Abstract

The constrained linear quadratic regulation problem is solved by a continuous piecewise affine function on a set of state space polytopes. It is an obvious question whether this solution can be built up iteratively by increasing the horizon, i.e., by extending the classical backward dynamic programming solution for the unconstrained case to the constrained case. Unfortunately, however, the piecewise affine solution for horizon \( N \) is in general not contained in the piecewise affine law for horizon \( N + 1 \). We show that a backward dynamic programming does, in contrast, result in a useful structure for the set of the active sets that defines the solution. Essentially, every active set for the problem with horizon \( N + 1 \) results from extending an active set for horizon \( N \), if the constraints are ordered stage by stage. Consequently, the set for horizon \( N + 1 \) can be found by only considering the constraints of the additional stage. Furthermore, it is easy to detect which polytopes and affine pieces are invariant to increasing the horizon, and therefore persist in the limit \( N \to \infty \). Several other aspects of the structure of the set of active sets become evident if the active sets are represented by bit tuples. There exists, for example, a subset of special active sets that generates a positive invariant and persistent (i.e., horizon invariant) set around the origin. It is very simple to identify these special active sets, and the positive invariant and persistent region can be found without solving optimal control or auxiliary optimization problems. The paper briefly discusses the use of these results in model predictive control. Some opportunities for uses in computational methods are also briefly summarized.

1 Problem statement and introduction

We consider the constrained linear quadratic optimal control problem with finite and infinite horizons. The problem for finite horizon \( N \) reads

\[
V^*(x(0), [0, N]) := \min_{x(k), k=0,\ldots,N-1; u(k), k=0,\ldots,N-1} \left( \frac{1}{2} \|x(N)\|_P^2 + \frac{1}{2} \sum_{k=0}^{N-1} (\|x(k)\|_Q^2 + \|u(k)\|_R^2) \right)
\]

subject to

\[
x(k+1) = Ax(k) + Bu(k), \quad k = 0,\ldots,N-1 \quad \text{(1b)}
\]

\[
u(k) \in U, \quad k = 0,\ldots,N-1 \quad \text{(1c)}
\]

\[
x(k) \in X, \quad k = 0,\ldots,N-1 \quad \text{(1d)}
\]

\[
x(N) \in T, \quad \text{(1e)}
\]

where \( x(0) \) is the given initial condition, \( x(k) \in \mathbb{R}^n \) and \( u(k) \in \mathbb{R}^m \) are the state and input variables, respectively, and the matrices have the obvious dimensions. We assume \((A, B)\) to be controllable, \( Q \succeq 0, \quad R \succ 0 \) and \( X, U \) to be compact convex polytopes that contain the origin in their interiors. Furthermore, \( P \)
is assumed to be the solution to the discrete-time algebraic Riccati equation, and \( T \subset \mathbb{R}^n \) is assumed to be the largest set such that the solution to (1) and the solution to the unconstrained infinite-horizon problem are equal for all \( x(0) \in T \).

The infinite-horizon problem results in the limit \( N \to \infty \) if the first term in (1a) and (1e) are omitted. The unconstrained infinite-horizon problem results if (1c) and (1d) are also omitted.

We briefly recall that \( u = K_\infty x \) with

\[
K_\infty = -(B^T PB + R)^{-1} B^T PA
\]

is the state feedback that solves the unconstrained infinite-horizon problem, (see, e.g., [4, chapter 4]). Furthermore, we recall that

\[
T = \{ \xi \in \mathcal{X} | (A + BK_\infty)^k \xi \in \mathcal{X}_U, k \geq 0 \}
\]

where \( \mathcal{X}_U = \{ \xi \in \mathcal{X} | K_\infty \xi \in U \} \). Some properties of \( T \) are summarized in the notation section.

Let \( u^*(0), u^*(1), \ldots, u^*(N-1) \) for (1) has a solution, where \( \mathcal{F}_N \neq \emptyset \) since \( \mathcal{F}_N \supseteq \cdots \supseteq \mathcal{F}_1 \supseteq T \neq \emptyset \).

The paper addresses the following problem: It is known that \( u^*_N : \mathcal{F}_N \to \mathbb{R}^{mN} \) is a continuous piecewise affine function on a partition of \( \mathcal{F}_N \) into a finite number of polytopes \( \mathcal{P}_{N,1}, \mathcal{P}_{N,2}, \ldots \) (see also [12]). It is an obvious question whether this piecewise structure can be built up iteratively (i.e., starting from \( u^*_0 : \mathcal{F}_0 \to \mathbb{R}^{mN} \) with \( \mathcal{F}_0 = T \) and finding \( \mathcal{F}_1, \mathcal{F}_2, \ldots \)) or recursively (i.e., starting from some \( \mathcal{F}_N \) and investigating \( \mathcal{F}_{N-1}, \mathcal{F}_{N-2}, \ldots \)). Unfortunately, the piecewise affine and polytopic geometry of \( u^*_N \) and \( u^*_{N+1} \) are not related in any obvious way. For example, a polytope for horizon \( N \) may or may not be a polytope for horizon \( N + 1 \) (see Figure 1). It is the purpose of the paper to explain that the sought-after structure does indeed exist for the active sets of (1), and to relate this algebraic structure of the set of active sets to the geometric structure of polytopes and the affine functions defined on them.

Dynamic programming and the principle of optimality, which are instrumental in Section 3, are fundamental techniques and have been standard tools for the derivation of the solution to the unconstrained infinite-horizon problem for decades (see, e.g., [1]). Their application to the constrained problem is hampered by the piecewise quadratic structure of the optimal cost function. Several publications have addressed this problem with a focus on model predictive control (MPC). Muñoz de la Peña et al. [6] present an algorithm for the explicit construction of the piecewise affine MPC law by backward dynamic programming based on techniques proposed in [13, 15]. Bakarč et al. [2] show how to approximate the piecewise optimal cost function by a single quadratic function, which results in a considerable simplification of backward dynamic programming for the constrained case. The inherent complexity of the problem is also evident from the number of candidate active sets (the powerset of \{1, \ldots, q\} if \( q \) constraints exist) that need to be analyzed to find the active sets that actually define the optimal solution. Gupta et al. [9] show that many candidate active sets can be
disregarded if the powerset is organized as a tree and subtrees are pruned whenever they stem from a candidate set that is not an active set (see also [7,11]).

The results presented here are also based on an analysis of the set of active sets, but we focus on the structure of the solution of the optimal control problem (1), specifically relaxing requirements for stability). The properties summarized so far are then exploited in Section 2.2 (see the remark at the end of Section 2.1). Section 3 briefly summarizes some computational aspects. Some conclusions and opportunities for future work are stated in Section 4.

