Abstract—This paper reports an effort to consolidate numerous coherence-based sparse signal recovery results available in the literature. We present a single theory that applies to general Hilbert spaces with the sparsity of a signal defined as the number of (possibly infinite-dimensional) subspaces participating in the signal’s representation. Our general results recover uncertainty relations and coherence-based recovery thresholds for sparse signals, block-sparse signals, multi-band signals, signals in shift-invariant spaces, and signals in finite unions of (possibly infinite-dimensional) subspaces. Moreover, we improve upon and generalize several of the existing results and, in many cases, we find shortened and simplified proofs.

I. INTRODUCTION

The sparse signal recovery literature is vast and has evolved along several threads with recent focus mostly on probabilistic results. This paper constitutes an attempt to consolidate the numerous coherence-based recovery results available in the literature. More specifically, we formulate a single theory that applies to finite- and infinite-dimensional Hilbert spaces, in combination with sparsity defined as the (finite) number of (possibly infinite-dimensional) subspaces participating in a signal’s representation. The general coherence-based recovery thresholds we find contain the known thresholds in the following settings as special cases: (i) sparse signals in finite-dimensional spaces [11–13], (ii) block-sparse signals [5, 6], (iii) multi-band signals [7–9], (iv) signals in shift-invariant spaces [10], and (v) signals in finite unions of finite or infinite-dimensional subspaces [11–13]. In addition, we improve upon the thresholds in [5] and we generalize the uncertainty relation in [10]. We introduce suitable generalizations of P0-minimization [2], basis pursuit [2], and orthogonal matching pursuit [14]. Finally, we indicate how the results on signal separation reported in [15], [16] can be extended to the general Hilbert space setting considered here.

Key to our results are definitions of coherence [2] and mutual coherence [3, 16] that work for our general setting. Based on these definitions, we obtain a general kernel uncertainty relation which is then used to establish general recovery thresholds. Similarly our definition of mutual coherence paves the way to a general uncertainty relation that yields fundamental limits on how sparse a signal in a general Hilbert space can be under two different representations. All theorems in this paper are given without proof.

Notation: Lowercase boldface letters stand for column vectors and uppercase boldface letters designate matrices. For a vector $\mathbf{a}$, the $k$th element is written $a_k$. For the matrix $\mathbf{A}$, $\mathbf{A}^H$ is its conjugate transpose, its $k$th column is written $\mathbf{a}_k$, and the entry in the $k$th row and $l$th column is denoted by $A_{k,l}$. The spectral norm of $\mathbf{A}$ is $\|\mathbf{A}\|_{2 \rightarrow 2}$, $\sigma_{\min}(\mathbf{A})$ and $\sigma_{\max}(\mathbf{A})$ are the minimum and maximum singular value of $\mathbf{A}$, respectively. $\mathcal{H}$ and $\mathcal{G}$ are Hilbert spaces equipped with the norm $\|\cdot\|_{\mathcal{H}}$ and $\|\cdot\|_{\mathcal{G}}$, respectively, and $\mathcal{H}$ has direct sum decomposition [17, Ch. 5.20] $\mathcal{H} = \bigoplus_{i=1}^{n} \mathcal{H}^{(i)}$ where $n < \infty$. We define $\nu(i)$ to be the canonical projection of $\nu$ onto $\mathcal{H}^{(i)}$. For $\nu \in \mathcal{H}$, $\|\nu\|_{\mathcal{H},0} \triangleq \{|i : \nu(i) \neq 0\}$ and $\|\nu\|_{\mathcal{H},\infty} \triangleq \sum_{i=1}^{n} |\nu(i)|_{\mathcal{H}}$. We define $\mathcal{H}^{(S)} \triangleq \bigoplus_{\omega \in S} \mathcal{H}^{(\omega)}$ and $\nu^{(S)}$ to be the projection of $\nu$ onto $\mathcal{H}^{(S)}$. We say that a signal $\nu \in \mathcal{H}$ is $\varepsilon_S$-concentrated to the set $S$ if $\|\nu^{(S)}\|_{\mathcal{H},1} \geq (1-\varepsilon_S)\|\nu\|_{\mathcal{H},1}$, where $0 \leq \varepsilon_S \leq 1$. We define $e_i \in \mathbb{C}^N$ to be the all zero vector with a one in the $i$th position. For an operator $\varphi : \mathcal{H} \rightarrow \mathcal{G}$ with adjoint $\varphi^H$, $\omega_{\min}(\varphi) \triangleq \inf_{\nu \in \mathcal{H}} \|\varphi(\nu)/\|\nu\|_{\mathcal{H}}$, $\omega_{\max}(\varphi) \triangleq \sup_{\nu \in \mathcal{H}} \|\varphi(\nu)/\|\nu\|_{\mathcal{H}}$, and $\ker(\varphi) \triangleq \{\nu \in \mathcal{H} : \varphi(\nu) = 0\}$. For $\alpha \in \mathbb{R}$, we set $|\alpha|^+ \triangleq \max\{0, \alpha\}$. The cardinality of a set $S$ is denoted as $|S|$. The Fourier transform operator is written $\mathcal{F}$.

