in adults and has poor prognosis. The GBM-specific tumor microenvironment (TME) plays a crucial role in tumor progression, immune escape, local invasion, and metastasis of GBM. Here, we demonstrate that hypoxia, reactive oxygen species (ROS), and differential concentration of glucose influence the expression of cytokines and chemokines, such as IL-6, IL-8, and IP-10, in human glial cell lines. Treatment with cobalt chloride (CoCl$_2$) and hydrogen peroxide (H$_2$O$_2$) significantly increased the expression levels of IL-6, IL-8, and IP-10 in a dose-dependent manner in CRT-MG and U251-MG astroglia cells, but not in microglia cells. However, we found strikingly different patterns of expression of cytokines and chemokines between H$_2$O$_2$-treated CRT-MG cells cultured in low- and high-glucose medium. These results suggest that astroglia and microglia cells exhibit distinct patterns of cytokine and chemokine expression in response to CoCl$_2$ and H$_2$O$_2$ treatment, and different concentrations of glucose influence this expression under either hypoxic or oxidant-enriched conditions.

**INTRODUCTION**

Glioblastoma multiforme (GBM) is the most common primary intracranial tumor in adults [1,2]. Because patients with GBM have a poor prognosis with a 5-year survival rate of 5% under optimal treatments, GBM is considered to be the most malignant glial tumor [3]. Common features of GBM include invasion into surrounding normal brain tissues, accelerated proliferation, the presence of necrosis, and high degree of infiltration of diverse immune cells, including microglia, microphages, and lymphocytes [4,5]. These remarkable features are believed to generate a GBM-specific tumor microenvironment (TME), which plays a crucial role in tumor progression, immune escape, local invasion, and metastasis of GBM [6-8].

The tumor and its surrounding microenvironment are closely related and interact constantly [9]. During the stages of tumor progression, a hypoxic TME or pro-oxidant-enriched TME is formed; these TMEs have both beneficial and harmful effects on tumor cells and their niche. The TME is characterized by low levels of glucose and amino acids, acidosis, and hypoxia [10,11]. A large tumor mass often produces a hypoxic TME, which is an important and common denominator of the complex metabolic changes and differentiation of cancer cells, leading to increased metastasis, invasion of cancer cells, and patient mortality [12]. A high degree of infiltration of diverse immune and inflammatory cells into tumor tissues contributes to the development of a pro-oxidant enriched TME. Reactive oxygen species (ROS) are known to mediate cancer cell invasion and metastasis by inducing Met...
overexpression, Matrix metalloproteinases (MMPs) secretion, and invadopodia formation [13]. Invasion of cancer cells into adjacent normal brain tissues and infiltration of immune cells into tumor tissues, which are important key features of GBM, are believed to be caused by interactions between the TME and cancer cells [4,5].

Chemokines are important mediators of the TME that regulate invasion and metastasis of cancer cells and infiltrated immune cells in diverse malignant tumors [14,15]. Chemokines are a large group of small chemotactic proteins that guide cell migration, control cells of the immune system, and promote angiogenesis. Chemokines are classified into 4 highly conserved groups (C, CC, CXC, and CX3C) based on the position of the first two cysteines adjacent to the amino terminus [16]. Among them, IL-8 acts as an important modulator of melanoma growth by enhancing cancer cell proliferation [17]. In GBM, IL-8 has been implicated in glioma angiogenesis and increased malignancy [18]. IP-10 (CXCL10) stimulation increases ERK1/2 activation, which contributes to the proliferation of GBM cells [19]. Induction of IL-6 is known to enhance proliferation and migration of GBM cells, by activating STAT3 [20].

In the present study, we investigated whether chemokine expression in GBM cells is affected by differential conditions of the TME, such as hypoxic and pro-oxidant-enriched micro-environments. Since the availability of glucose and acidity of the TME are known to modify the metabolic behavior of cancer cells, we also examined the effect of different concentrations of glucose on chemokine expression in either hypoxic or oxidant-enriched microenvironments.

**METHODS**

**Cells**

Human astroglialoma CRT-MG, U251-MG, and HMO6 human microglial cells were maintained in Dulbecco’s modified essential medium (DMEM, WelGENE Inc., Daegu, Korea) with 10% fetal bovine serum (Gibco, Grand Island, NY 14072, USA), 1% penicillin-streptomycin in a humidified 5% CO2 incubator at 37°C.