Notation and preliminaries

Problem (1) is finite-dimensional and thus solved by a finite input sequence \( \bar{u} \) and a corresponding finite state sequence that results in (1). More generally, \( u^*(l), \ldots, u^*(N-1) \) is optimal for (1) with horizon \( N-l \) and initial condition \( x^*(l) \), where \( l \in \{0, N - 1\} \) is arbitrary. (ii) In general, \( \bar{u} \) is not equal to the first elements in the optimal input sequence for (1) with horizon \( N+1 \) and initial condition \( x^*(1) \).

The terminal set \( T \) introduced in (1) can be computed with the procedure proposed in [8]. It does not depend on \( N \) and \( T \subseteq X \) by definition [5]. Moreover, \( x^*(N) \in \text{int}T \) implies (4) are equal for \( N \) and \( N+1 \). and thus for all \( N+l, l \geq 0 \) and in the limit \( N \to \infty \) (see Lemma 2.2 in [5] 3).

For any \( N \), there exist \( H, Y, E, G, E, w \) such that problem (1) can equivalently be stated as the quadratic program

\[
\begin{align*}
\min & \quad \frac{1}{2} x^T(0)Yx(0) + \frac{1}{2} u^T H u + x(0)^T F u \\
\text{subject to} & \quad Gu \leq w + Ex(0)
\end{align*}
\]

after substituting (1b), where \( u = (u^T(0), \ldots, u^T(N - 1))^\top \), and where the state sequence that results in (1) can be determined with (1b). \( H \) is positive definite under the assumptions stated for (1) [3]. Consequently, (1) has a unique solution for all \( x(0) \in F_N \), which we denote \( w_N(x(0)) \) in accordance with \( w_N : F_N \to \mathbb{R}^{mN} \) introduced above. Let \( q \) refer to the number of inequality constraints in (1) and (6). Let \( q_\mathcal{U}, q_\mathcal{X} \) and \( q_T \) refer to the number of halfspaces (i.e., inequalities) required to define \( \mathcal{U}, \mathcal{X} \) and \( \mathcal{T} \), respectively. Polytopes are understood to be the intersection of a finite number of halfspaces and bounded.

A constraint \( i \) is called active (resp. inactive) for an \( x(0) \in F_N \) if \( G_i w_N(x(0)) = w_i + E_i x(0) \) (resp. \( G_i w_N(x(0)) < w_i + E_i x(0) \)), where \( G_i, w_i, E_i \) etc. refer to the \( i \)-th row of the respective matrix or vector. \( G_\mathcal{A}, G_\mathcal{T} \) etc. refer to the submatrix of \( G \) with rows indicated in \( \mathcal{A} \) and \( \mathcal{T} \), respectively. For a given \( x(0) \in F_N \), let \( \mathcal{A} \) and \( \mathcal{T} \) (or \( \mathcal{A}(x(0)) \) and \( \mathcal{T}(x(0)) \)) where needed) refer to the set of active respectively inactive constraints. We say \( \mathcal{A} (\mathcal{T}) \) is an active (inactive) set for (1) if there exists an \( x(0) \in F_N \) with this set of active (inactive) constraints.

If \( \mathcal{A} \) is an active set for (6), the first order optimality conditions can be stated in the form

\[
\begin{align*}
Hu + G_\mathcal{T} \sigma + F_\mathcal{T} x(0) &= 0 \\
G_\mathcal{A} u - w_\mathcal{A} - E_\mathcal{A} x(0) &= 0 \\
G_\mathcal{T} u - w_\mathcal{T} - E_\mathcal{T} x(0) &\leq 0 \\
\sigma_\mathcal{T} &= 0, \quad \sigma_\mathcal{A} \geq 0
\end{align*}
\]

with multipliers \( \sigma \in \mathbb{R}^q \). They are solved by one of the affine functions that constitute the piecewise

\[1\text{The condition } x(N) \in \text{int} T \text{ cannot be replaced by } x(N) \in T \text{ as in [3]. See Example 7.}\]
affine $u_N^*: \mathcal{F}_N \to \mathbb{R}^{mN}$ for one of the polytopes $\mathcal{P}_{N,i}$ \[3\]. It is therefore meaningful to say $\mathcal{A}$ defines a polytope $\mathcal{P}$ and the optimal $u_N^*(x(0))$ for all $x(0) \in \mathcal{P}$ and to refer to this polytope by $\mathcal{P}(\mathcal{A})$. More precisely, $\mathcal{P}(\mathcal{A})$ is defined as the relative interior of the set of initial states such that \[7\] has a solution for the active set $\mathcal{A}$, which implies $\mathcal{P}(\mathcal{A})$ is relative open. Because the solution to \[1\] is continuous, the affine law $x(0) \to u_N^*(x(0))$ can be extended from int $\mathcal{P}(\mathcal{A})$ to the boundary of $\mathcal{P}(\mathcal{A})$. Cumbersome statements about boundaries can be avoided with these definitions. For example, the interior of the central polytope in Figure \[4\] and the optimal solution on its closure are defined by a single $\mathcal{A}$, while eight different active sets (for 4 vertices and 4 facets), which all define the same optimal solution as $\mathcal{A}$, exist on its boundary. By using the notions "relative interior" and "relative openness" the statements in the paper become more precise. For example, the interior of the central polytope is denoted and its relative interior is their interior, we use the notation "int $\mathcal{X}$" etc. to refer to their interiors explicitly, while all other polytopes are understood to be open.

Active sets of constraints are stated as tuples of bits. This proves to be convenient when considering the constraints stage by stage in \[1\] and the infinite-horizon problem. For example, a tuple of $q$ bits $\alpha = (\alpha_1, \ldots, \alpha_q)$ uniquely represents a set of active constraints $\mathcal{A} \subseteq \{1, \ldots, q\}$, where

$$
\alpha_i = \begin{cases} 
1 & \text{if } i \in \mathcal{A} \\
0 & \text{otherwise} 
\end{cases} \quad (8)
$$

The concatenation of two or more tuples, say, $\alpha = (\alpha_1, \ldots, \alpha_q)$ and $\alpha' = (\alpha'_1, \ldots, \alpha'_p)$ is denoted as $\alpha \alpha' = (\alpha_1, \ldots, \alpha_q, \alpha'_1, \ldots, \alpha'_p)$. We use $\alpha$ and $\mathcal{A}$, $G_\alpha$ and $G_\mathcal{A}$, $\mathcal{P}(\mathcal{A})$ and $\mathcal{P}(\alpha)$ etc. interchangeably.