II. SIGNAL AND SAMPLING MODEL

Let $\mathcal{H}$ and $\mathcal{G}$ be Hilbert spaces, with dimensions $N$ and $M$, respectively, possibly infinite. Assume that $\mathcal{H} = \bigoplus_{i=1}^{n} \mathcal{H}^{(i)}$, $n < \infty$, and set $d_i = \dim(\mathcal{H}^{(i)})$. We describe the sampling of signals in $\mathcal{H}$ through the application of a bounded linear operator $\Phi : \mathcal{H} \rightarrow \mathcal{G}$, which we call a sampling operator. With $\Phi$ we associate the operators $\varphi_i : \mathcal{H}^{(i)} \rightarrow \mathcal{G}$, for $i = 1, \ldots, n$, obtained by restricting the action of $\Phi$ to the subspace $\mathcal{H}^{(i)}$. It follows from the linearity of $\Phi$ that $\Phi(\nu) = \sum_{i=1}^{n} \varphi_i(\nu(i))$. We require that each $\varphi_i$ be injective.

For $N = \sum_{i=1}^{n} d_i < \infty$, the action of $\Phi$ can be represented through a matrix $\mathbf{D} \in \mathbb{C}^{M \times N}$ according to $\Phi(\nu) = \mathbf{D}\nu$, $\nu \in \mathbb{C}^N$. Taking $\mathbf{D} i = [d_{i,1}, \ldots, d_{i,n}]$ to be the set of columns of $\mathbf{D}$ that correspond to $\mathcal{H}^{(i)}$ we have $\varphi_i(\nu(i)) = \mathbf{D}_i \nu(i)$, for $i = 1, \ldots, n$.

III. DEFINITIONS OF COHERENCE

Key to our results are definitions of coherence, mutual coherence, and spark for general sampling operators.

Definition 1 (Hilbert space coherence): Let $\mathcal{H}$ and $\mathcal{G}$ be Hilbert spaces and let $\Phi : \mathcal{H} \rightarrow \mathcal{G}$ be a sampling operator. We define the Hilbert space coherence of $\Phi$ as

$$\mu_{\mathcal{H}} = \mu_{\mathcal{H}}(\Phi) \triangleq \max_{i,j, i \neq j} \frac{\omega_{\max}(\varphi_i^H \varphi_j)}{\omega_{\min}(\varphi_j^H \varphi_i)}.$$  \hfill (1)\footnote{By assumption the operators $\varphi_i$ are injective, hence $\omega_{\max}(\varphi_i) > 0$.}
We can interpret $\mu_{\mathcal{H}}(\Psi)$ as a measure of closeness of the subspaces $\mathcal{H}^{(i)}$ under the action of $\Phi$.

**Definition 2 ( Mutual Hilbert space coherence):** Let $\mathcal{H}_1$, $\mathcal{H}_2$, and $\mathcal{G}$ be Hilbert spaces and let $\Phi: \mathcal{H}_1 \rightarrow \mathcal{G}$ and $\Psi: \mathcal{H}_2 \rightarrow \mathcal{G}$ be sampling operators. We define the mutual Hilbert space coherence of $\Phi$ and $\Psi$ as

$$
\mu_{\mathcal{H}}(\Phi, \Psi) \triangleq \max_{i,j} \frac{\omega_{\max}(\varphi_i^H \varphi_j)}{\omega_{\min}(\varphi_i) \omega_{\min}(\varphi_j)}.
$$

(2)