**Enzyme-linked immunosorbent assay (ELISA)**

Chemokines levels were measured in the culture supernatants of CRT-MG, U251-MG, and HMO6 in 60-mm culture plates at a final concentration of 9×10⁵ per well. After stabilization, cells were treated with either hydrogen peroxide (H₂O₂) or cobalt chloride (CoCl₂) for 24 h. For low and high glucose conditions, cells were cultured in low glucose DMEM (1,000 mg/L glucose), and high glucose DMEM (4,500 mg/L glucose), respectively. After treatment for 24 h, supernatants were collected, and IL-6, IL-8/CXCL8, and IP-10/CXCL10 concentrations were determined using a sandwich ELISA method with human IL-6 (BioLegend, San Diego, CA, USA), IL-8 (BioLegend), and IP-10 BD OptEIA™ (BD Biosciences, Franklin Lakes, NJ, USA) according to the manufacturer’s instructions. The concentration of chemokines in each sample was determined by referencing a standard curve generated using known amounts of IL-6, IL-8, and IP-10.

**RNA isolation and RT-PCR**

Total cellular RNA was isolated using RNA extract kit (EasyBlue™, Intron, Gyeonggido, Korea) according to the manufacturer’s protocol. cDNA was synthesized from 5 μg of total RNA with reverse transcription and PCR was performed using 1–9 μl cDNA with a thermal cycler (Bio-Rad Laboratories, Hercules, CA, USA). The primer sequences were as follows: GAPDH (glyceraldehyde-3-phosphate dehydrogenase), forward 5′-GGATACATCCATCATCTG-3′, reverse 5′-GTGATGGCATGGACTGTGG-3′; IL-6, forward 5′-ATGAACTCTTCTCTCCGGA-3′, reverse 5′-GTTTTCTGCCAGTGCCTCTTTG-3′; IL-8, forward 5′-CTCCAAACCTTTCCACCCC-3′, reverse 5′-GATTCTTGGATACACCACAGAATG-3′; IP-10, forward 5′-GTACCTCTCTCTAGAACCGTACG-3′, reverse 5′-GAGATCTGATTCTTGGATACACCACAGAATG-3′.

**Human phosphokinase array**

Cells were treated with or without H₂O₂ for 24 h in either high- or low-glucose medium, and then lysed with array lysis buffer. The protein concentration was quantified using the BCA method. Cell lysates were applied to the phosphoprotein array following the manufacturer’s instructions (Proteome Profiler™ Human Phosphokinase Array kit, R&D Systems). Blocking buffer was incubated with each membrane for 1 h on a rocking platform shaker. Cell lysates were diluted in array buffer and incubated overnight at 4°C. The array was incubated in each reconstituted detection antibody cocktail for 2 h at RT, and then was diluted streptavidin-HRP for 30 min, followed by application of chemiluminescent reagent. Chemiluminescent signals were quantified with the use of the luminescent image analyzer (LAS...
3000 imaging system; Fujifilm Corporation, Tokyo, Japan). The phosphokinase activity was measured by the changed spot intensity divided by reference spot intensity, using Image J software (version 1.6.0, U.S. National Institutes of Health).

Statistical analysis

The mean±standard deviation is shown in the bar graphs for the independent experiments, and statistical significance was analyzed by using ANOVA and the Student’s t-test with the SPSS software version 23.0 (SPSS Inc., Chicago, IL, USA). A value of p<0.05 was regarded as statistically significant.

RESULTS

Effect of CoCl₂ on the expression of chemokines in astrocytes and microglia

We initially examined the effect of CoCl₂, a mimic of hypoxia, on the expression of chemokines, such as IL-6, IL-8 (CXCL8), and IP-10 (CXCL10), in the CRT-MG and U251-MG astrogliaoma cell lines and HMO6 microglia cell line. Cells were either treated with CoCl₂ (0.1–1 mM) or not treated for 24 h, and then supernatants and cells were collected and analyzed via ELISA and RT-PCR, respectively. Treatment with CoCl₂ (0.5 and 1 mM) resulted in a significant increase in the expression levels of IL-6 and IL-8 in CRT-MG and U251-MG astrogliaoma cells (Figs. 1A, 1B, 1D, and 1E). The level of IP-10 in CRT-MG increased significantly with 0.5 and 1 mM CoCl₂ treatment (Fig. 1C). However, when treated with 1 mM of CoCl₂, the level of IP-10 was slightly reduced compared to that in the 0.5 mM CoCl₂-treated group. Increased IP-10 expression in U251-MG was found only in
the presence of 1 mM of CoCl₂ (Fig. 1F). To determine whether CoCl₂-induced chemokine expression is a common occurrence in different types of brain glial cells, we performed similar experiments with the HMO6 human microglial cell line. In the presence of 0.1–0.25 mM of CoCl₂, the levels of IL-6 and IL-8 in HMO6 increased, while 1 mM CoCl₂ treatment significantly reduced expression levels of IL-6 and IL-8 (Figs. 1G and 1H). In contrast to astroglial cells, the IP-10 expression level was decreased by CoCl₂ treatment in a dose-dependent manner in HMO6 (Fig. 1I). To examine the mRNA expression level of CRT-MG, U251-MG and HMO6 cells treated with or without 0.5 mM CoCl₂, RT-PCR for IL-6, IL-8 and IP-10 was performed. As shown in the inset to Figs. 1A-1H, CoCl₂ induced IL-6/IL-8 chemokine expression in all cell lines.