2 The structure of the set of active sets

2.1 Stagewise active set construction

We illustrated with Figure \[1\] that the optimal feedback law and its polytopes for \[1\] with horizon $N$ are not contained in the law and polytopes for $N + 1$. Such a property does hold for the active sets, however. This is stated more precisely in Proposition \[1\]. As a preparation, the order of the constraints has to be agreed on. We stress that we can fix the order of the constraints without restriction, since the optimal solutions to \[1\] and \[6\] are invariant to changing this order. Apart from the order stated in \[1c\]–\[1e\], it is natural to order the constraints stage by stage, i.e.,

$$
x(0) \in \mathcal{X}, u(0) \in \mathcal{U}
$$

$$
x(1) \in \mathcal{X}, u(1) \in \mathcal{U}
$$

$$
\vdots
$$

$$
x(N-1) \in \mathcal{X}, u(N-1) \in \mathcal{U}
$$

$$
x(N) \in \mathcal{T}
$$

where all but the last line correspond to $q_{x} + q_{\mu}$ halfspace constraints, and the last line corresponds to $q_{T}$ such constraints.

Proposition 1. Consider the optimal control problem \[1\] for horizons $N$ and $N + 1$. Assume without restriction the constraints are ordered as in \[4\]. Then for every active set $\alpha_{N+1}$ of the problem with horizon $N + 1$ there exists an active set $\alpha_{N}$ for the problem with horizon $N$ such that

$$
\alpha_{N+1} = \alpha \alpha_{N} \quad (10)
$$

for some $\alpha$ of length $q_{x} + q_{\mu}$.

Proof. We introduce the abbreviations $\ell_{T}(\xi) = \frac{1}{2}||\xi||_{Q}^2$, $\ell(\xi, \mu) = \frac{1}{2}(||\xi||_{Q}^2 + ||\mu||_{L}^2)$ and generalize \[1\] to $V^*(\xi, [N_1, N_2]) :=$

$$
\min_{x(N_1 + 1), \ldots, x(N_2), u(N_1), \ldots, u(N_2-1)} \sum_{k=N_1}^{N_2-1} \ell(x(k), u(k))
$$

(11a)

---

\[2\]Proposition \[1\] for example, applies to active sets that define lower than $n$-dimensional polytopes.
subject to
\[ x(N_1) = \xi \]  
(11b)
\[ x(k + 1) = Ax(k) + Bu(k), \quad k = N_1, \ldots, N_2 - 1 \]  
(11c)
\[ u(k) \in \mathcal{U}, \quad k = N_1, \ldots, N_2 - 1 \]  
(11d)
\[ x(k) \in \mathcal{X}, \quad k = N_1, \ldots, N_2 - 1 \]  
(11e)
\[ x(N_2) \in \mathcal{T} \]  
(11f)
for \( N_2 > N_1 \). Since \( A, B, P, Q, R, \mathcal{U}, \mathcal{X} \) and \( \mathcal{T} \) are time-invariant, \( V^*(\xi, [N_1, N_2]) \) only depends on \( N_2 - N_1 \), i.e.,
\[ V^*(\xi, [N_1, N_2]) = V^*(\xi, [t, N_2 - N_1 + t]) \quad (12) \]
for all \( t \in \mathbb{N} \cup \{0\} \) and all \( \xi \in \mathcal{F}_{N_2-N_1} \). Now consider the case \( N_1 = 0, \quad N_2 = N + 1 \), i.e., \( V^*(\xi, [0, N + 1]) \). Expressing \( V^*(\xi, [0, N + 1]) \) in terms of \( V^*(\xi, [1, N + 1]) \) in a fashion similar to backward dynamic programming yields \( V^*(\xi, [0, N + 1]) = \)
\[ \min_{\xi, u(0), w} \left( \ell(x(0), u(0)) + V^*(\xi, [1, N + 1]) \right) \quad (13a) \]
subject to
\[ x(1) = Ax(0) + Bu(0), \quad x(0) = \xi, \quad \xi = x(1) \]  
(13b)
\[ x(0) \in \mathcal{X}, u(0) \in \mathcal{U} \]
Since \( V^*(\xi, [1, N + 1]) = V^*(\xi, [0, N]) \) according to (12), and with the notation (6) for \( V^*(\xi, [0, N + 1]) \),
(13a) can be replaced by
\[ \min_{\xi, u(0)} \left( \ell(x(0), u(0)) + \min_{w} \left( \frac{1}{2} \xi^T \mathbf{Y} \xi + \frac{1}{2} u(0)^T H u(0) \right) \right) \]  
(14)
where \( w = (u(1), \ldots, u(N))^T \) here. Just as there exist matrices \( H, Y \) etc. that transform \( V^*(\xi, [0, N + 1]) \) into (6), there exist \( Y, H, G, E \) and \( w \) such that
\[ \ell(x(0), u(0)) = \frac{1}{2} \xi^T Y \xi + \frac{1}{2} u(0)^T H u(0) \quad (15) \]
and (13b) can be stated as
\[ Gu(0) \leq w + E \xi \]  
(16)
\[ \xi = A \xi + Bu(0) \]
where (13b) has \( g_x + g_u \) constraints if \( g_x \) and \( g_u \) halfspaces define \( \mathcal{X} \) and \( \mathcal{U} \), respectively. Combining (13)–(16) yields \( V^*(\xi, [0, N + 1]) = \)
\[ \min_{\xi, u(0), \tau} \left( \frac{1}{2} \xi^T \mathbf{Y} \xi + \frac{1}{2} u(0)^T H u(0) \right) \]
\[ + \frac{1}{2} \xi^T \mathbf{Y} \xi + \frac{1}{2} u(0)^T H u(0) + \zeta^T F u \]  
(17a)
subject to
\[ Gu(0) \leq w + E \xi \]  
(17b)
\[ \xi = A \xi + Bu(0) \]
\[ \zeta = A \xi + Bu(0) \]
\[ Gu(0) \leq w + E \xi \]
where the minimization with respect to \( u \) can be applied to all terms of the cost function without restriction. The first order optimality conditions for (17) read
\[ \mathbf{Y} \zeta + \mathbf{F} u - \mathbf{E}^T \sigma + \tau = 0 \]  
(18a)
\[ H u(0) + G^T \lambda - B^T \tau = 0 \]  
(18b)
\[ H u + \mathbf{F}^T \zeta + \mathbf{G}^T \sigma = 0 \]  
(18c)
\[ Gu(0) - w - E \xi \leq 0 \]  
(18d)
\[ Gu - w - E \zeta \leq 0 \]  
(18e)
\[ \zeta = A \xi + Bu(0) \]  
(18f)
\[ \lambda_i (Gu(0) - w - E \xi)_i = 0 \quad \text{for all} \quad i \]  
(18g)
\[ \sigma_j (Gu - w - E \zeta)_j = 0 \quad \text{for all} \quad j \]  
(18h)
\[ \lambda \geq 0 \]  
(18i)
\[ \sigma \geq 0. \]  
(18j)
Since the constraints are ordered as in (9), (18d) and (18e) must be understood to be ordered as
\[ \begin{pmatrix} G & \mathbf{G} \\ \mathbf{G} & \mathbf{G} \end{pmatrix} \begin{pmatrix} u(0) \\ \zeta \end{pmatrix} \leq \begin{pmatrix} E & \mathbf{E} \\ \mathbf{E} & \mathbf{E} \end{pmatrix} \begin{pmatrix} \xi \\ \zeta \end{pmatrix} + \begin{pmatrix} w \\ w \end{pmatrix} \]
(19)
Now let \( \alpha_{N+1} \) be an arbitrary active set for (17) and let \( \xi \in \mathcal{F}_{N+1} \) be an arbitrary initial condition such
that \( \alpha_{N+1} \) is the active set. We partition \( \alpha_{N+1} \) according to

\[
\alpha_{N+1} = \alpha^- \alpha^+.
\]