The mutual Hilbert space coherence extends the definition of mutual coherence in [3], [16]. The setting of [3], [16] is recovered as follows. Let $\mathcal{H}_1 = \mathbb{C}^N_1$, $\mathcal{H}_2 = \mathbb{C}^N_2$, and $\mathcal{G} = \mathbb{C}^M$. Represent the sampling operators $\Phi: \mathcal{H}_1 \rightarrow \mathcal{G}$ and $\Psi: \mathcal{H}_2 \rightarrow \mathcal{G}$ by the matrices $A$ and $B$, respectively, so that $\Phi(v) = Av$ and $\Psi(u) = Bu$. Then, we have

$$
\mu_{\mathcal{H}}(\Phi, \Psi) = \max_{i,j} \frac{|a_i^H b_j|}{|a_i|_2 |b_j|_2} \leq \alpha \max_{i,j} |a_i, b_j| = \mu_m,
$$

where $\mu_m$ is the mutual coherence as specified in [16], and (a) follows since in [16] $A$ and $B$ are assumed to have columns with unit $\ell_2$-norm.

We will also need a general definition of spark [4], [18].

**Definition 3 (Hilbert space spark):** Let $\mathcal{H}$ and $\mathcal{G}$ be Hilbert spaces and let $\Phi: \mathcal{H} \rightarrow \mathcal{G}$ be a sampling operator. Then

$$
\spark(\Phi) \triangleq \min_{v \in \ker(\Phi) \setminus \{0\}} \|v\|_{\mathcal{H},0}.
$$

(3)

The spark of a sampling operator is the smallest number of subspaces that a non-zero signal $v \in \mathcal{H}$ in $\ker(\Phi)$ can occupy.

**IV. RECOVERY THRESHOLDS**

With our general definitions of coherence and spark, the general recovery thresholds below follow without difficulties. We start with a general kernel uncertainty relation.

**Theorem 1 (Kernel uncertainty relation):** Let $\Phi: \mathcal{H} \rightarrow \mathcal{G}$ be a sampling operator with Hilbert space coherence $\mu_{\mathcal{H}}(\Phi)$. Let $v \in \mathcal{H}$ be $\varepsilon_S$-concentrated to $S$. If $\Phi(v) = 0$, then

$$
|S| \geq (1 - \varepsilon_S) \left(1 + \left(\mu_{\mathcal{H}}(\Phi)^{-1}\right)^{-1}\right).
$$

(4)

We next define two optimization problems for the recovery of a signal $v \in \mathcal{H}$ from its measurements $z = \Phi(v) \in \mathcal{G}$. The first one, $\mathcal{H}$-P0, aims to find the signal that explains the given measurements while occupying the fewest subspaces:

$$(\mathcal{H}$-P0) \text{ minimize } \|\hat{v}\|_{\mathcal{H},0} \text{ subject to } \Phi(\hat{v}) = z.
$$

(5)

Furthermore, we consider a modified version of basis pursuit:

$$(\mathcal{H}$-BP) \text{ minimize } \|\hat{v}\|_{\mathcal{H},1} \text{ subject to } \Phi(\hat{v}) = z.
$$

(6)

Recovery thresholds for $\mathcal{H}$-P0 and $\mathcal{H}$-BP can now be derived from the kernel uncertainty relation in Theorem 1.

**Theorem 2:** If $v \in \mathcal{H}$ satisfies $\Phi(v) = z$ and

$$
\|v\|_{\mathcal{H},0} < \spark(\Phi)/2,
$$

then $v$ is the unique minimizer of $\mathcal{H}$-P0 applied to $z$.

In addition, we have the following bound, $\spark(\Phi) \geq 1 + (\mu_{\mathcal{H}}(\Phi))^{-1}$, which combined with Theorem 2 allows us to conclude that $\mathcal{H}$-P0 returns the correct solution if

$$
\|v\|_{\mathcal{H},0} \leq \left(1 + (\mu_{\mathcal{H}}(\Phi))^{-1}\right)/2.
$$

(8)

We next provide a recovery condition for $\mathcal{H}$-BP.

**Theorem 3:** If $v \in \mathcal{H}$ satisfies $\Phi(v) = z$ and (8) holds, then $\mathcal{H}$-BP applied to $z$ returns the correct solution $v$.

