Critical Population and Error Threshold on the Sharp Peak Landscape for the Wright–Fisher Model

By Raphaël Cerf

Université Paris Sud and IUF

We pursue the task of developing a finite population counterpart to Eigen’s model. We consider the classical Wright–Fisher model describing the evolution of a population of size $m$ of chromosomes of length $\ell$ over an alphabet of cardinality $\kappa$. The mutation probability per locus is $q$. The replication rate is $\sigma > 1$ for the master sequence and $1$ for the other sequences. We study the equilibrium distribution of the process in the regime where

$$\ell \to +\infty, \quad m \to +\infty, \quad q \to 0,$$

$$\ell q \to a \in ]0, +\infty[, \quad \frac{m}{\ell} \to \alpha \in [0, +\infty].$$

We obtain an equation $\alpha \psi(a) = \ln \kappa$ in the parameter space $(a, \alpha)$ separating the regime where the equilibrium population is totally random from the regime where a quasispecies is formed. We observe the existence of a critical population size necessary for a quasispecies to emerge, and we recover the finite population counterpart of the error threshold. The result is the twin brother of the corresponding result for the Moran model. The proof is more complex, and it relies on the Freidlin–Wentzell theory of random perturbations of dynamical systems.

1. Introduction. In 1971, Eigen studied a population of macromolecules, evolving under replication and mutation [7]. He considered the situation where one specific sequence, called the master sequence, replicates faster than the others. A fundamental discovery of Eigen is the existence of an error threshold. If the mutation rate exceeds a critical value, called the error threshold, then, at equilibrium, the population is completely random. If the mutation rate is below the error threshold, then, at equilibrium, the population contains a positive fraction of the master sequence and a cloud
of mutants which are quite close to the master sequence. This specific distribution of individuals is called a quasispecies. Since then, the notions of error threshold and quasispecies have been widely used to understand the evolution of populations in biology. However, biological populations are finite, and Eigen’s model cannot be directly applied in this context because it is formulated for an infinite population of macromolecules. A crucial task is therefore to reformulate and to understand the notions of error threshold and quasispecies in biological models describing the evolution of a finite population.

The Wright–Fisher model is one of the most studied models in mathematical population genetics. In this work, we apply to a basic Wright–Fisher model the ideas presented in [3] for the Moran model, thereby pursuing the task of developing a finite population counterpart to Eigen’s model. Numerous works have attacked this issue [1, 5, 11, 17, 21, 25]. Using different techniques, Saakian, Deem and Hu [24], Park, Muñoz and Deem [23], Musso [20] and Dixit, Srivastava and Vishnoi [6] considered finite population models which approximate Eigen’s model when the population size goes to infinity. These models are variants or generalizations of the classical Wright–Fisher model of population genetics. The problem is to understand how the error threshold phenomenon present in Eigen’s model in the infinite population limit shows up in the finite population model. We refer to the introduction of [3] for a detailed discussion of this question and the heuristics guiding our strategy. We consider here the classical Wright–Fisher model describing the evolution of a population of size \( m \) of chromosomes of length \( \ell \) over an alphabet of cardinality \( \kappa \). The mutation probability per locus is \( q \). The replication rate is \( \sigma > 1 \) for the master sequence and 1 for the other sequences. We study the equilibrium distribution of the process in the regime where

\[
\ell \to +\infty, \quad m \to +\infty, \quad q \to 0, \\
\ell q \to a \in \left]0, +\infty\right[, \quad \frac{m}{\ell} \to \alpha \in [0, +\infty].
\]

We obtain an equation \( \alpha \psi(a) = \ln \kappa \) in the parameter space \((a, \alpha)\) separating the regime where the equilibrium population is totally random from the regime where a quasispecies is formed. We observe the existence of a critical population size necessary for a quasispecies to emerge, and we recover the finite population counterpart of the error threshold. It is a classical fact that the Moran model and the Wright–Fisher model have similar dynamics. Indeed, the main result here is the twin brother of the main result of [3], the only difference being the equation of the critical curve. While we could compute exactly the critical curve for the Moran model, here the critical curve is defined through a variational problem depending on the parameter \( a \). Apart from this point, the scaling and the associated exponents are
the same in both cases. This confirms a conjecture of [3], and it sustains the hope that this kind of analysis is robust.

A potential application of the result concerns genetic algorithms. Indeed, the Wright–Fisher model is identical to the genetic algorithm without crossover. In her Ph.D. thesis [22], Ochoa investigated the role of the error threshold phenomenon for genetic algorithms, and she concluded that there exists a relationship between the optimal mutation rate and the error threshold. The result proved here provides a theoretical basis for some heuristics to control efficiently the genetic algorithms proposed in [2].

On the technical side, the Wright–Fisher model is much more difficult to handle than the Moran model. In the Moran model, the estimates of the selection drift relied on a birth and death model introduced by Nowak and Schuster [21]. In the Wright–Fisher model, the bounding processes are more complicated; they involve three dependent binomial laws. As the size of the population grows, their transition probabilities satisfy a large deviation principle, derived with the help of the classical Cramér theorem. In the set of the populations containing the master sequence, the process can be seen as the random perturbation of a discrete dynamical system. This discrete dynamical system is simply the sequence of the iterates of a rational map $F : [0, 1] \to [0, 1]$. Depending on the parameters, this map has either one stable fixed point or two fixed points, one stable and the other unstable. This opens the way to the application of the general scheme developed by Freidlin and Wentzell [10] to study the random perturbations of dynamical systems. Originally, Freidlin and Wentzell studied diffusion processes arising as Brownian perturbations of a differential equation. These processes are continuous time Markov processes with a continuous state space. However, their approach is robust, and it can be applied in other contexts. Kifer [14, 15] reworked this theory in the discrete time case. Unfortunately, our bounding processes do not fit the hypothesis of Kifer’s model, for the following two reasons. In Kifer’s model, the large deviation rate function of the transition probabilities is not allowed to be infinite, and the large deviation principle for the transition probabilities is assumed to be uniform with respect to the starting point. Certainly the general framework considered by Kifer could be adjusted to include our case, with the help of some relaxed hypothesis. Yet in our case, we have only two attractors, one unstable and one stable, and we need only two specific estimates from the general theory, which is concerned with a finite number of attractors of any type. In fact, the kind of estimates we need have been computed in two other works handling closely related models. In an unpublished work [4] (transmitted to me by courtesy of Gregory Morrow), Darden analyzed a Wright–Fisher model with two alleles and no mutation with the help of the Freidlin–Wentzell theory. What we have to do essentially is to obtain results analogous to Darden for the model with mutations. Morrow and Sawyer [19] considered a more
general model of Markov chains evolving in a convex subset of $\mathbb{R}^d$ around one stable attractor. Our bounding processes would fit this framework, were it for the uniform assumption on the variance of the transition probabilities. In our case, this condition is violated close to the unstable attractor 0. We can apply their results outside a neighborhood of 0, but this would lead to a messy construction. It appears that, in any case, if we try to apply the results of Kifer or of Morrow and Sawyer, we have to make a specific study of our process in the vicinity of the unstable fixed point 0. In the end, it seems that the most efficient presentation consists in deriving from scratch the required estimates, following the initial ideas of Freidlin and Wentzell. The techniques involved in the proof are classical and go back to the seminal work of Freidlin and Wentzell. However, there is an important simplifying feature in our case. Indeed, the bounding processes are monotone. This allows us to avoid uniform large deviation estimates and to provide substantially simpler proofs.

We describe the model in the next section, and we present the main result in Section 3. The rest of the paper is devoted to the proofs. The global strategy is identical to the case of the Moran model. The lumping is performed in Section 4. In Section 5, we build a coupling and we prove the monotonicity of the occupancy process. This allows us to define simple bounding processes in Section 6. Section 7, which analyzes the dynamics of the bounding processes, is much more complicated than for the Moran model. Section 8 presents the estimates in the neutral region. These estimates were derived in [3] for the Moran model, and they can be easily adapted to the Wright–Fisher model, so most of the proofs are omitted.

2. The Wright–Fisher model. Let $\mathcal{A}$ be a finite alphabet, and let $\kappa = \text{card} \mathcal{A}$ be its cardinality. Let $\ell \geq 1$ be an integer. We consider the space $\mathcal{A}^\ell$ of sequences of length $\ell$ over the alphabet $\mathcal{A}$. Elements of this space represent the chromosome of an haploid individual, or equivalently its genotype. In our model, all the genes have the same set of alleles, and each letter of the alphabet $\mathcal{A}$ is a possible allele. Typical examples are $\mathcal{A} = \{A, T, G, C\}$ to model standard DNA, or $\mathcal{A} = \{0, 1\}$ to deal with binary sequences. Generic elements of $\mathcal{A}^\ell$ will be denoted by the letters $u, v, w$. A population is an $m$-tuple of elements of $\mathcal{A}^\ell$. Generic populations will be denoted by the letters $x, y, z$. Thus a population $x$ is a vector

$$x = \begin{pmatrix} x(1) \\ \vdots \\ x(m) \end{pmatrix}$$

whose components are chromosomes. For $i \in \{1, \ldots, m\}$, we denote by

$$x(i, 1), \ldots, x(i, \ell)$$
the letters of the sequence $x(i)$. This way a population $x$ can be represented as an array

$$x = \begin{pmatrix} x(1,1) & \cdots & x(1,\ell) \\ \vdots & \ddots & \vdots \\ x(m,1) & \cdots & x(m,\ell) \end{pmatrix}$$

of size $m \times \ell$ of elements of $A$, the $i$th line being the $i$th chromosome. The evolution of the population is random and it is driven by two antagonistic forces: replication and mutation.

**Replication.** The replication favors the development of fit chromosomes. The fitness of a chromosome is encoded in a fitness function $A: A^\ell \rightarrow [0, +\infty]$. With the help of the fitness function $A$, we define a selection function $F: A^\ell \times (A^\ell)^m \rightarrow [0, 1]$ by setting

$$\forall u \in A^\ell, \forall x \in (A^\ell)^m \quad F(u, x) = \frac{A(u)}{A(x(1)) + \cdots + A(x(m))} \sum_{1 \leq i \leq m} 1_{x(i) = u}.$$  

The population $x$ being fixed, the values $F(u, x), \ u \in A^\ell$, define a probability distribution over $A^\ell$. The value $F(u, x)$ is the probability of choosing $u$ when sampling from the population $x$.