(20)

where \( \alpha^- \) corresponds to the \( q_N + q_d \) rows of \( G, E \) and \( \alpha^+ \) to the remaining rows. Let \( \tilde{\alpha}^- \) and \( \tilde{\alpha}^+ \) be the corresponding inactive sets. Using these active and inactive sets, the optimality conditions (18) can equivalently be stated with separated active and inactive constraints (see (7)). More precisely, there exist \( \sigma^*, \tau^* \) and \( \lambda^* \) such that (18) holds for \( \xi, u(0)^*, \zeta^*, \mu^*, \sigma^*, \tau^* \) and \( \lambda^* \) if and only if

\[
\begin{align*}
Y \zeta + F u^* - E^T \sigma^* + \tau^* &= 0 \\
H u(0)^* + G_{\alpha^-}^T \lambda_{\alpha^-} - B^T \tau^* &= 0 \\
\lambda_{\alpha^-} &= 0 \\
(G u^* - w - E \xi)_{\alpha^-} &= 0 \\
(G u^* - w - E \xi)_{\alpha^+} &\leq 0 \\
\zeta^* &= A \xi + B u(0)^* \\
\lambda^* &= 0 \\
\sigma^* &\geq 0.
\end{align*}
\]

(21)

Since (21c), (21e), (21g) are the optimality conditions of (6), i.e., of \( V^*(\zeta, [0, N]) \), we have \( \zeta = x(1) \in F_N \) and \( \tilde{\alpha}^- \) is an active set of \( V^*(\zeta, [0, N]) \).

Since \( \alpha_{N+1} \) was an arbitrary active set of \( (17) \) and since \( \alpha \) can be partitioned as in (20), claim (10) holds with \( \alpha = \alpha^- \), \( \tilde{\alpha} = \alpha^+ \).

A shorter proof of Proposition 1 can be stated based on (11), (12) and by referring to the principle of optimality in dynamic programming (see, e.g., [4, chapter 1.3]). In particular, the optimality conditions (7) and (18) would not be required in this case. We state the more detailed proof, because it shows that constraint qualifications and weakly active constraints play no role for Proposition 1 while they often result in special cases elsewhere (see, e.g., [9, section 3.4.1], [17, section 5], [3, section 4.1.1]). A case where the linear independence constraint qualification fails but Proposition 1 still applies is given in Example 3 part (ii).

It is easy to see that truncating an active set by removing stages ”on the left” as in (10) results in active sets that define the optimal solution to (1) on a shrinking horizon:

**Corollary 2.** Consider (1) for horizon \( N \) and assume the constraints to be ordered as in (9) without restriction. Let \( \alpha_N \) be an arbitrary active set and partition \( \alpha_N \) according to

\[
\begin{align*}
\alpha_N &= \alpha_{N,0} \cdots \alpha_{N,N-1} \alpha_{N,N} \\
&= \underbrace{\alpha_{N,0} \cdots \alpha_{N,1}}_{q_N + q_d} \underbrace{\alpha_{N,0} \cdots \alpha_{N,1}}_{q_N + q_d} \underbrace{0}_q
\end{align*}
\]

Let \( x(0) \) be an arbitrary initial condition that results in the active set \( \alpha_N \) and let \( x^*(k), k \geq 0 \) introduced in (4) refer to the optimal solution for \( x(0) \). Then, for all \( l \in \{0, \ldots, N-1\} \), the active set

\[
\alpha_{N-l} = \alpha_{N,l} \cdots \alpha_{N,N}
\]

defines the optimal solution for (1) with horizon \( N-l \) and initial condition \( x^*(l) \).

**Proof.** It suffices to prove the claim for \( l = 1 \) and to apply this case repeatedly. We showed in the proof of Proposition 1 that \( \alpha_N \) is the active set for the optimal successor state \( \zeta = x^*(1) \) and (1) with horizon \( N \), if \( \alpha_{N+1} \) is the active set for \( x(0) \) and horizon \( N+1 \). With the substitutions \( N+1 \rightarrow N \) and \( N \rightarrow N-1 \), the claim for \( l = 1 \) results.

**Corollary 2** essentially extends remark (i) made in the notation section from the optimal sequences of states and states (4) to active sets. The corresponding extension to polytopes appears in part (i) of Remark 1.

Proposition 1 and Corollary 2 are illustrated with Example 3. All active sets and their properties stated in Example 3 can be checked with simple calculations, which are not stated here.

**Example 3.** Consider (1) for

\[
A = \begin{bmatrix}
-\frac{1}{2} & \frac{1}{2} \\
-\frac{1}{2} & -\frac{1}{2}
\end{bmatrix}, \quad B = \begin{bmatrix} 1 \\
1 \end{bmatrix},
\]

\[\mathcal{X} = \{ x \in \mathbb{R}^2; -10 \leq x_i \leq 10, i = 1, 2 \}, \quad \mathcal{U} = \{ u \in \mathbb{R}; -1 \leq u \leq 1 \}, \quad Q \text{ is the identity matrix, } R = 0.1\]
and $P$ and $T$ are as in Section 1. Note that $q_X + q_U = 6$, and $q_T = 4$ results for this example. Figure 2 shows the polytopes for $N = 1$ and $N = 2$, which illustrate the following cases of Proposition 1:

(i) Active sets for horizon $N$ may be extended to exactly one, more than one, or no active set at all. For example, the following active set for $N = 1$ is extended to exactly one active set for $N = 2$:

\[
\begin{align*}
000000.0001 & \quad (N = 1) \\
100000.000000.0001 & \quad (N = 2)
\end{align*}
\]

(green polytopes in Figure 2; dots are introduced every $q_X + q_U = 6$ positions for convenience). The following active set for $N = 1$ is extended to three active sets for $N = 2$:

\[
\begin{align*}
100000.0000 & \quad (N = 1) \\
000000.100000.0000 & \quad (N = 2) \\
100000.100000.0000 & \quad (N = 2) \\
010000.100000.0000 & \quad (N = 2)
\end{align*}
\]  

(yellow polytopes). The active set

\[
100000.000000.0001 \quad (N = 2)
\]

is not extended to any set for $N = 3$ (one of the yellow polytopes for $N = 2$ in Figure 2; $N = 3$ not shown).