A commonly used alternative to BP is orthogonal matching pursuit (OMP) [14], [19]. We next present a Hilbert-space version of OMP, which we call $\mathcal{H}$-OMP. This algorithm works by iteratively identifying the subspaces $\mathcal{H}^{(1)}$ participating in the representation of $v$ and computes an approximation to $v$, denoted as $v_i$, in the $i$th iteration. The corresponding residual in the $i$th iteration is given by $r_i \triangleq z - \Phi(v_i)$. The algorithm is initialized with $r_0 \leftarrow z$ and $i \leftarrow 1$, and performs the following steps until $\|r_i\|_{\mathcal{H},0} = 0$:

1) Find

$$
\ell = \arg \max_{\ell} \|\hat{v}_{\ell}^H (r_{i-1})\|_{\mathcal{H}}/\omega_{\min}(\varphi_{\ell}).
$$

2) Update the list of participating subspaces: $S_i \leftarrow S_{i-1} \cup \{\ell\}$.

3) Find the best approximation to $v$ with support $S_i$:

$$
v_i \leftarrow \arg \min_{u \in \mathcal{H}\{s_i\}} \|z - \Phi_S(u)\|_{\mathcal{H}}.
$$

4) Update the residual and $i$: $r_i \leftarrow z - \Phi(v_i)$, $i \leftarrow i + 1$.

**Theorem 4:** Let $\Phi: \mathcal{H} \rightarrow \mathcal{G}$ be a sampling operator. Then $\mathcal{H}$-OMP applied to $z = \Phi(v)$ returns the correct solution $v$ if (8) is satisfied and will require exactly $\|v\|_{\mathcal{H},S}$ iterations.

Note that implementing the algorithms mentioned above, when $\mathcal{H}$ is infinite-dimensional, is non-trivial. Some alternatives to $\mathcal{H}$-BP and $\mathcal{H}$-OMP, such as SBR/2/4, have been proposed for blind multi-band sampling [2], which is a special case of our setup. It is an interesting open problem to extend these algorithms to the general framework in this paper.

**V. DISCUSSION OF RECOVERY THRESHOLDS**

We next show how the recovery thresholds in [1]–[5], [7]–[9], [11] follow from the general recovery threshold (8). The results in [6], which pertain to a generalization of [5] allowing for different subspace dimensions, can be recovered following the same methodology, but this will not be detailed here due to space constraints.

**A. Sparse signal recovery**

The (coherence-based) thresholds in [11]–[14] are recovered as follows. Set $\mathcal{H} = \mathbb{C}^N$ and $\mathcal{G} = \mathbb{C}^M$. Take the sampling operator $\Phi$ to be represented by the matrix $D \in \mathbb{C}^{M \times N}$, with unit $\ell_2$-norm columns $d_i$. Take $\mathcal{H}^{(i)}$ to be the 1-dimensional subspace spanned by $e_i \in \mathbb{C}^N$, so that $N = n_i$. The action of $\varphi_i: \mathcal{H}^{(i)} \rightarrow \mathcal{G}$ is represented by $\varphi_i(v^{(i)}) = d_i v^{(i)}$. Since $\omega_{\min}(\varphi_i) = \|d_i\|_2 = 1$ and $\omega_{\max}(\varphi_i,\varphi_j) = \|d_i, d_j\|_2$, we get $\mu_{\mathcal{H}} = \max_{i \neq j} \|d_i, d_j\|$, which is exactly the definition of coherence as introduced in [1]–[3]. The recovery threshold for $\mathcal{H}$-P0, $\mathcal{H}$-BP, and $\mathcal{H}$-OMP (which then reduce to P0, BP, and OMP, respectively) is thus equal to the
corresponding thresholds in [2]–[4]. As an aside the general result [8] shows how dictionaries with unnormalized columns should be treated, specifically what the appropriate measure of coherence is, and what the selection criterion in Step 1 of (\(\mathcal{H}\)-)OMP should be.

### B. Block-sparsity

The results for the block-sparse setting considered in [5] are recovered as follows. Set \(\mathcal{H} = \mathbb{C}^N, \mathcal{G} = \mathbb{C}^{M},\) and \(N = nd,\) where \(d\) is the block size and \(n\) is the number of blocks (and hence the number of subspaces \(\mathcal{H}^{(i)}\)). As before, the sampling operator \(\Phi\) is represented by the matrix \(D \in \mathbb{C}^{M \times N}\) with unit \(\ell_2\)-norm columns. Let \(\mathcal{H}^{(i)}\) be the subspace spanned by \(\{e_{(i-1)d+1}, \ldots, e_{id}\},\) and set \(D_i = [d_{(i-1)d+1} \cdots d_{id}]\), so that \(\varphi_i(v^{(i)}) = D_i v^{(i)}\). From [1] the Hilbert space coherence is

\[
\mu_{\mathcal{H}}(\Phi) = \max_{i,j \neq i} \frac{\sigma_{\max}(D_i^H D_j)}{\sigma_{\min}(D_i)^2}.
\]