**Mutation.** The mutation mechanism is the same for all the loci, and mutations occur independently. We denote by $q \in [0, 1 - 1/\kappa]$ the probability that a mutation occurs at one particular locus. If a mutation occurs, then the letter is replaced randomly by another letter, chosen uniformly over the $\kappa - 1$ remaining letters. Mutations are rare, and the most likely outcome for a given letter is to stay unaltered; this is why we impose that $q \leq 1 - 1/\kappa$. We encode this mechanism in a mutation matrix

$$M(u, v), \quad u, v \in A^\ell,$$

where $M(u, v)$ is the probability that the chromosome $u$ is transformed by mutation into the chromosome $v$. The analytical formula for $M(u, v)$ is

$$M(u, v) = \prod_{j=1}^\ell \left( (1 - q)1_{u(j) = v(j)} + \frac{q}{\kappa - 1}1_{u(j) \neq v(j)} \right).$$

**Transition matrix.** We consider the classical Wright–Fisher model. In this model, generations do not overlap. The mechanism to build a new generation is divided in two steps. In the first step, $m$ chromosomes are sampled with replacement from the population. The sampling law is given by the selection
function. In the second step, each chromosome mutates according to the law specified by the mutation matrix. For \( n \geq 0 \), we denote by \( X_n \) the \( n \)th generation. The Wright–Fisher model is the Markov chain \( (X_n)_{n \in \mathbb{N}} \) on the space \((A^\ell)^m\) whose transition matrix is given by
\[
\forall n \in \mathbb{N}, \forall x, y \in (A^\ell)^m \quad P(X_{n+1} = y|X_n = x) = \prod_{1 \leq i \leq m} \left( \sum_{u \in A^\ell} F(u, x) M(u, y(i)) \right).
\]

3. Main results. We present the main results in this section.

Sharp peak landscape. We will consider only the sharp peak landscape defined as follows. We fix a specific sequence, denoted by \( w^* \), called the wild type or the master sequence. Let \( \sigma > 1 \) be a fixed real number. The fitness function \( A \) is given by
\[
\forall u \in A^\ell \quad A(u) = \begin{cases} 
1, & \text{if } u \neq w^*, \\
\sigma, & \text{if } u = w^*.
\end{cases}
\]

Density of the master sequence. We denote by \( N(x) \) the number of copies of the master sequence \( w^* \) present in the population \( x \):
\[
N(x) = \text{card}\{i : 1 \leq i \leq m, x(i) = w^*\}.
\]
We are interested in the expected density of the master sequence in the steady state distribution of the process, that is,
\[
\text{Master}(\sigma, \ell, m, q) = \lim_{n \to \infty} E\left( \frac{1}{m} N(X_n) \right),
\]
as well as the variance
\[
\text{Variance}(\sigma, \ell, m, q) = \lim_{n \to \infty} E\left( \left( \frac{1}{m} N(X_n) - \text{Master}(\sigma, \ell, m, q) \right)^2 \right).
\]
The ergodic theorem for Markov chains ensures that the above limits exist. We denote by \( I(p, t) \) the rate function governing the large deviations of the binomial law of parameter \( p \in [0, 1] \), given by
\[
\forall t \in [0, 1] \quad I(p, t) = t \ln \frac{t}{p} + (1 - t) \ln \frac{1 - t}{1 - p}.
\]
We define, for \( a \in ]0, +\infty[ \),
\[
\rho^*(a) = \begin{cases} 
\frac{\sigma e^{-a} - 1}{\sigma - 1}, & \text{if } \sigma e^{-a} > 1, \\
0, & \text{if } \sigma e^{-a} \leq 1,
\end{cases}
\]
\[ \psi(a) = \inf_{l \in \mathbb{N}} \left\{ \sum_{k=0}^{l-1} I \left( \frac{\sigma \rho_k}{(\sigma - 1)\rho_k + 1}, \gamma_k \right) + \gamma_k I \left( e^{-a}, \frac{\rho_k + 1}{\gamma_k} \right) : \rho_0 = \rho^*(a), \rho_l = 0, \rho_k, \gamma_k \in [0, 1] \text{ for } 0 \leq k < l \right\} . \]

Since \( I(p, 0) = -\ln(1 - p) \), we have
\[ \psi(a) \leq I \left( \frac{\sigma \rho^*(a)}{(\sigma - 1)\rho^*(a) + 1}, 0 \right) = \ln \frac{(\sigma - 1)\rho^*(a) + 1}{1 - \rho^*(a)} . \]

Thus the function \( \psi \) is finite on \( ]0, \ln \sigma[ \), and it vanishes on \( ]\ln \sigma, +\infty[ \). We will prove in Lemma 7.4 that \( \psi \) is positive on \( ]0, \ln \sigma[ \).

**Theorem 3.1.** We suppose that
\[ \ell \to +\infty, \quad m \to +\infty, \quad q \to 0, \]
in such a way that
\[ \ell q \to a \in ]0, +\infty[, \quad \frac{m}{\ell} \to \alpha \in [0, +\infty] . \]

We have the following dichotomy:
- If \( \alpha \psi(a) < \ln \kappa \), then \( \text{Master}(\sigma, \ell, m, q) \to 0 \).
- If \( \alpha \psi(a) > \ln \kappa \), then \( \text{Master}(\sigma, \ell, m, q) \to \rho^*(a) \).

In both cases, we have \( \text{Variance}(\sigma, \ell, m, q) \to 0 \).

The statement of the theorem holds also in the case where \( \alpha \) is null or infinite, but \( a \) must belong to \( ]0, +\infty[ \). This result is very similar to the result for the Moran model. Therefore all the comments made for the Moran model apply here as well. The main difference is that the function \( \psi(a) \) is more complicated. While we could obtain an explicit formula in the case of the Moran model, here the function \( \psi(a) \) is the solution of a complicated variational problem. The general structure of the proof is similar to the one for the Moran model. We use the lumping theorem to reduce the size of the state space. We couple the lumped processes with different initial conditions. The coupling for the occupancy process turns out to be monotone. We construct then a lower and an upper process. These processes behave like the original process in the neutral region and like a Wright–Fisher model with two alleles whenever the master sequence is present in the population. The dynamics of these models is analyzed with a specific implementation of the Freidlin–Wentzell theory. We compute estimates of the persistence time of the master sequence, as well as its equilibrium density. Although the results are similar to the case of the Moran model, this part
is much more technical in the case of the Wright–Fisher model. Indeed, in the case of the Moran model, we needed simply to estimate some explicit formula associated to the birth and death model introduced by Nowak and Schuster [21]. The approach used here to handle the Wright–Fisher model is quite robust, and it should work for other variants of the model. In the final section we analyze the discovery time of the master sequence. This part is similar to the case of the Moran model. It is even simpler, so most proofs are omitted.

4. Lumping. We denote by \( d_H \) the Hamming distance between two chromosomes

\[
\forall u, v \in A^\ell \quad d_H(u, v) = \text{card}\{j : 1 \leq j \leq \ell, u(j) \neq v(j)\}.
\]

We define a function \( H : A^\ell \rightarrow \{0, \ldots, \ell\} \) by setting

\[
\forall u \in A^\ell \quad H(u) = d_H(u, w^*).
\]

We define further a vector function \( \mathbb{H} : (A^\ell)^m \rightarrow \{0, \ldots, \ell\}^m \) by setting

\[
\forall x = \begin{pmatrix} x(1) \\ \vdots \\ x(m) \end{pmatrix} \in (A^\ell)^m \quad \mathbb{H}(x) = \begin{pmatrix} H(x(1)) \\ \vdots \\ H(x(m)) \end{pmatrix}.
\]

**Mutation.** We state some results on the mutation matrix that have been proved in [3]. The mutation matrix is lumpable with respect to the function \( H \). Let \( b, c \in \{0, \ldots, \ell\} \), and let \( u \in A^\ell \) such that \( H(u) = b \). The sum

\[
\sum_{w \in A^\ell \atop H(w) = c} M(u, w)
\]

does not depend on \( u \) in \( H^{-1}\{b\} \). It is a function of \( b \) and \( c \) only, which we denote by \( M_H(b, c) \). The coefficient \( M_H(b, c) \) is equal to

\[
\sum_{\substack{0 \leq k \leq \ell - b \\ 0 \leq l \leq b \\ k - l = c - b}} \binom{\ell - b}{k} \binom{b}{l} q^k (1 - q)^{\ell - b - k} \left( \frac{q}{\kappa - 1} \right)^l \left( 1 - \frac{q}{\kappa - 1} \right)^{b - l}.
\]

**Replication.** The fitness function \( A \) of the sharp peak landscape can be factorized through \( H \). If we define

\[
\forall b \in \{0, \ldots, \ell\} \quad A_H(b) = \begin{cases} \sigma, & \text{if } b = 0, \\ 1, & \text{if } b \geq 1, \end{cases}
\]

then we have

\[
\forall u \in A^\ell \quad A(u) = A_H(H(u)).
\]
Distance process. We define the distance process \((D_n)_{n \geq 0}\) by 

\[
\forall n \geq 0 \quad D_n = \mathbb{H}(X_n).
\]

As in [3], it can be checked that the Markov chain \((X_n)_{n \geq 0}\) is lumpable with respect to the partition of \((\mathcal{A}_l^m)\) induced by the map \(\mathbb{H}\), so that the distance process \((D_n)_{n \geq 0}\) is a genuine Markov chain. Its transition matrix \(p_H\) is given by

\[
\forall d, e \in \{0, \ldots, \ell\}^m
p_H(d, e) = \prod_{1 \leq i \leq m} \left( \sum_{1 \leq j \leq m} \frac{A_H(j) M_H(d(j), e(i))}{A_H(d(1)) + \cdots + A_H(d(m))} \right).
\]

Occupancy process. We denote by \(\mathcal{P}_{\ell+1}^m\) the set of the ordered partitions of the integer \(m\) in at most \(\ell + 1\) parts,

\[
\mathcal{P}_{\ell+1}^m = \{ (o(0), \ldots, o(\ell)) \in \mathbb{N}^{\ell+1} : o(0) + \cdots + o(\ell) = m \}.
\]

These partitions are interpreted as occupancy distributions. The partition \((o(0), \ldots, o(\ell))\) corresponds to a population in which \(o(l)\) chromosomes are at Hamming distance \(l\) from the master sequence, for any \(l \in \{0, \ldots, \ell\}\). Let \(O\) be the map which associates to each population \(x\) its occupancy distribution \(O(x) = (o(x,0), \ldots, o(x,\ell))\), defined by

\[
\forall l \in \{0, \ldots, \ell\} \quad o(x,l) = \text{card}\{ i : 1 \leq i \leq m, d_H(x(i), w^*) = l \}.
\]

For \(d \in \{0, \ldots, \ell\}^m\), we set

\[
o_H(d, l) = \text{card}\{ i : 1 \leq i \leq m, d(i) = l \},
\]

and we define a map \(O_H : \{0, \ldots, \ell\}^m \rightarrow \mathcal{P}_{\ell+1}^m\) by setting

\[
O_H(d) = (o_H(d,0), \ldots, o_H(d,\ell)).
\]

We define the occupancy process \((O_n)_{n \geq 0}\) by setting

\[
\forall n \geq 0 \quad O_n = O(X_n) = O_H(D_n).
\]

As in [3], it can be checked that the Markov chain \((D_n)_{n \geq 0}\) is lumpable with respect to the partition of \(\{0, \ldots, \ell\}^m\) induced by the map \(O_H\), so that the occupancy process \((O_n)_{n \geq 0}\) is a genuine Markov chain. Its transition matrix \(p_O\) is given by

\[
\forall o, o' \in \mathcal{P}_{\ell+1}^m \quad p_O(o, o') = \prod_{0 \leq h \leq \ell} \left( \frac{\sum_{k \in \{0, \ldots, \ell\}} o(k) A_H(k) M_H(k, h)}{\sum_{0 \leq h \leq \ell} o(h) A_H(h)} \right)^{o'(h)}.
\]
5. Monotonicity. A crucial property for comparing the Wright–Fisher model with other processes is monotonicity. We will realize a coupling of the lumped Wright–Fisher processes with different initial conditions, and we will deduce the monotonicity from the coupling construction. All the processes will be built on a single large probability space. We consider a probability space $(\Omega, \mathcal{F}, P)$ containing the following collection of independent random variables, all of them following the uniform law on the interval $[0, 1]$: 

$$U_{n}^{i,j}, \quad n \geq 1, \quad 1 \leq i \leq m, \quad 1 \leq j \leq \ell, 
S_{n}^{i}, \quad n \geq 1, \quad 1 \leq i \leq m.$$ 

5.1. Coupling of the lumped processes. We build here a coupling of the lumped processes. We set 

$$\forall n \geq 1 \quad R_{n} = \begin{pmatrix}
S_{n}^{1,1}, & U_{n}^{1,1}, & \cdots, & U_{n}^{1,\ell} \\
\vdots & \vdots & \ddots & \vdots \\
S_{n}^{m,1}, & U_{n}^{m,1}, & \cdots, & U_{n}^{m,\ell}
\end{pmatrix}.$$ 

The matrix $R_{n}$ is the random input which is used to perform the $n$th step of the Markov chains. We denote by $\mathcal{R}$ the set of the matrices of size $m \times (\ell + 1)$ with coefficients in $[0, 1]$. The sequence $(R_{n})_{n \geq 1}$ is a sequence of independent identically distributed random matrices with values in $\mathcal{R}$.