(ii) Active sets that respect the linear independence constraint qualification (licq) for $N + 1$ may result from extending an active set that does not (or vice versa). For example, the following active sets appear in the example

\[
\begin{align*}
010000.0001 & \quad (N = 1) \\
000000.010000.0001 & \quad (N = 2)
\end{align*}
\]

and simple calculations show that the latter does and the former does not respect licq (blue polytopes).

Proposition 1 and Corollary 2 do not require the assumptions on $P$, $K_\infty$ and $T$ stated in Section 1 to hold and therefore apply to a larger problem class. All statements in Section 2.2, in contrast, do require the assumptions on $P$, $K_\infty$ and $T$ stated in Section 1 to hold. Example 3 respects the assumptions on $P$, $K_\infty$ and $T$ just so the same example can be used throughout the paper.
2.2 Persistency of active sets, polytopes and optimal solutions

Whenever a polytope and the optimal solution on it are defined by an active set for which all terminal constraints are inactive, this polytope and the optimal solution do not change when the horizon is extended. The following lemma and proposition state this more precisely.

**Lemma 4.** Consider the optimal control problem and assume without restriction the forward constraint order is used. Let be an arbitrary index set with length and let . The index set

\[
\hat{\alpha} \, 0 \ldots 0 \quad \text{ (23)}
\]

is an active set for horizon if and only if the active set

\[
\hat{\alpha} \, 0 \ldots 0 \ldots 0 \ldots 0 \quad \text{ (24)}
\]

is an active set for horizon .

**Proof.** It suffices to prove the claim for , since the cases follow by induction. To show an active set implies the existence of , let be an arbitrary initial condition that results in (23). Since implies inactivity of the terminal constraints, we have

\[
x^*(N) \in \text{int } \mathcal{T}. \quad \text{ (25)}
\]

Consequently, [5] applies and the infinite-horizon problem and the finite-horizon problem for horizons , have the same optimal solution, which we denote

\[
u^*(k), x^*(k), k \geq 0. \quad \text{ (26)}
\]

It remains to prove the active set for and horizon has the form for this solution, which can be done by showing for all and . It is easy to show that implies

\[
x^*(N+l) \in \text{int } \mathcal{T} \quad \text{ (27)}
\]

due to the positive invariance of (see Lemma in the appendix). This in particular implies

\[
x^*(N+1) \in \text{int } \mathcal{T}. \quad \text{ (28)}
\]

Since , and since follows from , we also have

\[
x^*(N) \in \mathcal{X}. \quad \text{ (29)}
\]

The proof for is somewhat technical. It is easy to show that there exists a such that \(x^*(N) \in \lambda \mathcal{T} := \{\lambda \xi | \xi \in \mathcal{T}\} \) and \(\lambda \mathcal{T} \subset \mathcal{T}\), because \(x^*(N) \in \text{int } \mathcal{T}, \lambda \xi \in \mathcal{T} \) for all \(\lambda \) and \(\mathcal{T}\) is convex. Now \(x^*(N) \in \lambda \mathcal{T}\) implies there exists a such that \(x^*(N) = \lambda \xi\). By definition of \(\mathcal{T}\), \(\xi \in \mathcal{K}_u\) and by definition of \(\mathcal{K}_u\) we have \(K_\infty \xi \in \mathcal{U}\). From

\[
\frac{1}{\lambda} \nu_\infty x = K_\infty \frac{1}{\lambda} \nu_\infty = K_\infty \xi \in \mathcal{U}
\]

we infer \(K_\infty x^*(N) \in \mathcal{U}\). Together with \(0 \in \mathcal{U}\) and the convexity of \(\mathcal{U}\) this implies \(K_\infty x^*(N) \in \mathcal{U}\). Therefore

\[
u^*(N) = K_\infty x^*(N) \in \mathcal{U}. \quad \text{(30)}
\]

To show an active set implies the existence of , let , let be an arbitrary initial condition that results in (24), and let denote the optimal solution for horizon , which now needs to be shown to be optimal for . The trailing zeros in (24) imply the constraints in stages and are inactive, i.e.,

\[
x^*(N) \in \text{int } \mathcal{X}, \nu^*(N) \in \text{int } \mathcal{U}, \quad x^*(N+1) \in \text{int } \mathcal{T} \subseteq \text{int } \mathcal{X}. \quad \text{(31)}
\]

By the same arguments as for (27) we have

\[
x^*(N+l) \in \text{int } \mathcal{T} \subseteq \text{int } \mathcal{X} \quad \text{ for all } l \geq 0. \quad \text{(32)}
\]

Together and imply that for horizon and initial condition has the same solution as the unconstrained infinite-horizon problem. Consequently, \(x^*(N) \in \mathcal{T}\), since \(\mathcal{T}\) is the largest set of initial conditions such that and the unconstrained problem result in the same solution. Since \(x^*(N) \in \mathcal{T}\), the input sequence and trajectory

\[
\nu^*(N) = K_\infty x^*(N) \in \mathcal{U}. \quad \text{(30)}
\]
with initial condition \( x(0) \) are feasible for horizon \( N \) and \( u^*(N) = K_{\infty} x^*(N) \).

We need to show \( x^*(N) \in \text{int} \, \mathcal{T} \) to complete the proof, which can be done by showing the existence of an open ball centered at \( x^*(N) \) in \( \mathcal{T} \). This requires three preparations. First note that \( x^*(N+1) \in \text{int} \, \mathcal{T} \) implies there exists an \( \epsilon > 0 \) such that

\[
B_{\epsilon_1}(x^*(N+1)) \subset \mathcal{T}. \tag{33}
\]

By the definition of \( \mathcal{T} \) in (2) we have

\[
(A + BK_{\infty})^k \xi \in \mathcal{X}_l \forall k \geq 0, \xi \in B_{\epsilon_1}(x^*(N+1)) \tag{34}
\]