We next show how the recovery threshold [8] improves upon that reported in [5] Thms. 2 and 3, which states that recovery using (L-OPT) [5, Eq. 32] and BOMP [5, Sec. IV-C. Multi-band signals] is possible when we apply the Geršgorin disc theorem [20, Th. 6.1.1] in \(\mathbb{C}^{M \times N}\) is divided into \(n\) disjoint intervals \(I_1, \ldots, I_n,\) with \(I_i = [(i-1)/(nT), i/(nT)],\) \(i = 1, \ldots, n.\) Define the subspaces \(\mathcal{H}^{(i)} = \{v \in L_2(\mathbb{R}) : V(f) = 0,\) for all \(f \notin I_i\}\). Thus, for a signal \(v \in \mathcal{H}\), the sparsity level \(\|v\|_{\mathcal{H}^{(i)}}\) is the number of frequency bands \(I_i\) occupied by \(V\).

We next demonstrate how the multi-coset sampling scheme of [7], [8] can be analyzed in our framework. Multi-coset sampling maps the signal \(v \in m\) to \(m\) sequences \(z^{(k)}\) as follows:

\[
z^{(k)}_i = v(t_i nT + kT), \quad k = 1, \ldots, m, \ell \in \mathbb{Z}.
\]

To obtain an explicit characterization of the corresponding sampling operator \(\Phi\) we will work in the frequency domain. The Fourier transform of \(z^{(k)}\) is given by

\[
Z^{(k)}(f) = \frac{1}{nT} \sum_{\ell=1}^n V(f + \ell / nT) e^{2 \pi i k \ell / n} = \frac{1}{nT} \sum_{\ell=1}^n V^{(\ell)}(f) e^{2 \pi i k \ell / n} = \sum_{\ell=1}^n \lambda_{k,\ell} V^{(\ell)}(f),
\]

where \(\lambda_{k,\ell} = (nT)^{-1} \exp(2 \pi i k \ell / n)\) and \(V^{(\ell)}(f) = V(f + \ell / nT)\). Then, the action of the sampling operator, \(\Phi: \mathcal{H} \rightarrow \mathcal{G}\), can be represented in terms of the continuously parametrized linear system of equations

\[
\begin{pmatrix}
Z^{(1)}(\ell) \\
\vdots \\
Z^{(m)}(\ell)
\end{pmatrix} = \begin{pmatrix}
\lambda_{1,1} & \lambda_{1,2} & \cdots & \lambda_{1,n} \\
\vdots & \vdots & \ddots & \vdots \\
\lambda_{m,1} & \lambda_{m,2} & \cdots & \lambda_{m,n}
\end{pmatrix} \begin{pmatrix}
V^{(1)}(\ell) \\
\vdots \\
V^{(m)}(\ell)
\end{pmatrix} = A V^{(\ell)},
\]

for \(f \in [0, 1/(nT)].\) We have thus established a finite-dimensional continuously indexed matrix representation of \(\Phi\) [7]. Based on this insight, we next show that

\[
\text{spark}(\Phi) = \text{spark}(A) = m, \quad (11)
\]

and

\[
\mu_{\mathcal{H}}(\Phi) = \mu_{\mathcal{G}}(A), \quad (12)
\]

which means that we can reduce the computation of Hilbert space sparsity and Hilbert space coherence of an infinite-dimensional operator to that of a finite matrix that does not depend on \(f\). Since (10) holds for all \(f \in [0, 1/(nT)],\) for \(v\) to lie in the kernel of \(\Phi, \tilde{V}(f)\) must be in ker(\(A\)) for each \(f \in [0, 1/(nT)].\) One can then show that this implies that \(\text{spark}(\Phi) = \text{spark}(A)\). The second equality in (11) follows since \(A\) consists of the first \(m\) rows of the \(n \times n\) DFT matrix and hence \(\text{spark}(A) = m\) [21].