**Effect of H₂O₂ on the expression of chemokines in astrocytes and microglia**

To test whether H₂O₂ has an effect on chemokine expression in glial cells, CRT-MG and U251-MG human astroglioma cells and HMO6 human microglial cells were treated with H₂O₂ for 24 h. Subsequently, the levels of IL-6, IL-8, and IP-10 were examined via ELISA. H₂O₂ treatment induced a dose-dependent increase in the expression levels of IL-6, IL-8, and IP-10 up to a concentration of 0.5 mM in CRT-MG and U251-MG cells (Figs. 2A-2F). In microglia HMO6 cells, the expression levels of IL-6 and IL-8 increased in the presence of 0.1–0.25 mM of H₂O₂ compared with the control (Figs. 2G and 2H). There was a tendency toward a decrease with 0.5 mM of H₂O₂ compared with 0.1–0.25 mM of H₂O₂ (Figs. 2G, 2H, and 2I). To examine the mRNA expression level of CRT-MG, U251-MG and HMO6 cells treated with or without 0.5 mM H₂O₂, RT-PCR was performed. As shown in the inset to Figs. 2A, 2B and 2D, 2E, H₂O₂ significantly induced IL-6/IL-8 chemokine expression in astroglial cells, similar to data obtained from ELISA. These results indicate that the stimulation of astroglial cells by either H₂O₂ or CoCl₂ results in the increase of chemokine release in a dose-dependent manner, whereas high concentrations of H₂O₂ or CoCl₂ reduce chemokine expression in

**Fig. 2. Effect of H₂O₂ on IL-6, IL-8, and IP-10 expression.** CRT-MG, U251-MG, and HMO6 cells were either treated with the indicated concentrations of H₂O₂ or not treated for 24 h. After incubation, supernatants were collected, and the protein levels of chemokines from the culture supernatants were analyzed via ELISA for IL-6 (A, D, G), IL-8 (B, E, H), and IP-10 (C, F, I). Absorbance was measured at 450 nm. (Inset) RT-PCR of CRT-MG, U251-MG and HMO6 cells treated with or without 0.5 mM H₂O₂. Data shown are representative of at least three independent experiments. *p<0.05, **p<0.01, ***p<0.001 vs. untreated control.
HMO6 microglial cells.

Effect of low glucose on chemokine expression of CoCl$_2$-treated CRT-MG

High glucose is known to affect the expression pattern of chemokines and cytokines, leading to inflammation and leukocyte activation [21]. To test the effect of glucose concentration on CoCl$_2$-induced expression of proinflammatory chemokines, CRT-MG cells were treated with CoCl$_2$ for 24 h in either high or low glucose medium, and then the supernatants were analyzed via ELISA. In the presence of 0.5–1 mM of CoCl$_2$, the expression levels of IL-6, IL-8, and IP-10 were increased in both high and low glucose media (Fig. 3). IL-8 protein expression level showed a similar pattern of increase in both high and low glucose conditions (Figs. 3B and 3E). Interestingly, the amount of IL-6 and IP-10 protein detected from CRT-MG cultivated in low glucose medium was greater than that from cells cultivated in high glucose medium (Figs. 3D and 3F). These results indicate that low glucose augments further chemokine production in CoCl$_2$-treated CRT-MG compared to high glucose.