Secondly, \( u^*(N) \in \text{int} \, \mathcal{U} \) and \( x^*(N) \in \text{int} \, \mathcal{X} \) imply there exist \( \epsilon_2 > 0 \) and \( \epsilon_3 > 0 \) such that \( B_{\epsilon_2}(u^*(N)) \subset \mathcal{U} \) and \( B_{\epsilon_3}(x^*(N)) \subset \mathcal{X} \). Moreover, \( \epsilon_3 \) can be chosen sufficiently small to ensure \( K_{\infty} B_{\epsilon_3}(x^*(N)) \subset B_{\epsilon_2}(u^*(N)) \subset \mathcal{U} \), because \( x \rightarrow K_{\infty}x \) is linear. Together \( B_{\epsilon_3}(x^*(N)) \subset \mathcal{X} \) and \( K_{\infty} B_{\epsilon_3}(x^*(N)) \subset \mathcal{U} \) yield

\[
B_{\epsilon_3}(x^*(N)) \subset \mathcal{X}_l \tag{35}
\]

by definition of \( \mathcal{X}_l \) (see (2)). As a third preparation, note that \( \epsilon_3 \) can be chosen sufficiently small to ensure

\[
(A + BK_{\infty}) B_{\epsilon_3}(x^*(N)) \subset B_{\epsilon_1}(x^*(N+1)) \tag{36}
\]

because \( x \rightarrow (A + BK_{\infty})x \) is linear. By collecting intermediate results we find, for all \( \xi \in B_{\epsilon_3}(x^*(N)) \),

\[
(A + BK_{\infty})^0 \xi = \xi \in \mathcal{X}_l \quad \text{(acc. to (35))}
\]

\[
(A + BK_{\infty})^1 \xi \in \mathcal{X}_l \quad \text{(acc. to (36), (34))}
\]

\[
(A + BK_{\infty})^2(A + BK_{\infty})^l \xi \in \mathcal{X}_l \forall l \geq 0 \quad \text{(acc. to (36), (34))}
\]

Together these three statements imply \( B_{\epsilon_3}(x^*(N)) \subset \mathcal{T} \) by definition of \( \mathcal{T} \) in (2), or equivalently, \( x^*(N) \in \text{int} \, \mathcal{T} \). This proves \( x(0) \) results in the active set (23) for horizon \( N \). Furthermore, \( x^*(N) \in \text{int} \, \mathcal{T} \) implies that (6) applies. Consequently, (26) is also the optimal solution for horizon \( N \).

\[\tag*{\square}\]

It remains to show that the active sets (23) and (24) define the same polytope and the same optimal solution on it. We call polytopes with this property persistent.

\[\textbf{Definition 5.} \text{A polytope } \mathcal{P} \text{ and the optimal solution on it are called persistent from horizon } N \text{ on, if the polytope remains the same for all initial conditions } x(0) \in \mathcal{P} \text{ and all } l \geq 0.\]

We omit "from horizon \( N \) on" when \( N \) is obvious. Note that \( N \) is not necessarily the smallest possible one in the definition. The term "persistent active set" refers to any active set that defines a persistent polytope.

\[\textbf{Proposition 6.} \text{Assume the conditions stated in Lemma 4 to hold. Then the polytope } \mathcal{P} \text{ and solution on it defined by the active set (27) are persistent from horizon } N \text{ on. Furthermore, for any horizon } N + l, \quad l \geq 0 \text{ and the optimal solution on it are defined by the active set (24).} \]

\[\begin{proof}
\text{Proof. Let } l \geq 0 \text{ be arbitrary and let } \mathcal{P}_N \text{ and } \mathcal{P}_{N+l} \text{ refer to the polytopes defined by the active sets (23) and (24), respectively. Any } x(0) \text{ with active set (23) for horizon } N \text{ results in the active set (24) for horizon } N + l \text{ according to the first part of the proof of Lemma 4. This implies } \mathcal{P}_N \subseteq \mathcal{P}_{N+l}. \text{ Analogously, the second part of the proof implies } \mathcal{P}_{N+l} \subseteq \mathcal{P}_N. \text{ The proof of Lemma 4 also established the equality of the input sequences and optimal trajectories (26) for all } x(0) \in \mathcal{P}_N = \mathcal{P}_{N+l}. \quad \Box
\end{proof}\]

\[\text{Example 7. Consider the same problem as in Example 3. The white polytopes in Figure 3 are defined by the active sets (23) and (24), respectively. Any } x(0) \text{ with active set (23) for horizon } N \text{ results in the active set (24) for horizon } N + l \text{ according to the first part of the proof of Lemma 4. This implies } \mathcal{P}_N \subseteq \mathcal{P}_{N+l}. \text{ Analogously, the second part of the proof implies } \mathcal{P}_{N+l} \subseteq \mathcal{P}_N. \text{ The proof of Lemma 4 also established the equality of the input sequences and optimal trajectories (26) for all } x(0) \in \mathcal{P}_N = \mathcal{P}_{N+l}. \quad \Box
\]

\[\begin{array}{ccc}
N = 1 & N = 2 \\
\hline
000000.0000 & 000000.00000000.0000 \\
100000.0000 & 100000.00000000.0000 \\
010000.0000 & 010000.00000000.0000 \\
\end{array}\]

which are persistent polytopes from \( N = 1 \) and \( N = 2 \) on, respectively, according to Proposition 6.

\[\text{The two red polytopes for } N = 1 \text{ shown in Figure 3 result for the active sets}
\]

\[000000.0001 \quad 000000.0010\]
which do not respect the conditions of Proposition 1. Figure 3 shows that they are not persistent but disappear for $N = 2$.

The light grey polytopes in Figure 3 are defined by the active sets

\begin{align*}
000000.00000.00000 & \\
100000.00000.00000 & \\
010000.00000.00000 & \\
000000.010000.00000 & \\
100000.010000.00000 & \\
010000.010000.00000 &
\end{align*}

for $N = 2$. These polytopes are persistent from $N = 2$ on according to Proposition 2.

The dark grey polytopes in Figure 3 are defined by the active sets

\begin{align*}
100000.00000.00001 & \\
010000.00000.00100 & \\
000000.010000.00100 & \\
000000.100000.00001 &
\end{align*}

for $N = 2$. An analysis of the example for $N = 3$ (not detailed here) shows that the polytopes defined by (37) and (38) are indeed persistent from $N = 2$ on and not persistent, respectively.

Finally, Figure 3 shows the solution to (1) for a sample initial condition for $N = 1$ and $N = 2$. The two trajectories illustrate that optimal trajectories change if the horizon is increased for initial conditions from non-persistent polytopes (cp. remark (ii) in the notation section). Moreover, $x^*(N) \in \partial T$ results for $N = 1$, and since the trajectories for $N = 1$ and $N = 2$ differ, this shows $x^*(N) \in \mathcal{T}$ is not sufficient in (5) and Lemma 4.