To prove (12), note that for \(n \in \mathcal{H}^{(i)}\) with Fourier transform \(U, \varphi_i: \mathcal{H}^{(i)} \rightarrow \mathcal{G}\) is given by the matrix representation

\[
\varphi_i(U)(f) = \tilde{U}(f) \begin{pmatrix}
\lambda_{1,1} \\
\vdots \\
\lambda_{m,1}
\end{pmatrix}.
\]

\footnote{It is possible that \(\mu < 0\) and since \(\mu_{\mathcal{G}}(\Phi)\) is always non-negative, we do not have \(\mu_{\mathcal{H}}(\Phi) \leq \mu\) in this case. However, in this instance [5] Thms. 2 and 3 say that we cannot guarantee the recovery of any signal, but the right-hand side of (8) is positive, thus trivially improving upon the recovery thresholds in [5] Thms. 2 and 3.}
and has adjoint
\[ \varphi_i^H(X)(f) = \varphi_i^H \left( \begin{pmatrix} X^{(1)} \\ \vdots \\ X^{(m)} \end{pmatrix} \right)(f) \triangleq \left( \sum_{k=1}^{m} \lambda_i^k X^{(k)} \right)(f), \]
where
\[ X = \begin{pmatrix} X^{(1)} \\ \vdots \\ X^{(m)} \end{pmatrix} \in \mathcal{G}. \]

Hence, for \( u \in \mathcal{H}^{(t)} \) with Fourier transform \( U \), we have
\[
\| \varphi_i^H \varphi_t(U) \|_{\mathcal{G}} = \left\| \sum_{i=1}^{m} \lambda_i^j \phi_i, \ell \right\|_{\mathcal{G}} = \left\| \sum_{i=1}^{m} \lambda_i^j \phi_i, \ell \right\|_{\mathcal{G}} = \left\| U \right\|_{\mathcal{G}}, \tag{13}
\]
where \( \lambda_j \) is the \( j \)-th column of \( \Lambda \). Since (13) holds for all \( U \), it follows that
\[ \omega_{\min}(\varphi_i^H \varphi_t) = \omega_{\max}(\varphi_i^H \varphi_t) = \left| \lambda_i^j \right| \]
and hence
\[ \mu_{\mathcal{G}}(\Phi) = \max_{j, j' \neq j} \omega_{\max}(\varphi_i^H \varphi_t) = \max_{j, j' \neq j} \left| \lambda_i^H \lambda_i \right| = \mu_{\mathcal{G}}(\Lambda). \]

From [7], [9] we know that to recover a multi-band signal with bandwidth \( s/(nT) \) (and with unknown spectral occupancy), it is necessary to sample at a rate \( f_s = m/(nT) \geq 2s/(nT) \). Theorem [2] implies that uniqueness of \( \mathcal{H}^{-P0} \) recovery is guaranteed for multi-band sampling if \( \text{spark}(\Phi)/2 = m/2 > s \). Hence, sampling at rate at least \( 2s/(nT) \) is also sufficient to recover an \( s \)-sparse signal and recovery of the (multi-cost sampled) signal can be achieved through \( \mathcal{H}^{-P0} \).

D. Relation to further results

Theorem [2] in this paper implies [11] Prop. 4 and [11] Eq. (23)] with the observation that the generalized Gram matrix in [11] Eq. (17) plays the role of the sampling operator \( \Phi \) in our framework. Our Theorem [2] also implies [12] Th. 2.2).

VI. UNCERTAINTY RELATIONS AND SIGNAL SEPARATION

Another thrust in the sparse signal recovery literature deals with the recovery of sparsely corrupted signals [15]. The main tool underlying this line of work is an uncertainty relation that sets a limit on how sparsely a given signal can be represented concurrently in two different dictionaries [11], [15], [16]. We next formulate a Hilbert space version of this uncertainty relation, which is then used to recover and generalize results in [10] and [16].

Theorem 5 (Uncertainty relation): Let \( \mathcal{H}_1, \mathcal{H}_2, \) and \( \mathcal{G} \) be Hilbert spaces. and let \( \Phi: \mathcal{H}_1 \to \mathcal{G} \) and \( \Psi: \mathcal{H}_2 \to \mathcal{G} \) be sampling operators. Let \( u \in \mathcal{H}_1 \) and \( v \in \mathcal{H}_2 \) be signals that are \( \varepsilon_U \)- and \( \varepsilon_V \)-concentrated to the sets \( U \) and \( V \), respectively, and assume that \( \Phi(u) = \Psi(v) \). Then, we have
\[
\| U \|_{\mathcal{V}} \geq \frac{1}{\mu_{\mathcal{G}}(\Phi, \Psi)} \left[ (1 - \varepsilon_U)(1 + \mu_{\mathcal{G}}(\Phi)) - \| U \|_{\mathcal{G}} \right]^{\dagger} \\
\times \left[ (1 - \varepsilon_V)(1 + \mu_{\mathcal{G}}(\Psi)) - \| \Psi \|_{\mathcal{G}} \right]^{\dagger}. \tag{14}
\]