Effect of low glucose on chemokine expression of H$_2$O$_2$-treated CRT-MG

Next, to test whether the low glucose condition has an effect on proinflammatory chemokine expression in H$_2$O$_2$-treated cells, CRT-MG cells were treated with H$_2$O$_2$ at various concentrations (0–0.5 mM) for 24 h under either low or high glucose conditions, and then culture supernatants were analyzed via ELISA. In high glucose medium, treatment with H$_2$O$_2$ induced a dose-dependent increase in the expression levels of IL-6, IL-8, and IP-10 (Figs. 4A-4C), similar to the results shown in Figs. 2A-2C. As shown in Fig. 4D, low glucose levels abrogated the chemokine release of IL-6 in H$_2$O$_2$-treated CRT-MG. IL-8 production in cells grown in low glucose medium was increased in a dose-dependent manner, but to a lesser amount compared to that of cells in high glucose conditions (Fig. 4E). The level of IP-10 was induced by low glucose medium alone; however, treatment with H$_2$O$_2$ and low glucose decreased the expression level of IP-10. To examine the effect of low and high glucose on chemokine expression in response to H$_2$O$_2$ and CoCl$_2$ using co-cultured cells, we next performed indirect co-culture assays. CRT-MG and U251 astroglia cells were cultured in either low (1,000 mg/L) or high (4,500 mg/L) glucose medium with the indicated concentration of CoCl$_2$ for 24 h. After incubation, supernatants were collected and the level of IL-6 (A, D), IL-8 (B, E), and IP-10 (C, F) protein was measured via ELISA. Absorbance was measured at 450 nm. Data shown are representative of at least three experiments. *p<0.05, **p<0.01, ***p<0.001 vs. untreated control.
were placed on the 24 well-plate, and HMO6 microglia cells were seeded onto the microporous membranes of the transwell insert, and then cells were treated with either 0.5 mM H2O2 or 0.5 mM CoCl2 for 24 h under low and high glucose conditions. After incubation, total RNA from CRT-MG and HMO6 cells were extracted and analyzed by RT-PCR for IL-8. In co-culture condition, HMO6 microglia showed modest, but not significant, increase in mRNA expression of IL-8 by H2O2 and CoCl2 treatment, consistently in both low and high glucose conditions (Fig. 4G, right panel). In CRT-MG astroglioma cells co-cultured with microglia, we found that H2O2-induced IL-8 mRNA expression was significantly decreased by low glucose condition, while CoCl2-induced IL-8 mRNA expression was not affected (Fig. 4G, left panel), similar to results obtained from separate cultured cells (Figs. 3B, 3E, 4B and 4E). On using U251-MG and HMO6 co-cultured cells, we observed findings that were similar to the findings in CRT-MG and HMO6 co-culture as shown in Fig. 4G, showing decreased mRNA expression of IL-8 in H2O2-treated U251-MG cells by low glucose condition. We again observed that the mRNA expression level of IL-8 in HMO6 was not affected by 0.5 mM CoCl2 and H2O2 under either low or high glucose conditions (data not shown). These data suggest that the low glucose condition abrogates a stimulatory effect of H2O2 on the expression of protumorigenic chemokines in CRT-MG cells.

Glucose level influences the activation/phosphorylation of signaling molecules in CRT-MG

Since we found that the expression level of chemokines induced by H2O2 treatment was affected by glucose concentration, we next used a phosphokinase array to identify the signaling pathways that are involved in H2O2-induced chemokine expression under either high or low glucose conditions. CRT-MG cells cultured at low or high glucose levels were treated with 0.5 mM of H2O2 for 24 h, and then cell lysates were analyzed via a phosphokinase array. Compared to the array incubated with cell lysates obtained from control CRT-MG cells which were cultured in high glucose medium (Fig. 5A, upper left), the intensity of several spots changed in the arrays incubated with cell lysates from H2O2-treated, and/or low glucose-incubated CRT-MG cells. The protein phosphorylation, including GSK-3α/β, Fyn Y420, PRAS40 T246, P53 S392, and P53 S15, was higher in H2O2-treated CRT-MG cells cultivated in high glucose medium than in those cultured in low glucose medium (Fig. 5B, dashed box, a–e). The phosphorylation of P38α T180/Y182, MSK1/2 S376/S360, c-Jun S63, eNOS S1177, p27 T198, PLC-γ1 Y783, and PYK2 Y402 was increased both in H2O2-treated CRT-MG cells cultured in high glucose medium.
and in control CRT-MG in low glucose medium. However, this increased phosphorylation was not observed in H$_2$O$_2$-treated CRT-MG cells in the low glucose condition (Fig. 5B, solid box, A~G). These data indicate that low glucose level influences the activation/phosphorylation of various signaling molecules, as well as chemokine expression, in H$_2$O$_2$-treated CRT-MG cells.