Mutation. We define a map 

$$\mathcal{M}_{H} : \{0, \ldots, \ell\} \times [0, 1]^{\ell} \to \{0, \ldots, \ell\}$$

in order to couple the mutation mechanism starting with different chromosomes. Let $b \in \{0, \ldots, \ell\}$, and let $u_{1}, \ldots, u_{\ell} \in [0, 1]^{\ell}$. The map $\mathcal{M}_{H}$ is defined by setting 

$$\mathcal{M}_{H}(b, u_{1}, \ldots, u_{\ell}) = b - \sum_{k=1}^{b} 1_{u_{k} < q/(\kappa-1)} + \sum_{k=b+1}^{\ell} 1_{u_{k} > 1-q}.$$ 

The map $\mathcal{M}_{H}$ is built in such a way that, if $U_{1}, \ldots, U_{\ell}$ are random variables with uniform law on the interval $[0, 1]$, all being independent, then for any $b \in \{0, \ldots, \ell\}$, the law of $\mathcal{M}_{H}(b, U_{1}, \ldots, U_{\ell})$ is given by the line of the mutation matrix $M_{H}$ associated to $b$, that is, 

$$\forall c \in \{0, \ldots, \ell\} \quad P(\mathcal{M}_{H}(b, U_{1}, \ldots, U_{\ell}) = c) = M_{H}(b, c).$$

Selection for the distance process. We realize the replication mechanism with the help of a selection map 

$$S_{H} : \{0, \ldots, \ell\}^{m} \times [0, 1] \to \{1, \ldots, m\}.$$
Let $d \in \{0, \ldots, \ell\}^m$, and let $s \in [0, 1]$. We define $S_H(d, s) = i$ where $i$ is the unique index in $\{1, \ldots, m\}$ satisfying
\[
\frac{A_H(d(1)) + \cdots + A_H(d(i-1))}{A_H(d(1)) + \cdots + A_H(d(m))} \leq s < \frac{A_H(d(1)) + \cdots + A_H(d(i))}{A_H(d(1)) + \cdots + A_H(d(m))}.
\]
The map $S_H$ is built in such a way that, if $S$ is a random variable with uniform law on the interval $[0, 1]$, then for any $d \in \{0, \ldots, \ell\}^m$, the law of $S_H(d, S)$ is given by
\[
\forall i \in \{1, \ldots, m\} \quad P(S_H(d, S) = i) = \frac{A_H(d(i))}{A_H(d(1)) + \cdots + A_H(d(m))}.
\]

**Coupling for the distance process.** We build a deterministic map
\[
\Psi_H : \{0, \ldots, \ell\}^m \times R \to \{0, \ldots, \ell\}^m
\]
in order to realize the coupling between distance processes with various initial conditions. The coupling map $\Psi_H$ is defined by
\[
\forall r \in R, \forall d \in \{0, \ldots, \ell\}^m \quad \Psi_H(d, r) = \begin{pmatrix}
M_H(d(S_H(d, r(1, 1))), r(1, 2), \ldots, r(1, \ell + 1)) \\
\vdots \\
M_H(d(S_H(d, r(m, 1))), r(m, 2), \ldots, r(m, \ell + 1))
\end{pmatrix}.
\]
The coupling is then built in a standard way with the help of the i.i.d. sequence $(R_n)_{n \geq 1}$ and the map $\Psi_H$. Let $d \in \{0, \ldots, \ell\}^m$ be the starting point of the process. We build the distance process $(D_n)_{n \geq 0}$ by setting $D_0 = d$ and
\[
\forall n \geq 1 \quad D_n = \Psi_H(D_{n-1}, R_n).
\]
A routine check shows that the process $(D_n)_{n \geq 0}$ is a Markov chain starting from $d$ with the adequate transition matrix. This way we have coupled the distance processes with various initial conditions.

**Selection for the occupancy process.** We realize the replication mechanism with the help of a selection map
\[
S_O : P_{\ell+1}^m \times [0, 1] \to \{0, \ldots, \ell\}.
\]
Let $o \in P_{\ell+1}^m$, and let $s \in [0, 1]$. We define $S_O(o, s) = l$ where $l$ is the unique index in $\{0, \ldots, \ell\}$ satisfying
\[
\frac{o(0)A_H(0) + \cdots + o(l-1)A_H(l-1)}{o(0)A_H(0) + \cdots + o(\ell)A_H(\ell)} \leq s < \frac{o(0)A_H(0) + \cdots + o(l)A_H(l)}{o(0)A_H(0) + \cdots + o(\ell)A_H(\ell)}.
\]
The map $S_O$ is built in such a way that, if $S$ is a random variable with uniform law on the interval $[0, 1]$, then for any $o \in P_{\ell+1}^m$, the law of $S_O(o, S)$ is given by
\[
\forall l \in \{0, \ldots, \ell\} \quad P(S_O(o, S) = l) = \frac{o(l)A_H(l)}{o(0)A_H(0) + \cdots + o(\ell)A_H(\ell)}.
\]
Coupling for the occupancy process. We build a deterministic map

$$\Psi : \mathcal{P}_{\ell+1}^m \times \mathcal{R} \to \mathcal{P}_{\ell+1}^m$$

in order to realize the coupling between occupancy processes with various initial conditions. The coupling map $\Psi$ is defined by

$$\Psi(o,r) = \mathcal{O}_H \left( \begin{array}{c}
M_H(S_O(o,r(1,1)), r(1,2), \ldots, r(1,\ell+1)) \\
\vdots \\
M_H(S_O(o,r(m,1)), r(m,2), \ldots, r(m,\ell+1))
\end{array} \right).$$

Let $o \in \mathcal{P}_{\ell+1}^m$ be the starting point of the process. We build the occupancy process $(O_n)_{n \geq 0}$ by setting $O_0 = o$ and

$$\forall n \geq 1 \quad O_n = \Psi(O_{n-1}, R_n).$$

A routine check shows that the process $(O_n)_{n \geq 0}$ is a Markov chain starting from $o$ with the adequate transition matrix. This way we have coupled the occupancy processes with various initial conditions.

5.2. Monotonicity of the model. We first recall some standard definitions concerning monotonicity and coupling for stochastic processes. A classical reference is Liggett’s book [16], especially for applications to particle systems. In the next two definitions, we consider a discrete time Markov chain $(X_n)_{n \geq 0}$ with values in a space $\mathcal{E}$. We suppose that the state space $\mathcal{E}$ is finite and that it is equipped with a partial order $\leq$. A function $f : \mathcal{E} \to \mathbb{R}$ is nondecreasing if

$$\forall x, y \in \mathcal{E} \quad x \leq y \quad \Rightarrow \quad f(x) \leq f(y).$$

**Definition 5.1.** The Markov chain $(X_n)_{n \geq 0}$ is said to be monotone if, for any nondecreasing function $f$, the function

$$x \in \mathcal{E} \mapsto E(f(X_n) | X_0 = x)$$

is nondecreasing.

A natural way to prove monotonicity is to construct an adequate coupling.

**Definition 5.2.** A coupling for the Markov chain $(X_n)_{n \geq 0}$ is a family of processes $(X^x_n)_{n \geq 0}$ indexed by $x \in \mathcal{E}$, which are all defined on the same probability space, and such that, for $x \in \mathcal{E}$, the process $(X^x_n)_{n \geq 0}$ is the Markov chain $(X_n)_{n \geq 0}$ starting from $X_0 = x$. The coupling is said to be monotone if

$$\forall x, y \in \mathcal{E} \quad x \leq y \quad \Rightarrow \quad \forall n \geq 1 \quad X^x_n \leq X^y_n.$$
If there exists a monotone coupling, then the Markov chain is monotone. We try next to apply these definitions to our model. The space \( \{0, \ldots, \ell\}^m \) is naturally endowed with a partial order
\[
d \leq e \iff \forall i \in \{1, \ldots, m\} \quad d(i) \leq e(i).
\]
The map \( M_H \) is nondecreasing with respect to the Hamming class, that is,
\[
\forall b, c \in \{0, \ldots, \ell\}, \forall u_1, \ldots, u_\ell \in [0, 1]\quad b \leq c \Rightarrow M_H(b, u_1, \ldots, u_\ell) \leq M_H(c, u_1, \ldots, u_\ell);
\]
see [3] for a detailed proof. In the neutral case \( \sigma = 1 \), the map \( S_H \) does not depend on the population, in fact,
\[
\forall d \in \{0, \ldots, \ell\}^m, \forall s \in [0, 1] \quad S_H(d, s) = \lfloor ms \rfloor.
\]
As a consequence, we have
\[
\forall d, e \in \{0, \ldots, \ell\}^m, \forall s \in [0, 1] \quad d \leq e \Rightarrow d(S_H(d, s)) \leq e(S_H(e, s)).
\]

**Lemma 5.3.** In the neutral case \( \sigma = 1 \), the map \( \Psi_H \) is nondecreasing with respect to the distances, that is,
\[
\forall d, e \in \{0, \ldots, \ell\}^m, \forall r \in \mathcal{R} \quad d \leq e \Rightarrow \Psi_H(d, r) \leq \Psi_H(e, r).
\]

**Proof.** Let \( r \in \mathcal{R} \), and let \( d, e \in \{0, \ldots, \ell\}^m, d \leq e \). Let \( i \in \{1, \ldots, m\} \).
Since
\[
S_H(d, r(i, 1)) = S_H(e, r(i, 1)) = \lfloor mr(i, 1) \rfloor,
\]
we have
\[
d(S_H(d, r(i, 1))) \leq e(S_H(e, r(i, 1))).
\]
This inequality and the monotonicity of the map \( M_H \) imply that
\[
M_H(d(S_H(d, r(i, 1))), r(i, 2), \ldots, r(i, \ell + 1)) \leq M_H(e(S_H(e, r(i, 1))), r(i, 2), \ldots, r(i, \ell + 1)).
\]
Therefore \( \Psi_H(d, r) \leq \Psi_H(e, r) \) as requested. \( \square \)