Remark: [16] Th. 1] can be recovered from Theorem 5 by noting that \( \Phi \) and \( \Psi \) play the role of the dictionaries \( A \) and \( B \), respectively, as used in [15]. Then \( \Phi(u) = \Psi(v) \) becomes \( Au = Bv \) and [16] Th. 1] follows since \( \mu_{\mathcal{G}}(\Phi, \Psi) = \mu_m \), \( \mu_{\mathcal{G}}(\Phi) = \mu_u \), and \( \mu_{\mathcal{G}}(\Psi) = \mu_b \), with \( \mu_m, \mu_u, \) and \( \mu_b \) as defined in [16].

A. Shift-invariant spaces

We next show how Theorem 5 can be used to recover [10] Th. 1]. Consider the shift-invariant space
\[
\mathcal{G}_\phi \triangleq \left\{ z: z(t) = \sum_{i=1}^{n_1} v_k^{(i)} \phi_i(t - kT), v^{(i)} \in \ell_2, \forall i \right\}, \tag{15}
\]
with \( n_1 \) generators \( \phi_i \in L_2(\mathbb{R}) \) and \( \| \phi_i \|_2 = 1 \), for all \( i \). Set \( \mathcal{H}_1 \) to be the space of vector sequences
\[
v = \begin{pmatrix} v^{(1)} \\
\vdots \\
v^{(n_1)} \end{pmatrix}, \tag{16}
\]
with \( v^{(i)} \in \ell_2 \), for all \( i \). Define the operator \( \varphi_1: \ell_2 \to \mathcal{G}_\phi \) by
\[
\varphi_1 \left( v^{(i)} \right) \triangleq \sum_{k \in \mathbb{Z}} v_k^{(i)} \phi_i(t - kT), \tag{17}
\]
with adjoint \( \varphi_1^H: \mathcal{G}_\phi \to \ell_2 \) given by \( \varphi_1^H(z) = \left\{ (z)(\cdot), \phi_i(\cdot - \ell T) \right\}_{\ell_2} \). The sampling operator \( \Phi: \mathcal{H}_1 \to \mathcal{G}_\phi \) is then given by
\[
\Phi(v) \triangleq \sum_{i=1}^{n_1} \sum_{k \in \mathbb{Z}} v_k^{(i)} \phi_i(t - kT) = \sum_{i=1}^{n_1} \varphi_1 \left( v^{(i)} \right). \tag{18}
\]
A signal \( v \in \mathcal{G} \) is \( s \)-sparse if at most \( s \) of the sequences \( v^{(i)} \) in (18) are non-zero, i.e., if \( \| v \|_{\mathcal{G}, \phi} \leq s \), and in the terminology of [10], \( \| v \|_{\mathcal{G}, \phi} \) is the number of active generators.

Now let us consider a set of \( n_2 \) generators \( \theta_i \in L_2(\mathbb{R}) \) where \( \| \theta_i \|_2 = 1 \), for all \( i \), and the space
\[
\mathcal{G}_\theta \triangleq \left\{ z: z(t) = \sum_{i=1}^{n_1} v_k^{(i)} \theta_i(t - kT), v^{(i)} \in \ell_2, \forall i \right\}. \tag{19}
\]
Let \( \mathcal{H}_2 \) be the space of vector sequences, as in (16), but with \( n_1 \) replaced by \( n_2 \), and define the operators \( \varphi_2: \ell_2 \to \mathcal{G}_\theta \) and \( \Theta: \mathcal{H}_2 \to \mathcal{G}_\theta \) as in (17) and (18), respectively, with \( \phi_i \) replaced by \( \theta_i \). Suppose that \( z = \Phi(v) = \Theta(u) \). We now establish a limit on the sparsity of \( u \) and \( v \).

\[ \text{In this case, the sampling operator rather behaves like an interpolation operator as it maps a sequence to a continuous-time signal, but to maintain consistency with the rest of the paper we still refer to it as a sampling operator.} \]
Following [10] the generators will be assumed to satisfy:
$$\langle \phi_i (-kT), \phi_j (-lT) \rangle = \langle \theta_i (-kT), \theta_j (-lT) \rangle$$
\[
\begin{cases}
1 & \text{if } i = j \text{ and } k = l \\
0 & \text{otherwise}.
\end{cases}
\]