Lemma 4 and Proposition 6 essentially result from inserting zeroes, i.e., stages with inactive constraints, "on the right" of an active set of the form (23). Just as in Corollary 2 we can also remove stages "on the left" to obtain new active sets. In general this results in active sets for a shrinking horizon as in Corollary 2. For persistent active sets (23), new active sets for the same horizon result, and they are persistent themselves:

**Corollary 8.** Assume $\mathcal{P}$ is a polytope that is persistent from horizon $N$ on with an active set $\alpha_N$ of the form (23). Let $\alpha_{N,i}$ be tuples of length $q_X + q_U$ such that

$$
\alpha_N = \alpha_{N,0} \cdots \alpha_{N,N-1} \underbrace{0 \cdots 0}_{\overbrace{q_T}}.
$$

Then the polytope defined by

$$
\alpha_{N-l} = \alpha_{N,l} \cdots \alpha_{N,N-1} \underbrace{0 \cdots 0}_{\overbrace{q_T}}
$$

is persistent from $N-l$ on for any $l \in \{0, \ldots, N-1\}$. Moreover, for any such $l$, the polytope defined by (40) for horizon $N-l$ is defined by

$$
\tilde{\alpha}_N = \alpha_{N,l} \cdots \alpha_{N,N-1} \underbrace{0 \cdots 0}_{\overbrace{l \cdot (q_X + q_U)}} \underbrace{0 \cdots 0}_{\overbrace{q_T}}
$$

for horizon $N$ and persistent from horizon $N$ on.

**Proof.** Let $x(0) \in \mathcal{P}$ be arbitrary and let $u^*(k)$, $x^*(k)$, $k \geq 0$ be as in (41). According to Corollary 2 the active set (40) defines the optimal solution and polytope for $x^*(l)$. According to Proposition 6 the
active set \([40]\) defines a polytope that is persistent from horizon \(N - l\) on, therefore it is persistent from \(N\) on. The claim about \(41\) follows by applying Lemma \(4\) to \((40)\).

It is evident from Figure \(2\) that the set of persistent polytopes (white and yellow polytopes in the top figure) is in general not convex. The following two corollaries summarize some other properties of the set of persistent polytopes with active sets \((23)\).

**Corollary 9.** Let \(P_N\) refer to the union of all persistent polytopes with active sets of the form \((23)\). \(P_N\) is positive invariant under the open-loop optimally controlled system, i.e., \(x(k + 1) = Ax(k) + Bu^*(k)\) with \(u^*(k)\) as introduced in \([4]\). Furthermore, \(P_N\) is in general not convex, but its convex hull is a subset of \(F_N\).

**Proof.** Let \(x(0) \in P_N\) be arbitrary and let \(\alpha_N\) be the active set for \(x(0)\). Since \(\alpha_N\) has the form \((23)\), it can be partitioned as in \((39)\). According to Corollary \(2\) the active set \((10)\) defines the optimal solution and polytope for \(x^*(l)\), where \(x^*(l)\) is as in \((4)\). Since \(\alpha_{N-l}\) defines a polytope that is persistent from \(N\) on according to Corollary \(8\) we have \(x^*(l) \in P_N\) for all \(l \geq 0\), which proves the first claim. The second claim holds, because \(F_N\) is convex \([3]\) and for every convex set \(S\) and every subset \(S' \subseteq S\) thereof, the convex hull of \(S'\) is contained in \(S\).

All statements made so far apply to the open-loop optimal input sequences and trajectories. Corollary \(10\) also makes a statement about their use on a receding horizon, i.e., about model predictive control (MPC). Let \(x \rightarrow u^{\text{MPC}}(x), u^{\text{MPC}} : F_N \rightarrow \mathbb{R}^m\) refer to the feedback law that results from applying the first \(m\) elements of \(u^*_N : F_N \rightarrow \mathbb{R}^m\). We stress \((42)\) does not hold on \(F_N\) in general (see remark (ii) in the notation section), but multiple problems \((1)\) have to be solved to determine the MPC input signal sequence in general.

**Corollary 10.** Let \(P_N\) be defined as in Corollary \(4\). For every \(x(0) \in P_N\), the open-loop optimal input sequence that solves \((1)\) is equal to the one that results in MPC, i.e.,

\[
u^*(k) = u^{\text{MPC}}(x^*(k)), \quad k \geq 0, \quad (42)\]

for \(u^*(k)\) and \(x^*(k)\) as introduced in \([4]\). Furthermore, \(P_N\) is positive invariant under MPC.

**Proof.** Let \(x(0) \in P_N\) be arbitrary, let \(\alpha_N\) be the active set for \(x(0)\) and let \(u^*(k), x^*(k), k \geq 0\) be as in \((4)\). By the same arguments as in the proof of Corollary \(9\) \(\alpha_N\) has the form \((39)\). \(\alpha_{N-l}\) as in \((40)\) defines the optimal solution and polytope for \(x^*(l)\) for all \(l \in \{0, \ldots, N\}\), and this polytope is persistent from \(N\) on. This implies \(u^*(l)\) is the first optimal input signal for \((1)\) with horizon \(N\) and initial \(x^*(l)\), which yields \(u^{\text{MPC}}(x) = K_\infty x\) for all \(x \in T\) and all open-loop optimal input signals are equal to the unconstrained solution on \(T\), i.e., \(u^*(k) = K_\infty x^*(k)\), \(x^*(k + 1) = (A + BK_\infty) x^*(k)\) for all \(k > 0\) and all \(x(0) \in T\). Combining \((42)\) and Corollary \(9\) obviously yields the positive invariance of \(P_N\) under MPC.

The statements made so far focused on active sets. Some implied statements on the polytopes are collected in Remark \(11\) below. Two types of relations are interesting in particular: Active sets for different horizons that define geometrically equal polytopes (the persistent polytopes, see part (ii) of Remark \(11\)). Secondly, we are interested in sequences of active sets and polytopes that result for the optimally steered system (part (iii) of Remark \(11\)). The latter essentially extend statements on state trajectories to trajectories of polytopes. For clarity, let \(x^*(k; x(0), N)\) refer to \(x^*(k)\) for initial condition \(x(0)\) and horizon \(N\) in Remark \(11\) where \(x^*(k)\) is as defined in \((4)\).

**Remark 11.** (i) **Proposition 7** and Corollary 2 relate active sets for shrinking horizons \(N, N - 1, \ldots\), that result from removing stages at the beginning of the horizon. The corresponding polytopes are in general not related geometrically, but dynamically. Specifically, applying the optimal input signals maps \(P(\alpha_N)\) into \(P(\alpha_{N-1}), P(\alpha_{N-1})\) into \(P(\alpha_{N-2})\) etc., i.e.,

\[
x^*(l; x(0), N) | x(0) \in P(\alpha_{N-l+1}) \subseteq P(\alpha_{N-l}) \quad (43)\]

for all \(l \in \{1, \ldots, N - 1\}\). The resulting active sets \(\alpha_{N-1}, \alpha_{N-2}, \ldots\) and polytopes \(P(\alpha_{N-1}), P(\alpha_{N-2}), \ldots\) are not defined for horizon \(N\), but for the shrinking horizon.
The case for the set notation, since the introduction immediately evident from the bit tuples (22), this is not a problem has been found, since (see (45) below).