**Corollary 5.4.** In the neutral case \( \sigma = 1 \), the distance process \( (D_n)_{n \geq 0} \) is monotone.

Unfortunately, the map \( \Psi_H \) is not monotone for \( \sigma > 1 \). Indeed, suppose that
\[
\kappa = 3, \quad \sigma = 2, \quad m = 3, \quad \ell \geq 2,
\]
\[
\frac{2}{3} < s_1 < \frac{3}{4}, \quad \frac{2}{3} < s_2 < 1, \quad \frac{3}{4} < s_3 < 1,
\]
\[
\forall i \in \{1, 2, 3\}, \forall j \in \{1, \ldots, \ell\} \quad u_{i,j} \in \left[\frac{q}{3}, 1 - q\right].
\]
Recall that

\[ r = \begin{pmatrix} s_1, u_{1,1}, \ldots, u_{1,\ell} \\ s_2, u_{2,1}, \ldots, u_{2,\ell} \\ s_3, u_{3,1}, \ldots, u_{3,\ell} \end{pmatrix}. \]

We have then

\[ \Psi_H \begin{pmatrix} 0 \\ 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 2 \\ 1 \\ 1 \end{pmatrix}, \quad \Psi_H \begin{pmatrix} 1 \\ 2 \\ 1 \end{pmatrix} = \begin{pmatrix} 1 \\ 1 \\ 1 \end{pmatrix}. \]

This creates a serious complication. To get around this problem, we lump further the distance process in order to build the occupancy process. It turns out that the occupancy process is monotone even in the nonneutral case. We define an order \( \preceq \) on \( P_{m, \ell+1} \) as follows. Let \( o = (o(0), \ldots, o(\ell)) \) and \( o' = (o'(0), \ldots, o'(\ell)) \) belong to \( P_{m, \ell+1} \). We say that \( o \) is smaller than or equal to \( o' \), which we denote by \( o \preceq o' \), if

\[ \forall l \leq \ell \quad o(0) + \cdots + o(l) \leq o'(0) + \cdots + o'(l). \]

As shown in [3], the map \( S_O \) is nonincreasing with respect to the occupancy distribution, that is,

\[ \forall o, o' \in P_{m, \ell+1}, \forall s \in [0, 1] \quad o \preceq o' \Rightarrow S_O(o, s) \geq S_O(o', s). \]

**Lemma 5.5.** The map \( \Psi_O \) is nondecreasing with respect to the occupancy distribution, that is,

\[ \forall o, o' \in P_{m, \ell+1}, \forall r \in \mathcal{R} \quad o \preceq o' \Rightarrow \Psi_O(o, r) \leq \Psi_O(o', r). \]

**Proof.** Let \( r \in \mathcal{R} \), and let \( o, o' \in P_{m, \ell+1} \) be such that \( o \preceq o' \). Using the monotonicity of the map \( S_O \), we have

\[ \forall i \in \{1, \ldots, m\} \quad S_O(o, r(i, 1)) \geq S_O(o', r(i, 1)). \]

This inequality and the monotonicity of the map \( M_H \) imply that

\[ \forall i \in \{1, \ldots, m\} \quad M_H(S_O(o, r(i, 1)), r(i, 2), \ldots, r(i, \ell + 1)) \geq M_H(S_O(o', r(i, 1)), r(i, 2), \ldots, r(i, \ell + 1)). \]

Therefore \( \Psi_O(o, r) \leq \Psi_O(o', r) \) as requested. \( \square \)

**Corollary 5.6.** The occupancy process \((O_n)_{n \geq 0}\) is monotone.
5.3. The FKG inequality. We consider the product space \( \{0, \ldots, \ell\}^m \) equipped with the natural product order
\[
d \leq e \iff \forall i \in \{1, \ldots, m\} \quad d(i) \leq e(i).
\]

**Definition 5.7.** A probability measure \( \mu \) on \( \{0, \ldots, \ell\}^m \) is said to have positive correlations if for any functions \( f, g: \{0, \ldots, \ell\}^m \rightarrow \mathbb{R} \) which are non-decreasing, we have
\[
\sum_{d \in \{0, \ldots, \ell\}^m} f(d) g(d) \mu(d) \geq \left( \sum_{d \in \{0, \ldots, \ell\}^m} f(d) \mu(d) \right) \left( \sum_{d \in \{0, \ldots, \ell\}^m} g(d) \mu(d) \right).
\]

The Harris inequality, or the FKG inequality in this context, says that any product probability measure on \( \{0, \ldots, \ell\}^m \) has positive correlations. The FKG inequality is in fact true for any product probability measure on a product of the interval \([0, 1]\); see Section 2.2 of Grimmett’s book [12]. As far as correlations are concerned, there is not much to do with the original Wright–Fisher model because its state space is not partially ordered. So we examine the distance process.

**Proposition 5.8.** Suppose that we are in the neutral case \( \sigma = 1 \). If the law of \( D_0 \) has positive correlations, then for any \( n \geq 0 \), the law of \( D_n \) has positive correlations.

**Proof.** The Wright–Fisher model \((X_n)_{n \geq 0}\) can be seen as a probabilistic cellular automaton. Indeed, given the population \( X_n = x \) at time \( n \), the individuals \((X_{n+1}(i), 1 \leq i \leq m)\) of the population at time \( n + 1 \) are independent. This still holds for the distance process. By Corollary 5.4, the neutral distance process \((D_n)_{n \geq 0}\) is monotone. Monotone probabilistic cellular automata preserve the FKG inequality. This is explained in detail by Mezić [18], and it was first observed by Harris [13] at the very end of his article on continuous time processes. Because the argument is very short, we reproduce it here. Suppose that the initial law \( \mu \) of \( D_0 \) has positive correlations. Let \( f, g: \{0, \ldots, \ell\}^m \rightarrow \mathbb{R} \) be two nondecreasing functions. For any \( d \in \{0, \ldots, \ell\}^m \), the conditional law of \( D_1 \) knowing that \( D_0 = d \) is a product measure on \( \{0, \ldots, \ell\}^m \), thus it satisfies the FKG inequality, whence
\[
\forall d \in \{0, \ldots, \ell\}^m \quad E(f(D_1)g(D_1)|D_0 = d) \geq E(f(D_1)|D_0 = d)E(g(D_1)|D_0 = d).
\]
We integrate the inequality with respect to the initial law \( \mu \):
\[
\sum_{d \in \{0, \ldots, \ell\}^m} E(f(D_1)g(D_1)|D_0 = d)\mu(d) \geq \sum_{d \in \{0, \ldots, \ell\}^m} E(f(D_1)|D_0 = d)E(g(D_1)|D_0 = d)\mu(d).
\]
Since \((D_n)_{n \geq 0}\) is monotone, the maps
\[
d \in \{0, \ldots, \ell\}^m \mapsto E(f(D_1) | D_0 = d),
\]
\[
d \in \{0, \ldots, \ell\}^m \mapsto E(g(D_1) | D_0 = d),
\]
are nondecreasing. By hypothesis, the initial law \(\mu\) has positive correlations, therefore
\[
\sum_{d \in \{0, \ldots, \ell\}^m} E(f(D_1) | D_0 = d) E(g(D_1) | D_0 = d) \mu(d)
\geq \left( \sum_{d \in \{0, \ldots, \ell\}^m} E(f(D_1) | D_0 = d) \mu(d) \right) \left( \sum_{d \in \{0, \ldots, \ell\}^m} E(g(D_1) | D_0 = d) \mu(d) \right).
\]
The two above inequalities imply that the law of \(D_1\) has positive correlations. We conclude by iterating the argument. \(\square\)

6. Stochastic bounds. In this section, we take advantage of the monotonicity of the map \(\Psi_O\) to compare the process \((O_n)_{n \geq 0}\) with simpler processes.

6.1. Lower and upper processes. We shall build a lower process \((O^\ell_n)_{n \geq 0}\) and an upper process \((O^1_n)_{n \geq 0}\) satisfying
\[
\forall n \geq 0 \quad O^\ell_n \preceq O_n \preceq O^1_n.
\]
Loosely speaking, the upper process evolves as follows. As long as there is no master sequence present in the population, the process \((O^1_n)_{n \geq 0}\) evolves exactly as the initial process \((O_n)_{n \geq 0}\). When the first master sequence appears, all the other chromosomes are set in the Hamming class 1; that is, the process jumps to the state \((1, m - 1, 0, \ldots, 0)\). As long as the master sequence is present, the mutations on nonmaster sequences leading to nonmaster sequences are suppressed, and any mutation of a master sequence leads to a chromosome in the first Hamming class. The dynamics of the lower process is similar, except that the chromosomes distinct from the master sequence are sent to the last Hamming class \(\ell\) instead of the first one. We shall next construct precisely these dynamics. We define two maps \(\pi_\ell, \pi_1 : \mathcal{P}_{\ell+1} \to \mathcal{P}_{\ell+1}\) by setting
\[
\forall o \in \mathcal{P}_{\ell+1} \quad \pi_\ell(o) = (o(0), 0, \ldots, 0, m - o(0)),
\]
\[
\pi_1(o) = (o(0), m - o(0), 0, \ldots, 0).
\]
Obviously,
\[
\forall o \in \mathcal{P}_{\ell+1} \quad \pi_\ell(o) \preceq o \preceq \pi_1(o).
\]
We denote by $W^*$ the set of the occupancy distributions containing the master sequence, that is,

$$W^* = \{o \in P_{\ell+1}^m : o(0) \geq 1\}$$

and by $\mathcal{N}$ the set of the occupancy distributions which do not contain the master sequence, that is,

$$\mathcal{N} = \{o \in P_{\ell+1}^m : o(0) = 0\}.$$

Let $\Psi_O$ be the coupling map defined in Section 5.1. We define a lower map $\Psi_O^\ell$ by setting, for $o \in P_{\ell+1}^m$ and $r \in R$,

$$\Psi_O^\ell(o,r) = \begin{cases} 
\Psi_O(o,r), & \text{if } o \in \mathcal{N} \text{ and } \Psi_O(o,r) \notin W^*, \\
\pi_1(\Psi_O(o,r)), & \text{if } o \in \mathcal{N} \text{ and } \Psi_O(o,r) \in W^*, \\
\pi_1(\Psi_O(\pi_1(o),r)), & \text{if } o \in W^*.
\end{cases}$$

Similarly, we define an upper map $\Psi_O^1$ by setting, for $o \in P_{\ell+1}^m$ and $r \in R$,

$$\Psi_O^1(o,r) = \begin{cases} 
\Psi_O(o,r), & \text{if } o \in \mathcal{N} \text{ and } \Psi_O(o,r) \notin W^*, \\
\pi_1(\Psi_O(o,r)), & \text{if } o \in \mathcal{N} \text{ and } \Psi_O(o,r) \in W^*, \\
\pi_1(\Psi_O(\pi_1(o),r)), & \text{if } o \in W^*.
\end{cases}$$

A direct application of Lemma 5.5 yields that the map $\Psi_O^\ell$ is below the map $\Psi_O$ and the map $\Psi_O^1$ is above the map $\Psi_O$ in the following sense:

$$\forall r \in R, \forall o \in P_{\ell+1}^m, \quad \Psi_O^\ell(o,r) \preceq \Psi_O(o,r) \preceq \Psi_O^1(o,r).$$

We define a lower process $(O_n^\ell)_{n \geq 0}$ and an upper process $(O_n^1)_{n \geq 0}$ with the help of the i.i.d. sequence $(R_n)_{n \geq 1}$ and the maps $\Psi_O^\ell$, $\Psi_O^1$ as follows. Let $o \in P_{\ell+1}^m$ be the starting point of the process. We set $O_0^\ell = O_0^1 = o$ and

$$\forall n \geq 1, \quad O_n^\ell = \Psi_O^\ell(O_{n-1}^\ell, R_n), \quad O_n^1 = \Psi_O^1(O_{n-1}^1, R_n).$$

**Proposition 6.1.** Suppose that the three processes $(O_n^\ell)_{n \geq 0}$, $(O_n)_{n \geq 0}$, $(O_n^1)_{n \geq 0}$, start from the same occupancy distribution $o$. We have

$$\forall n \geq 0, \quad O_n^\ell \preceq O_n \preceq O_n^1.$$ 

The proof is similar to the proof of Proposition 8.1 in [3].