**DISCUSSION**

In this study, we demonstrate that hypoxia, ROS, and differential concentration of glucose influence the expression of cytokines and chemokines, such as IL-6, IL-8, and IP-10, in human glial cell lines. Treatment with CoCl$_2$ and H$_2$O$_2$ significantly increased the expression levels of IL-6, IL-8, and IP-10 in a dose-dependent manner in CRT-MG and U251-MG astrogliaoma cells, but not in HMO6 microglia cells. Interestingly, low glucose level abrogated the stimulatory effect of H$_2$O$_2$ on the expression of IL-6 and IP-10 in CRT-MG cells. Our results provide evidence that astrogliaoma and microglia cells exhibit distinct patterns of cytokine and chemokine expression in response to CoCl$_2$ and H$_2$O$_2$ treatment and that different concentrations of glucose differentially regulate the expression level of these chemokines under either hypoxic or oxidant-enriched conditions.

Treatment with CoCl$_2$ and H$_2$O$_2$ significantly increased the level of chemokine expression in a dose-dependent manner in CRT-MG and U251-MG astrogliaoma cells. When HMO6 cells were incubated under the same conditions, we found that the levels of IL-6 and IL-8 were increased at low concentrations (0.1~0.25 mM) of CoCl$_2$ and H$_2$O$_2$, but decreased at high concentrations (>0.5 mM) of CoCl$_2$ and H$_2$O$_2$. Furthermore, IP-10 production in HMO6 was decreased in response to CoCl$_2$ and H$_2$O$_2$ in a dose-dependent manner. To assess the cytotoxicity of CoCl$_2$ and H$_2$O$_2$ using the CCK-8 assay, we found the viability of...
and hypoxia [26]. In our system, treatment with CoCl₂ acts as a modulator of melanoma growth by enhancing cancer cell malignancy in GBM [18]. In addition, IL-8 acts as an important chemokine in glioma angiogenesis and increased growth [27]. Overexpression of CXCL3 and CXCL10 in GBM plays an important role in tumor growth and progression [28]. The CXCL12-CXCR4/R7 system plays a central role in tumor development and tumor cell proliferation via an autocrine/paracrine mechanism and contributes to the dissemination and invasiveness of several human cancers, including pancreatic, colon, ovarian, prostate, breast, renal carcinomas, lymphoma, melanoma, neuroblastoma, and GBM [29]. In this paper, we have examined the expression of these three chemokines, but it is necessary to confirm the effect of hypoxia, ROS, and differential concentration of glucose on the expression of other chemokines in the future.

High glucose is known to affect the expression pattern of chemokines and cytokines, leading to inflammation and leukocyte activation [21]. Moreover, an abundance of glucose is known to modify the metabolic behavior of cancer cells [30]. These results suggest that glucose concentration may have different effects on various TMEs, such as a hypoxic or pro-oxidant-enriched microenvironment. In this study, we examined the effect of different concentrations of glucose on chemokine and cytokine expression under either hypoxic or oxidant-enriched conditions, and found that different concentrations of glucose influenced the expression patterns of IL-6, IL-8, and IP-10 following CoCl₂ and H₂O₂ exposure. As shown in Fig. 5, low glucose condition influenced and reduced the activation/phosphorylation of various signaling molecules as well as chemokine expression in H₂O₂-treated CRT-MG cells. Under the oxidant-enriched condition, no effect of low glucose on induction of chemokine expression was observed, whereas the CoCl₂-induced hypoxic condition and low concentration of glucose showed synergistic effects on chemokine expression, at least for IL-6, IL-8, and IP-10 in CRT-MG cells (Figs. 3 and 4). Collectively, these data suggest that low glucose level may abrogate the stimulatory effect of H₂O₂ on the expression of protumorigenic cytokines and chemokines in glioblastoma cells. The data also suggest that low glucose conditions may have different consequences when combined with other conditions in GBM.

Here, we examined the effect of CoCl₂, a mimetic of hypoxia, and H₂O₂ on the expression of chemokines such as IL-6, IL-8, and IP-10 in CRT-MG and U251-MG astroglia cells lines and HMO6 microglia cell line. We show that astroglia cells and microglia exhibit distinct patterns of cytokine and chemokine expression in response to CoCl₂ and H₂O₂ treatment, and different concentrations of glucose influence IL-6, IL-8, and IP-10 expression under either hypoxic or oxidant-enriched conditions. Interestingly, our results demonstrate that low glucose condition abrogated the stimulatory effect of H₂O₂ on the chemokine expression in astroglia cells, but not in HMO6 microglia cells. These results suggest that microglia consistently secrete...
these chemokines in response to varied conditions of tumor microenvironment, compared to GBM cells; however, astroglioma cells could act as major players in GBM tumor microenvironment through producing more chemokines than microglia in response to some stimuli.