Then \( \| \varphi_i (v^{(i)}) \|_2 = \| v^{(i)} \|_2 \) for all \( i \), and for all \( v^{(i)} \in \ell_2 \), hence \( \omega_{\min} (\varphi_i) = 1 \), for all \( i \), and similarly \( \omega_{\min}(\varphi_{\ell}) = 1 \), for all \( \ell \). For \( i \neq j \) and \( v^{(i)} \in \ell_2 \), we have
\[
\begin{align*}
\| \varphi_i \varphi_j (v^{(j)}) \|_2^2 &= \left\| \sum_{k \in \mathbb{Z}} \langle \varphi_j (v^{(j)}), \varphi_i (-kT) \rangle \right\|^2 \\
&= \sum_{k \in \mathbb{Z}} \left\| \sum_{\ell \in \mathbb{Z}} 
\left( \sum_{k \in \mathbb{Z}} \langle v^{(j)}(k), \varphi_j (-\ell T), \varphi_i (-kT) \rangle \right)^2 \right. \\
&= \sum_{k \in \mathbb{Z}} \left\| \sum_{\ell \in \mathbb{Z}} \langle \varphi_j (-\ell T), \varphi_i (-kT) \rangle \right\|^2 = 0, \quad (19)
\end{align*}
\]
and similarly \( \| \varphi_i \varphi_j (v^{(j)}) \|_2^2 = 0 \), for all \( v^{(j)} \in \ell_2 \). Therefore, \( \mu_x (\Phi) = \max_{i \neq j} \omega_{\max}(\varphi_i \varphi_j) = 0 \) and similarly \( \mu_x (\Theta) = 0 \). This gives
\[
\mu_x (\Phi, \Theta) = \max_i \omega_{\max} (v_i^2 0) \mu_x (\Phi, \Theta) \geq 1,
\]
where we assume perfect concentration (since this is the case considered in [10]), i.e., \( \varepsilon_U = \varepsilon_Y = 0 \). We now show that (19) is the uncertainty relation in [10] Th. 1, which, in our notation, is given by (19) but with \( \mu_x (\Phi, \Theta) \) replaced by
\[
\mu (\Phi, \Theta) = \max_i \varepsilon_{\ell, r} (v_i^2 | x |)
\]
where
\[
R_{\varphi_i \varphi_j} (v_i^2) \overset{\Delta}{=} \{ \langle \varphi_i (\cdot) , \varphi_j (\cdot - kT) \rangle \} \in \mathbb{Z} (v_i^2).
\]
It therefore suffices to prove that \( \omega_{\max}(\varphi_i \varphi_j) = \varepsilon_{\ell, r} (v_i^2) \). For \( v^r \in \ell_2 \), we have
\[
\begin{align*}
\varphi^r \varphi_{\ell} (v^r) &= \left\{ \sum_{k \in \mathbb{Z}} v^r_k \langle \theta_{\ell} (\cdot - kT), \varphi_{\ell} (\cdot - mT) \rangle \right\} \\
&= \left\{ \sum_{m \in \mathbb{Z}} \Lambda_{m, k} \right\}
\end{align*}
\]
where \( \Lambda_{m, k} \overset{\Delta}{=} \langle \varphi_{\ell} (\cdot - kT), \theta_{\ell} (\cdot - mT) \rangle \). Then
\[
\omega_{\max}(\varphi^r \varphi_{\ell} = \sup_{v^r (\ell, r)} \| \varphi^r \varphi_{\ell} (v^r (\ell, r)) \|_2)
\]
\[
\begin{align*}
&= \sup_{v^r (\ell, r)} \| v^r (\ell, r) \|_2 \| \Lambda \|_{2 \to 2}, \quad \| \Lambda \|_{2 \to 2} = \| \Lambda \|_{2 \to 2}.
\end{align*}
\]
Since \( \Lambda \) is a doubly infinite Toeplitz matrix, its operator norm \( \| \Lambda \|_{2 \to 2} \) is given by the essential supremum of the Fourier transform of a row of \( \Lambda \) [23] p. 62]. We therefore have
\[
\omega_{\max}(\varphi^r \varphi_{\ell} (v_i^2) = \varepsilon_{\ell, r} (v_i^2), (19), \text{ which concludes the proof.}
\]

We finally note that our Theorem 5 also applies to nonorthogonal generator sets \( \{ \phi_i \} \) and \( \{ \theta_j \} \) with potentially different shift parameters, thereby extending the uncertainty relation in [10].