**6.2. Dynamics of the bounding processes.** We study next the dynamics of the processes $(O_n^\ell)_{n \geq 0}$ and $(O_n^1)_{n \geq 0}$ in $W^*$. The computations are the same for both processes. Throughout the section, we fix $\theta$ to be either 1 or $\ell$, and we denote by $(O_n^\theta)_{n \geq 0}$ the corresponding process. For the process $(O_n^\theta)_{n \geq 0}$, the states

$$T^\theta = \{o \in P_{\ell+1}^m : o(0) \geq 1 \text{ and } o(0) + o(\theta) < m\}$$

we refer to as the critical population and error threshold.
are transient, while the populations in $\mathcal{N} \cup (\mathcal{W}^* \setminus T^\theta)$ form a recurrent class. Let us look at the transition mechanism of the process restricted to $\mathcal{W}^* \setminus T^\theta$. Since

$$\mathcal{W}^* \setminus T^\theta = \{ o \in \mathcal{P}_\ell^m : o(0) \geq 1 \text{ and } o(0) + o(\theta) = m \},$$

we see that a state of $\mathcal{W}^* \setminus T^\theta$ is completely determined by the first occupancy number, which is equal to the number of copies of the master sequence present in the population. From the previous observations, we conclude that, whenever $(O^\theta_n)_{n \geq 0}$ starts in $\mathcal{W}^* \setminus T^\theta$, the dynamics of the number of master sequences $(O^\theta_n(0))_{n \geq 0}$ is Markovian until the time of exit from $\mathcal{W}^* \setminus T^\theta$. We denote by $(Z^\theta_n)_{n \geq 0}$ a Markov chain on $\{0, \ldots, m\}$ with the following transition probabilities: for $h \in \{1, \ldots, m\}$ and $k \in \{0, \ldots, m\}$,

$$\forall n \geq 0 \quad P(Z^\theta_{n+1} = k | Z^\theta_n = h) = P(O^\theta_{n+1}(0) = k | O^\theta_n(0) = h),$$

and for $h = 0$ and $k \in \{0, \ldots, m\}$,

$$\forall n \geq 0 \quad P(Z^\theta_{n+1} = k | Z^\theta_n = 0) = \binom{m}{k} \hat{M}(\theta, 0)^k (1 - \hat{M}(\theta, 0))^{m-k}.$$

Let us denote by $p^\theta(h, k)$ the above transition probability, and let us compute its value. We use the definition of the transition mechanism of $(O^\theta_n)_{n \geq 0}$ to get

$$p^\theta(h, k) = \sum_{i \in \{0, \ldots, m\}} \sum_{j=0}^{i} p^\theta(h, i, j, k)$$

where $p^\theta(h, i, j, k)$ is given by

$$p^\theta(h, i, j, k) = P\left( \begin{array}{c} i \text{ master sequences are selected,} \\ j \text{ master sequences do not mutate,} \\ k - j \text{ nonmaster sequences mutate into a master sequence} \end{array} \bigg| Z^\theta_n = h \right)$$

$$= \binom{m}{i} \frac{(\sigma h)^i (m-h)^{m-i}}{(m-1)^{h+m}} \binom{i}{j} M_H(0,0)^j (1 - M_H(0,0))^{i-j}$$

$$\times \binom{m-i}{k-j} M_H(\theta,0)^{k-j} (1 - M_H(\theta,0))^{m-i-k+j}.$$

The Markov chain $(Z^\theta_n)_{n \geq 0}$ corresponds to the evolution of the number of master sequences in a Wright–Fisher model with two types, the master type having fitness $\sigma$ and the other type having fitness $1$, and with the following mutation matrix between the two types:

- $P(\text{the master type mutates into the nonmaster type}) = 1 - M_H(0,0)$,
- $P(\text{the nonmaster type mutates into the master type}) = M_H(\theta,0)$. 

We can also realize the Markov chain \((Z_\theta^n)_{n\geq 0}\) on our common probability space. We define two maps \(\Xi^\ell, \Xi^1: \{0, \ldots, m\} \to \mathcal{P}_{\ell+1}^m\) by setting
\[
\Xi^\ell(i) = (i, 0, \ldots, 0, m - i), \quad \Xi^1(i) = (i, m - i, 0, \ldots, 0).
\]
Let \(i \in \{0, \ldots, m\}\) be the starting point of the process. We set \(Z_\theta^0 = i\) and
\[
\forall n \geq 1 \quad Z_\theta^n = \Psi^\ell_\theta(\Xi^\ell(Z_\theta^{n-1}), R_n)(0).
\]
This construction yields a Markov chain \((Z_\theta^n)_{n\geq 0}\) starting from \(i\) with the adequate transition matrix. Moreover the maps \(\Xi^\ell, \Xi^1\) are nondecreasing. By Lemma 5.5, the map \(\Psi^\ell_\theta\) is also nondecreasing with respect to the occupancy distribution. We conclude that the above coupling is monotone, and the Markov chain \((Z_\theta^n)_{n\geq 0}\) is monotone.

6.3. Invariant probability measures. Our goal is to estimate the law \(\nu\) of the fraction of the master sequence in the population at equilibrium. The probability measure \(\nu\) is the probability measure on the interval \([0, 1]\) satisfying the following identities. For any function \(f: [0, 1] \to \mathbb{R}\),
\[
\int_{[0,1]} f \, d\nu = \lim_{n \to \infty} E \left( f \left( \frac{1}{m} N(X_n) \right) \right) = \sum_{x \in (A^\ell)^m} f \left( \frac{1}{m} N(x) \right) \mu(x),
\]
where \(\mu\) is the invariant probability measure of the Markov chain \((X_n)_{n\geq 0}\). In fact, the probability measure \(\nu\) is the image of \(\mu\) through the map
\[
x \in (A^\ell)^m \mapsto \frac{1}{m} N(x) \in [0, 1].
\]
We denote by \(\mu^\ell_\theta, \mu_\theta, \mu^1_\theta\) the invariant probability measures of the Markov chains \((O^\ell_n)_{n\geq 0}, (O_n)_{n\geq 0}, (O^1_n)_{n\geq 0}\). The probability \(\nu\) is also the image of \(\mu_\theta\) through the map
\[
o \in \mathcal{P}_{\ell+1}^m \mapsto \frac{1}{m} o(0) \in [0, 1].
\]
Thus, for any function \(f: [0, 1] \to \mathbb{R}\),
\[
\int_{[0,1]} f \, d\nu = \sum_{o \in \mathcal{P}_{\ell+1}^m} f \left( \frac{o(0)}{m} \right) \mu_\theta(o) = \lim_{n \to \infty} E \left( f \left( \frac{1}{m} O_n(0) \right) \right).
\]
We fix now a nondecreasing function \(f: [0, 1] \to \mathbb{R}\) such that \(f(0) = 0\). Proposition 6.1 yields the inequalities
\[
\forall n \geq 0 \quad f \left( \frac{1}{m} O^\ell_n(0) \right) \leq f \left( \frac{1}{m} O_n(0) \right) \leq f \left( \frac{1}{m} O^1_n(0) \right).
\]
Taking the expectation and sending $n$ to $\infty$, we get
\[ \sum_{o \in P_{\ell+1}^m} f\left(\frac{o(0)}{m}\right) \mu_O(o) \leq \int_{[0,1]} f \, d\nu \leq \sum_{o \in P_{\ell+1}^m} f\left(\frac{o(0)}{m}\right) \mu^1_O(o). \]

We seek next estimates on the above sums. The strategy is the same for the lower and the upper sum. Thus we fix $\theta$ to be either 1 or $\ell$, and we study the invariant probability measure $\mu^\theta_O$. For the Markov chain $(O^\theta_n)_{n \geq 0}$, the states of $T^\theta$ are transient, while the populations in $N \cup (W^* \setminus T^\theta)$ form a recurrent class. Let $o^\theta_{\text{exit}}$ be the occupancy distribution having $m$ chromosomes in the Hamming class $\theta$,
\[ \forall l \in \{0, \ldots, \ell\} \quad o^\theta_{\text{exit}}(l) = \begin{cases} m, & \text{if } l = \theta; \\ 0, & \text{otherwise}. \end{cases} \]
The process $(O^\theta_n)_{n \geq 0}$ always exits $W^* \setminus T^\theta$ at $o^\theta_{\text{exit}}$. This allows us to estimate the invariant measure with the help of the following renewal result.