(ii) Lemma 6 and Proposition 6 discuss a subset of active sets for growing horizons \( N, N + 1, \ldots \) that result from inserting inactive stages from the end of the horizon. The resulting active sets all define the geometrically same polytope. Specifically,

\[
P(\alpha_N) = P(\alpha_{N+1})
\]

for all \( l \geq 0 \), where \( \alpha_N \) and \( \alpha_{N+1} \) refer to the sets in (23) and (24), respectively.

(iii) Corollary 8 combines the operations from (i) and (ii). The resulting sequence of polytopes is the optimal sequence from (i) that obeys the inclusion property (43). In contrast to (i), however, the new active sets \( \alpha_N \) (see (11)) are persistent and thus defined for horizon \( N \) under the conditions of Corollary 8.

3 Some computational aspects

A simple criterion for the persistency of polytopes is of obvious interest, since it enables us to detect that the infinite-horizon solution has been found for a polytope by solving the simpler finite-horizon problem. If all polytopes are persistent for some \( N \), \( P_N = F_N \) and the solution to the infinite-horizon problem has been found, since \( F_N = F_{N+l} \) for all \( l \geq 0 \). A finite \( N \) such that \( P_N = F_N \) does not always exist (see, e.g., [14]), however. In this case \( P_N \) characterizes the largest region for which the solution to the infinite-horizon problem has been found. \( P_N \) is defined by the active sets (23) in a lean fashion. By exploiting its positive invariance, the number of active sets required to characterize \( P_N \) can be reduced further (see (45) below).

The forward constraint order [9] arises in backward dynamic programming and therefore is an obvious choice. The backward order, i.e., the order that results from reversing the sequence of lines in [9], may be more useful in computations. For example, the bit tuples (22) in Example 3 correspond to the index sets \{1\}, \{1\}, \{1,7\} and \{2,7\} according to rule 8. While the relation of the active sets is immediately evident from the bit tuples (22), this is not the case for the set notation, since the introduction of the additional stage for \( N = 2 \) shifts all indices by \( q_X + q_T = 6 \). If the backward constraint order is used, the bit tuples and index sets that correspond to (22) read

\[
\begin{align*}
0000.000000.000000 & \{5\} \\
0000.100000.000000 & \{5\} \\
0000.100000.100000 & \{5,11\} \\
0000.100000.010000 & \{5,12\}
\end{align*}
\]

and their relation is obvious in both notations. The statements of the paper carry over to the backward order in an obvious fashion. For example, the \( q_T \) trailing zeros in all statements in Section 2.2 and (22) become \( q_T \) leading zeros in the corresponding statements and (44) for the backward order. Note that the order of constraints within each stage must be fixed but is irrelevant.

Corollary 8 suggests to determine and store the outmost persistent polytopes and to determine the remaining persistent polytopes with simple bit shifting operations. More precisely, assume all active sets of the form

\[
\alpha_N = \alpha_{N,0} \cdots \alpha_{N,N-1} \underbrace{0 \cdots 0}_{\#0 \cdots 0} q_T
\]

where the \( \alpha_{N,i} \), \( i = 0, \ldots, N - 2 \) are arbitrary tuples (possibly \( 0 \cdots 0 \)) of length \( q_X + q_T \). According to Corollary 8 the active sets

\[
\alpha_{N,i} \cdots \alpha_{N,N-1} \underbrace{0 \cdots 0}_{l-(q_X+q_T)} q_T
\]

can be generated for each (45) and define persistent polytopes. They define a trajectory of polytopes for the initial polytope (45) according to part (iii) of Remark 11 that leads to \( \mathcal{T} \). Combining \( \mathcal{T} \) and all polytopes defined by (45) and (46) yields the subset of persistent polytopes \( P_N \subseteq F_N \). Since the active sets (46) are constructed by simple bit shifting operations, this is a computationally attractive approach to constructing \( P_N \) from the sets (15). The active sets (45) can be determined by solving linear programs [9]. We claim without giving details that the proposed approach results in a particular depth-first analysis of the active set tree first proposed in [9].
4 Conclusions and future work

We uncovered a certain structure of the set of active sets that define the solution to the constrained linear quadratic regulator. While the set of active sets and the set of affine pieces and polytopes are equally useful in that both define the solution of the same optimal control problem, the structure of the former revealed here is not immediately evident in the latter. We therefore claim the structure of the set of active sets is interesting and important per se. This is corroborated by the fact that very simple operations (such as deleting bit tuples that represent a stage, or inserting zeroes for another stage) suffice to generate the active sets that define the persistent part of the geometric solution, i.e., the persistent affine pieces and polytopes. More practically, the structure of the set of active sets is useful, for example, for an analysis and a lean characterization of those parts of the solution that are independent of the horizon $N$, which after all is a nuisance parameter in optimal control Problem (where ”independence” is understood as in Definition 5).

Future work will address the extension to nonlinear optimal control problems and investigate the computational aspects summarized in Section 3.

Appendix

Lemma 12 is used in the proof of Lemma 4 for $S = T$ and $\hat{A} = A + BK_\infty$.

Lemma 12. Let $S \subset \mathbb{R}^n$ be a compact set. If $S$ is positive invariant for the $n$-dimensional system $x(k+1) = \hat{A}x(k)$, then the following statements hold:

1. For any $\lambda \in (0, 1)$, the set $\lambda S = \{\lambda \xi | \xi \in S\}$ is positive invariant.

2. The interior of $S$ is positive invariant.

Proof. Let $\lambda \in (0, 1)$ be arbitrary. Let $\zeta \in \lambda S$ be arbitrary, then there exists an $\xi \in S$ such that $\zeta = \lambda \xi$ by definition of $\lambda S$. Since $S$ is positive invariant, $\xi \in S$ implies $\hat{A}\xi \in S$, which implies $\lambda \hat{A}\xi = \lambda S$. Combining this with $\lambda \hat{A}\xi = \hat{A}\lambda \xi = \hat{A}\zeta$ yields $\zeta \in \lambda S$. Since $\lambda \in (0, 1)$ and $\zeta \in \lambda S$ were arbitrary, the first claim holds. The second claim follows, since, for any $\xi \in \text{int} S$ there exists a $\lambda \in (0, 1)$ such that $\xi \in \lambda S$ and $\lambda S \subset \text{int} S$. □