**Proposition 6.2.** Let $(X_n)_{n \geq 0}$ be a discrete time Markov chain with values in a finite state space $E$ which is irreducible and aperiodic. Let $\mu$ be the invariant probability measure of the Markov chain $(X_n)_{n \geq 0}$. Let $W^*$ be a subset of $E$, and let $e$ be a point of $E \setminus W^*$. Let $f$ be a map from $E$ to $\mathbb{R}$ which vanishes on $E \setminus W^*$. Let
\[ \tau^* = \inf\{n \geq 0 : X_n \in W^*\}, \quad \tau = \inf\{n \geq \tau^* : X_n = e\}. \]
We have
\[ \sum_{x \in E} f(x) \mu(x) = \frac{1}{E(\tau|X_0 = e)} E\left(\sum_{n=\tau^*}^{\tau} f(X_n) \big| X_0 = e\right). \]

This result is proved in detail in [3]. We apply the renewal result of Proposition 6.2 to the process $(O^\theta_n)_{n \geq 0}$ restricted to $N \cup (W^* \setminus T^\theta)$, the set $W^* \setminus T^\theta$, the occupancy distribution $o^\theta_{\text{exit}}$ and the function $o \mapsto f(o(0)/m)$. Setting
\[ \tau^* = \inf\{n \geq 0 : O^\theta_n \in W^*\}, \quad \tau = \inf\{n \geq \tau^* : O^\theta_n = o^\theta_{\text{exit}}\}, \]
we have
\[ \sum_{o \in P_{\ell+1}^m} f\left(\frac{o(0)}{m}\right) \mu^\theta_O(o) = \frac{E(\sum_{n=\tau^*}^{\tau} f((O^\theta_n(0))/m)|O^\theta_0 = o^\theta_{\text{exit}})}{E(\tau|O^\theta_0 = o^\theta_{\text{exit}})}. \]

Yet, whenever the process $(O^\theta_n)_{n \geq 0}$ is in $W^* \setminus T^\theta$, the dynamics of the number of master sequences $(O^\theta_n(0))_{n \geq 0}$ is the same as the dynamics of the Markov
chain \((Z_n^\theta)_{n \geq 0}\) defined in Section 6.2. Let \(\tau_0\) be the hitting time of 0, defined by

\[ \tau_0 = \inf\{n \geq 0 : Z_n^\theta = 0\}. \]

The process \((O_n^\theta)_{n \geq 0}\) always exits \(W^\star \setminus T^\theta\) at \(o_{\text{exit}}^\theta\). Therefore \(\tau\) coincides with the exit time of \(W^\star \setminus T^\theta\) after \(\tau^\star\). Let \(i \in \{1, \ldots, m\}\). From the previous elements, we see that, conditionally on the event \(\{O_{\tau^\star}(0) = i\}\), the trajectory \((Z_n^\theta, 0 \leq n \leq \tau_0)\) starting from \(Z_0^\theta = i\), whence

\[ E(\tau - \tau^\star | O_{\tau^\star}(0) = i) = E(\tau_0 | Z_0^\theta = i), \]

\[ E\left(\sum_{n = \tau^\star}^{\tau} f\left(O_n^\theta(0)\right) | O_{\tau^\star}(0) = i\right) = E\left(\sum_{n = 0}^{\tau_0} f\left(Z_n^\theta/m\right) | Z_0^\theta = i\right). \]

Conditioning with respect to \(O_{\tau^\star}(0)\) and reporting in the formula for the invariant probability measure \(\mu^\theta_O\), we get

\[ \sum_{o \in P_{\ell+1}} f\left(o(0)/m\right) \mu^\theta_O(o) = \frac{\sum_{i = 1}^{m} E(\sum_{n = 0}^{\tau_0} f(Z_n^\theta/m) | Z_0^\theta = i) P(O_{\tau^\star}(0) = i | O_0^\theta = o_{\text{exit}}^\theta)}{E(\tau^\star | O_0^\theta = o_{\text{exit}}^\theta) + \sum_{i = 1}^{m} E(\tau_0 | Z_0^\theta = i) P(O_{\tau^\star}(0) = i | O_0^\theta = o_{\text{exit}}^\theta)}. \]

We must next estimate these expectations. In Section 7, we deal with the terms involving the Markov chain \((Z_n^\theta)_{n \geq 0}\). In Section 8, we deal with the discovery time \(\tau^\star\).

### 7. Approximating processes.
This section is devoted to the study of the dynamics of the Markov chains \((Z_n^\ell)_{n \geq 0}\) and \((Z_n^1)_{n \geq 0}\). The estimates are carried out exactly in the same way for both Markov chains. As we said before, the Markov chain \((Z_n^\theta)_{n \geq 0}\) corresponds to the evolution of the number of master sequences in a Wright–Fisher model with two types. Throughout the section, we fix \(\theta = 1 \) or \(\theta = \ell\), and we remove \(\theta\) from the notation in most places, writing simply \(p, Z_n\) instead of \(p^\theta, Z_n^\theta\).

**Asymptotic regime.** We shall derive estimates in the regime where

\[ \ell \to +\infty, \quad m \to +\infty, \quad q \to 0, \quad \ell q \to a \in ]0, +\infty[. \]

Several inequalities will be valid only when the parameters are sufficiently close to their limits. We will say that a property holds asymptotically to express that it holds for \(\ell, m\) large enough, \(q\) small enough and \(\ell q\) close enough to \(a\).
7.1. Large deviations for the transition matrix. For $p \in [0, 1]$ and $t \geq 0$, we define

$$I(p, t) = \begin{cases} 
\frac{t \ln t}{p} + (1 - t) \ln \frac{1 - t}{1 - p}, & 0 < p < 1, 0 \leq t \leq 1, \\
0, & t = p = 1, \\
+\infty, & (p \in \{0, 1\}, t \neq p) \text{ or } t > 1.
\end{cases}$$

The function $I(p, \cdot)$ is the rate function governing the large deviations of the binomial distribution $B(n, p)$ with parameters $n$ and $p$. We recall a basic estimate for the binomial coefficients.

**Lemma 7.1.** For any $n \geq 1$, any $k \in \{0, \ldots, n\}$, we have

$$\left| \ln \frac{n!}{k!(n - k)!} + k \ln \frac{k}{n} + (n - k) \ln \frac{n - k}{n} \right| \leq 2 \ln n + 3.$$

**Proof.** The proof is standard; see, for instance, [8]. Setting, for $n \in \mathbb{N}$, $\phi(n) = \ln n! - n \ln n + n$, we have

$$\ln \frac{n!}{k!(n - k)!} = \ln n! - \ln k! - \ln(n - k)!$$

$$= n \ln n - \phi(n) - (k \ln k - k + \phi(k))$$

$$- ((n - k) \ln(n - k) - (n - k) + \phi(n - k))$$

$$= -k \ln \frac{k}{n} - (n - k) \ln \frac{n - k}{n} + \phi(n) - \phi(k) - \phi(n - k).$$

Comparing the discrete sum $\ln n! = \sum_{1 \leq k \leq n} \ln k$ to the integral $\int_1^n \ln x \, dx$, we see that $1 \leq \phi(n) \leq \ln n + 2$ for all $n \geq 1$. On one hand,

$$\phi(n) - \phi(k) - \phi(n - k) \leq \ln n;$$

on the other hand,

$$\phi(n) - \phi(k) - \phi(n - k) \geq 1 - (\ln k + 2) - (\ln(n - k) + 2) \geq -3 - 2 \ln n,$$

and we have the desired inequalities. \qed

We define a function $f : [0, 1] \to [0, 1]$ by

$$f(r) = \frac{\sigma r}{(\sigma - 1)r + 1}$$

and a function $I_{t} : [0, 1]^4 \to [0, +\infty]$ by

$$I_{t}(r, s, \beta, t) = I(f(r), s) + sI\left(M_{H}(0, 0), \frac{\beta}{s}\right) + (1 - s)I\left(M_{H}(\theta, 0), \frac{t - \beta}{1 - s}\right).$$
The function $I_\ell$ depends on $\ell$ through the mutation probabilities $M_H(0,0)$ and $M_H(\theta,0)$. Using Lemma 7.1 and the expression of $p^\theta$, we see that

$$\ln p(h,i,j,k) = -mI_\ell\left(f\left(\frac{h}{m}, \frac{i}{m}\right), \frac{j}{i}\right) - (m-i)I_\ell\left(M_H(\theta,0), \frac{k-j}{m-i}\right) + \Phi(h,i,j,k,m)$$

$$= -mI_\ell\left(\frac{h}{m}, \frac{i}{m}, \frac{j}{m}, \frac{k}{m}\right) + \Phi(h,i,j,k,m),$$

where the error term $\Phi(h,i,j,k,m)$ satisfies

$$\forall h,i,j,k \in \{0, \ldots, m\} \quad |\Phi(h,i,j,k,m)| \leq 6 \ln m + 9.$$

In the asymptotic regime, for $\theta = 1$ or $\theta = \ell$, we have $M_H(0,0) \to e^{-a}$, $M_H(\theta,0) \to 0$, so that, for $r,s,\beta,t \in [0,1]^4$,

$$I_\ell(r,s,\beta,t) \to \begin{cases} I(r,s,t), & \text{if } \beta = t, \\ +\infty, & \text{if } \beta \neq t, \end{cases}$$

where the function $I(r,s,t)$ is given by

$$\forall r,s,t \in [0,1]^3 \quad I(r,s,t) = I(f(r),s) + sI\left(e^{-a}, \frac{t}{s}\right).$$

**Proposition 7.2.** We define a function $V_1$ on $[0,1] \times [0,1]$ by

$$\forall r,t \in [0,1] \quad V_1(r,t) = \inf\{I(r,s,t) : s \in [0,1]\}.$$

The one step transition probabilities of $(Z_n)_{n \geq 0}$ satisfy the large deviation principle governed by $V_1$: for $r \in [0,1]$ and any subset $U$ of $[0,1]$, we have, for any $n \geq 0$,

$$-\inf \{V_1(r,t) : t \in U^c\} \leq \liminf_{\ell,m \to \infty, q \to 0} \frac{1}{m} \ln P(Z_{n+1} \in mU | Z_n = \lfloor rm \rfloor),$$

$$\limsup_{\ell,m \to \infty, q \to 0} \frac{1}{m} \ln P(Z_{n+1} \in mU | Z_n = \lfloor rm \rfloor) \leq -\inf \{V_1(r,t) : t \in U\}. $$

**Proof.** Let $r \in [0,1]$, and let $U$ be a subset of $[0,1]$. For any $n \geq 0$,

$$P(Z_{n+1} \in mU | Z_n = \lfloor rm \rfloor) = \sum_{k \in mU \cap \{0, \ldots, m\}} p(\lfloor rm \rfloor, k)$$
\[
= \sum_{k \in \{0, \ldots, m\}} \sum_{i=0}^{m} \sum_{j=0}^{i} p(|rm|, i, j, k).
\]

From the previous inequalities, we have
\[
P(Z_{n+1} \in mU | Z_n = [rm]) \\
\leq (m + 1)^3 \max \{p(|rm|, i, j, k) : 0 \leq i \leq m, 0 \leq j \leq i, k \in mU\}
\leq m^{11} \exp \left( -m \min \left\{ I_{f}(\tfrac{rm}{m}, \tfrac{i}{m}, \tfrac{j}{m}, \tfrac{k}{m}) : 0 \leq j \leq i \leq m, k \in mU \right\} \right).
\]

For each \(m \geq 1\), let \(i_m, j_m, k_m\) be three integers in \(\{0, \ldots, m\}\) which realize the above minimum. By compactness of \([0, 1]\), up to the extraction of a subsequence, we can suppose that, as \(m\) goes to \(\infty\),
\[
i_m/m \rightarrow s, \quad j_m/m \rightarrow \beta, \quad k_m/m \rightarrow t.
\]
If \(\beta < t\), then
\[
\limsup_{\ell, m \to \infty, q \to 0} \ell q \rightarrow a - \inf \left\{ I_{f}(r, s, t) : s \in [0, 1], t \in U \right\}.
\]

Thus we need only to consider the case where \(\beta = t\). We have then
\[
\limsup_{\ell, m \to \infty, q \to 0} \ell q \rightarrow a - \inf \left\{ I_{f}(r, s, t) : s \in [0, 1], t \in U \right\}.
\]

This implies the large deviation upper bound
\[
\limsup_{\ell, m \to \infty, q \to 0} \frac{1}{m} \ln P(Z_{n+1} \in mU | Z_n = [rm]) \leq -\inf \{I(r, s, t) : s \in [0, 1], t \in U\}.
\]

Conversely, let \(s, t \in [0, 1]\). We have
\[
P(Z_{n+1} = [tm] | Z_n = [rm]) \\
\geq p([rm], [sm], [tm], [tm]) \\
\geq \frac{1}{m} \exp \left( -m I_{f}(\tfrac{rm}{m}, \tfrac{sm}{m}, \tfrac{tm}{m}, \tfrac{tm}{m}) \right)
\]
\[
\geq \frac{1}{m} \exp \left( -mI \left( f \left( \frac{\lfloor rm \rfloor}{m} \right), \frac{\lfloor sm \rfloor}{m} \right) - \lfloor sm \rfloor I \left( M_H(0, 0), \frac{tm}{\lfloor sm \rfloor} \right) \right)
- (m - \lfloor sm \rfloor) \ln \frac{1}{1 - M_H(\theta, 0)}. \]

Taking \( \ln \) and sending \( m, \ell \) to \( \infty \), we obtain

\[
\liminf_{\ell, m \to \infty, q \to 0} \frac{1}{\ell q} \ln P(Z_{n+1} = \lfloor tm \rfloor | Z_n = \lfloor rm \rfloor) \geq -I(r, s, t).
\]

Suppose now that \( t \) belongs to \( \partial U \), the interior of \( U \). For \( m \) large enough, the integer \( \lfloor tm \rfloor \) belongs to \( mU \). From the previous estimate, we have

\[
\liminf_{\ell, m \to \infty, q \to 0} \frac{1}{\ell q} \ln P(Z_{n+1} \in mU | Z_n = \lfloor rm \rfloor) \geq -I(r, s, t).
\]

Optimizing over \( s, t \), we get the large deviation lower bound

\[
\liminf_{\ell, m \to \infty, q \to 0} \frac{1}{\ell q} \ln P(Z_{n+1} \in mU | Z_n = \lfloor rm \rfloor) \geq -\inf \{I(r, s, t) : s \in [0, 1], t \in \partial U \}.
\]

This finishes the proof of the large deviation principle. \( \square \)

Proceeding in the same way, we can prove that the \( l \)-step transition probabilities satisfy a large deviation principle. For \( l \geq 1 \), we define a function \( V_l \) on \( [0, 1] \times [0, 1] \) by

\[
V_l(r, t) = \inf \left\{ \sum_{k=0}^{l-1} I(\rho_k, \gamma_k, \rho_{k+1}) : \rho_0 = r, \rho_l = t, \rho_k, \gamma_k \in [0, 1] \text{ for } 0 \leq k < l \right\}.
\]

**Corollary 7.3.** For \( l \geq 1 \), the \( l \)-step transition probabilities of \( (Z_n)_{n \geq 0} \) satisfy the large deviation principle governed by \( V_l \): for any subset \( U \) of \( [0, 1] \), any \( r \in [0, 1] \), we have, for any \( n \geq 0 \),

\[
-\inf \{V_l(r, t) : t \in \partial U \} \leq \liminf_{\ell, m \to \infty, q \to 0} \frac{1}{\ell q} \ln P(Z_{n+l} \in mU | Z_n = \lfloor rm \rfloor),
\]

\[
\limsup_{\ell, m \to \infty, q \to 0} \frac{1}{\ell q} \ln P(Z_{n+l} \in mU | Z_n = \lfloor rm \rfloor) \leq -\inf \{V_l(r, t) : t \in \partial U \}.
\]
Let us examine when the rate function \( I(r,s,t) \) vanishes. We see that
\[
I(r,s,t) = 0 \iff s = f(r), \quad e^{-a} = \frac{t}{s}.
\]
Let us define a function \( F: [0,1] \to [0,1] \) by
\[
\forall r \in [0,1] \quad F(r) = e^{-a}f(r) = \frac{\sigma e^{-a}}{(\sigma - 1)r + 1}.
\]
The Markov chain \((Z_n)_{n \geq 0}\) can be considered as a random perturbation of the dynamical system associated to the map \( F \)
\[
z_0 \in [0,1], \quad \forall n \geq 1 \quad z_n = F(z_{n-1}).
\]
Let us set
\[
\rho^*(a) = \begin{cases}
\frac{\sigma e^{-a} - 1}{\sigma - 1}, & \text{if } \sigma e^{-a} > 1, \\
0, & \text{if } \sigma e^{-a} \leq 1.
\end{cases}
\]
Since \( F \) is nondecreasing, the sequence \((z_n)_{n \in \mathbb{N}}\) is monotonous and it converges to a fixed point of \( F \). If \( \sigma e^{-a} \leq 1 \), the function \( F \) admits only one fixed point, 0, and \((z_n)_{n \in \mathbb{N}}\) converges to 0. If \( \sigma e^{-a} > 1 \), the function \( F \) admits two fixed points, 0 and \( \rho^*(a) \). If \( z_0 > 0 \), then \((z_n)_{n \in \mathbb{N}}\) converges to \( \rho^*(a) \).

The natural strategy to study the Markov chain \((Z_n)_{n \geq 0}\) is to use the Freidlin–Wentzell theory [10]. The crucial quantity to analyze the dynamics is the following cost function \( V \). We define, for \( s,t \in [0,1] \),
\[
V(s,t) = \inf_{l \geq 1} V_l(s,t)
\]
\[
= \inf_{l \geq 1} \inf \left\{ \sum_{k=0}^{l-1} I(\rho_k,\gamma_k,\rho_{k+1}) : \rho_0 = s, \rho_l = t, \rho_k, \gamma_k \in [0,1] \right. \\
\quad \left. \text{for } 0 \leq k < l \right\}.
\]

**Lemma 7.4.** Suppose that \( \sigma e^{-a} > 1 \). For \( s,t \in [0,1] \), we have \( V(s,t) = 0 \) if and only if:

- either \( s = t = 0 \),
- or there exists \( l \geq 1 \) such that \( t = F^l(s) \),
- or \( s \neq 0, t = \rho^*(a) \).

**Proof.** Throughout the proof we write \( \rho^* \) instead of \( \rho^*(a) \). Let \( s,t \in [0,1] \) be such that \( V(s,t) = 0 \). Suppose first that \( s = 0 \). Since \( I(0,\gamma,\rho) = +\infty \)
unless $\gamma = \rho = 0$, any sequence $(\rho_0, \gamma_0, \ldots, \gamma_l)$ such that $\rho_0 = s = 0$ and

$$\sum_{k=0}^{l-1} I(\rho_k, \gamma_k, \rho_{k+1}) < +\infty$$

has to be the null sequence, so that necessarily $t = 0$. We suppose next that $s > 0$. For each $n \geq 1$, let $(\rho_0^n, \gamma_0^n, \ldots, \rho_l(n))$ be a sequence of length $l(n)$ in $[0, 1]$ such that

$$p_0^n = s, p_l(n) = t, \quad \sum_{k=0}^{l(n)-1} I(p_k^n, \gamma_k^n, p_{k+1}^n) \leq \frac{1}{n}.$$ 

We consider two cases. If the sequence $(l(n))_{n \geq 1}$ is bounded, then we can extract a subsequence

$$(\phi(n), \rho_0^n, \gamma_0^n, \ldots, \rho_l(\phi(n)))$$

such that $l(\phi(n)) = l$ does not depend on $n$, and for any $k \in \{0, \ldots, l-1\}$, the following limits exist:

$$\lim_{n \to \infty} \rho_k^n = \rho_k, \quad \lim_{n \to \infty} \gamma_k^n = \gamma_k.$$ 

The map $I$ being continuous, we have then

$$\forall k \in \{0, \ldots, l-1\} \quad I(\rho_k, \gamma_k, \rho_{k+1}) = 0,$$

whence

$$\forall k \in \{0, \ldots, l\} \quad \rho_k = F^k(\rho_0).$$

Since in addition $\rho_0 = s$ and $\rho_l = t$, we conclude that $t = F^l(s)$. Suppose next that the sequence $(l(n))_{n \geq 1}$ is not bounded. Our goal is to show that $t = \rho^*$. Using Cantor’s diagonal procedure, we can extract a subsequence

$$(\phi(n), \rho_0^n, \gamma_0^n, \ldots, \rho_l(\phi(n)))$$

such that, for any $k \geq 0$, the following limits exist:

$$\lim_{n \to \infty} \rho_k^n = \rho_k, \quad \lim_{n \to \infty} \gamma_k^n = \gamma_k.$$ 

The map $I$ being continuous, we have then

$$\forall k \geq 0 \quad I(\rho_k, \gamma_k, \rho_{k+1}) = 0,$$

whence

$$\forall k \geq 0 \quad \rho_k = F^k(\rho_0).$$
We have $I(\rho^*, f(\rho^*), \rho^*) = 0$. Let $\varepsilon > 0$. The map $I$ being continuous, there exists a neighborhood $U$ of $\rho^*$ such that
\[
\forall \rho \in U \quad V_1(\rho^*, \rho) \leq I(\rho^*, f(\rho^*), \rho) < \varepsilon.
\]
Since $s > 0$, the sequence $(F^n(s))_{n \in \mathbb{N}}$ converges to $\rho^*$ and $F^h(s) \in U$ for some $h \geq 1$. In particular,
\[
\lim_{n \to \infty} \rho_n^{\phi(n)} = F^h(s) \in U,
\]
so that, for $n$ large enough, $\rho_n^{\phi(n)}$ is in $U$ and
\[
V(\rho^*, t) \leq V_1(\rho^*, \rho_n^{\phi(n)}) + V(\rho_n^{\phi(n)}, t) \leq \varepsilon + \frac{1}{n}.
\]
Letting successively $n$ go to $\infty$ and $\varepsilon$ go to 0, we obtain that $V(\rho^*, t) = 0$.

Let $\delta \in ]0, \rho^*/2[$, and let $U = ]\rho^* - \delta, \rho^* + \delta[$. Let $\alpha$ be the infimum
\[
\alpha = \inf\{I(\rho_0, \gamma_0, \rho_1) : \rho_0 \in \overline{U}, \gamma_0 \in [0, 1), \rho_1 \notin U\}.
\]
Since $I$ is continuous on the compact set $\overline{U} \times [0, 1] \times ([0, 1] \setminus U)$, then
\[
\exists (\rho_0^*, \gamma_0^*, \rho_1^*) \in \overline{U} \times [0, 1] \times ([0, 1] \setminus U) \quad \alpha = I(\rho_0^*, \gamma_0^*, \rho_1^*).
\]
The function $F$ is nondecreasing and continuous, therefore
\[
F(\overline{U}) = F([\rho^* - \delta, \rho^* + \delta]) = [F(\rho^* - \delta), F(\rho^* + \delta)].
\]
Moreover we have
\[
\rho^* - \delta < F(\rho^* - \delta) \leq F(\rho^* + \delta) < \rho^* + \delta.
\]
Thus $F(\overline{U}) \subset U$ and necessarily $\rho_1^* \neq F(\rho_0^*)$ and $\alpha > 0$. It follows that any sequence $(\rho_0, \gamma_0, \ldots, \rho_l)$ such that
\[
\rho_0 \in U, \quad \sum_{k=0}^{l-1} I(\rho_k, \gamma_k, \rho_{k+1}) < \alpha
\]
is trapped in $U$. As a consequence, a point $t$ satisfying $V(\rho^*, t) = 0$ must belong to $U$. This is true for any $\delta > 0$, hence for any neighborhood of $\rho^*$, thus $t = \rho^*$.  \(\square\)

### 7.2. Persistence time.

We recall that
\[
\tau_0 = \inf\{n \geq 0 : Z_n = 0\}.
\]
In this section, we will estimate the expected hitting time $\tau_0$ starting from a point of $\{1, \ldots, m\}$. This quantity approximates the persistence time of the master sequence $w^*$. 
Proposition 7.5. Let $a \in [0, +\infty[$ and let $i \in \{1, \ldots, m\}$. The expected hitting time $\tau_0$ of 0 starting from $i$ satisfies

$$\lim_{\ell, m \to \infty, q \to 0, \ell q \to a} \frac{1}{m} \ln E(\tau_0 | Z_0 = i) = V(\rho^*(a), 0).$$

Proof. Before proceeding to the proof, let us explain the general strategy, which comes directly from the theory of Freidlin and Wentzell. To obtain the upper bound on the persistence time, we show that, starting from any point in $\{1, \ldots, m\}$, the probability to reach a neighborhood of 0 in a finite number of steps is larger than

$$\exp(-mV(\rho^*, 0) + m\varepsilon).$$

This way we can bound from above $\tau_0$ by a geometric law with this parameter; see Lemma 7.6. To obtain the lower bound on the persistence time, we first show in Lemma 7.7 that, starting from any point, the process has a reasonable probability of reaching any neighborhood of $\rho^*$ before visiting 0. This estimate is quite tedious because the process might start from $Z_0 = 1$, which is close to the unstable fixed point of $F$. Since we need to control the hitting time of 0 starting from any point, such an estimate seems to be indispensable, and it cannot be done in the more general situations considered by Kifer [14] or Morrow and Sawyer [19] without adding some extra assumptions. So we give a lower bound on the probability of following the iterates of a discrete approximation of $F$. With a Poisson fluctuation, the process jumps away from 0, then, because $F$ is expanding in the neighborhood of 0, it reaches the point $\eta m$ after $\ln m$ steps, for some $\eta > 0$, and with a finite number of additional steps, it lands in a neighborhood of $\rho^*$. We study then the excursions of the process outside a neighborhood of 0 and $\rho^*$. Whenever the process is outside such a neighborhood, it reenters the neighborhood in a finite number of steps with probability larger than $1 - \exp(-cm)$ for some $c > 0$ depending on the neighborhood. Thus the process is very unlikely to stay a long time outside a neighborhood of the two attractors $\{0, \rho^*\}$. In fact, the length of an excursion outside a neighborhood of $\{0, \rho^*\}$ is bounded by a constant, up to a very unlikely event. We consider the hitting time $\tau_\delta$ of the $\delta$-neighborhood of 0. Obviously we have $\tau_0 \geq \tau_\delta$. We focus on the portion of the trajectory which starts at the last visit to a neighborhood of $\rho^*$ before reaching a neighborhood of 0. Such an excursion occurs at a given time with probability less than

$$\exp(-mV(\rho^*, 0) + m\varepsilon),$$

and therefore it is unlikely to occur before time $\exp(mV(\rho^*, 0) - m\varepsilon)$.

We start now with the implementation of this scheme. Throughout the proof we write $\rho^*$ instead of $\rho^*(a)$. We start by proving an upper bound
on the hitting time. The next argument works in both cases $se^{-a} \leq 1$ and $se^{-a} > 1$. In the case $se^{-a} \leq 1$, we have $\rho^* = 0$ and $V(\rho^*, 0) = 0$, and the proof becomes simpler, so there is no need to consider a path from $\rho^*$ to 0. We have $I(\rho^*, f(\rho^*), \rho^*) = 0$. Let $\varepsilon > 0$. The map $I$ being continuous, there exists $\delta > 0$ such that

$$\forall \rho \in ]\rho^* - \delta, \rho^* + \delta[ \quad I(\rho, f(\rho), \rho^*) < \varepsilon.$$

Moreover the sequence $(F^n(1))_{n \in \mathbb{N}}$ converges to $\rho^*$, thus

$$\exists h \geq 1 \quad F^h(1) \in ]\rho^* - \delta, \rho^* + \delta[.$$

Let $l \geq 1$ and let $(\rho_0, \gamma_0, \ldots, \rho_l)$ be a sequence in $[0, 1]$ such that

$$\rho_0 = \rho^*, \rho_l = 0, \quad \sum_{k=0}^{l-1} I(\rho_k, \gamma_k, \rho_{k+1}) \leq V(\rho^*, 0) + \varepsilon.$$

We consider the sequence obtained by concatenating the two previous sequences

$$t_0 = 1, \quad s_0 = f(1), \quad t_1 = F(1), \quad \ldots, \quad t_{h-1} = F^{h-1}(1),$$

$$s_{h-1} = f(t_{h-1}), \quad t_h = F^h(1), \quad s_h = f(t_h), \quad t_{h+1} = \rho^*, \quad s_{h+1} = \gamma_0,$$

$$t_{h+2} = \rho_1, \quad \ldots, \quad t_{h+l} = \rho_{l-1}, \quad s_{h+l} = \gamma_{l-1}, \quad t_{h+l+1} = \rho_l = 0.$$

We set $j = h + l + 1$. This sequence satisfies

$$t_0 = 1, t_j = 0, \quad \sum_{k=0}^{j-1} I(t_k, s_k, t_{k+1}) \leq V(\rho^*, 0) + 3\varepsilon.$$

We have then

$$P(Z_j = 0|Z_0 = m) \geq \prod_{k=0}^{j-1} p([mt_k], [ms_k], [mt_{k+1}], [mt_{k+1}]).$$

Taking ln, sending $m$ to $\infty$ and using the estimate on the transition probabilities obtained in the proof of Proposition 7.2, we have

$$\liminf_{\ell, m \to \infty, q \to 0} \frac{1}{m} \ln P(Z_j = 0|Z_0 = m) \geq - \sum_{k=0}^{j-1} I(t_k, s_k, t_{k+1}) \geq -V(\rho^*, 0) - 3\varepsilon.$$

Thus, asymptotically, we have

$$P(Z_j = 0|Z_0 = m) \geq \exp(-mV(\rho^*, 0) - 4m\varepsilon).$$
Using the monotonicity of the Markov chain \((Z_n)_{n \geq 0}\), we conclude that, asymptotically,

\[
\forall i \in \{1, \ldots, m\} \quad P(Z_j = 0 | Z_0 = i) \geq \exp(-mV(\rho^*, 0) - 4m\varepsilon).
\]

We have thus a lower bound on the probability of reaching 0 in \(j\) steps starting from any point in \(\{1, \ldots, m\}\). For any \(n \geq 0\), we have, using the Markov property,

\[
P(\tau_0 > (n+1)j | Z_0 = m) = \sum_{h=1}^{m} P(\tau_0 > (n+1)j, Z_{nj} = h | Z_0 = m)
\]

\[
= \sum_{h=1}^{m} P(\tau_0 > nj, Z_{nj} = h, Z_{nj+1} \neq 0, \ldots, Z_{(n+1)j} \neq 0 | Z_0 = m)
\]

\[
= \sum_{h=1}^{m} P(Z_{nj+1} \neq 0, \ldots, Z_{(n+1)j} \neq 0 | \tau_0 > nj, Z_{nj} = h, Z_0 = m)
\]

\[
\times P(\tau_0 > nj, Z_{nj} = h | Z_0 = m)
\]

\[
= \sum_{h=1}^{m} P(\tau_0 > j | Z_0 = h) P(\tau_0 > nj, Z_{nj} = h | Z_0 = m)
\]

\[
\leq (1 - \exp(-mV(\rho^*, 0) - 4m\varepsilon)) P(\tau_0 > nj | Z_0 = m).
\]

Iterating this inequality, we obtain the following result.

**Lemma 7.6.** For any \(\varepsilon > 0\), there exists \(j \geq 1\) such that

\[
\forall n \geq 0 \quad P(\tau_0 > nj | Z_0 = m) \leq (1 - \exp(-mV(\rho^*, 0) - 4m\varepsilon))^n.
\]

It follows that

\[
E(\tau_0 | Z_0 = m) = \sum_{n \geq 0} \sum_{k=nj+1}^{(n+1)j} P(\tau_0 \geq k | Z_0 = m)
\]

\[
\leq \sum_{n \geq 0} jP(\tau_0 > nj | Z_0 = m) \leq j \exp(mV(\rho^*, 0) + 4m\varepsilon),
\]

whence

\[
\limsup_{\varepsilon, m \to \infty, q \to 0} \frac{1}{m} \ln E(\tau_0 | Z_0 = m) \leq V(\rho^*, 0) + 4\varepsilon.
\]

Letting \(\varepsilon\) go to 0 yields the desired upper bound.
We compute next a lower bound on the hitting time. If \( \sigma e^{-a} \leq 1 \), then 
\[ \rho^* = 0, \quad V(\rho^*, 0) = 0, \]
and obviously,
\[ \lim \inf_{\ell, m \to \infty, q \to 0} \frac{1}{m} \ln E(\tau_0 | Z_0 = m) \geq V(\rho^*, 0) = 0. \]
Thus we need only to consider the case \( \sigma e^{-a} > 1 \). We start by estimating from below the probability of going from 1 to a neighborhood of \( \rho^* \) without visiting 0. Before proceeding with the mathematical details, let us explain the strategy to get this lower bound. When \( Z_0 = 1 \), the binomial law involved in the replication mechanism can be approximated by a Poisson law of parameter \( \sigma \), and the process \( (Z_n)_{n \geq 0} \) can jump to any fixed \( h \in \mathbb{N} \) with a probability larger than a positive quantity independent of \( m \). Using a simple estimate on the central term of the binomial law, we have that
\[ P(Z_{n+1} = G(h) | Z_n = h) \geq \frac{1}{(m + 1)^2}, \]
where \( G \) is a map from \( \{0, \ldots, m\} \) to \( \{0, \ldots, m\} \) such that
\[ \frac{1}{m} G(h) \geq F \left( \frac{h}{m} \right) - \frac{1}{m}. \]
We study then the iterates of the function \( F(x) - 1/m \). This function, which is a small perturbation of \( F \), has two fixed points, one unstable close to 0, of order \( 1/m \), and one stable close to \( \rho^* \). We take \( h \) large enough so that \( h/m \) is larger than the unstable fixed point. Then the repulsive dynamics of \( F(x) - 1/m \) will bring the point \( h/m \) close to a value \( \eta > 0 \) (independent of \( m \)) in a number of iterates of order \( \ln m \). Once the process \( (Z_n)_{n \geq 0} \) is at \( \lfloor \eta m \rfloor \), a finite number of iterates leads into the neighborhood of \( \rho^* \). The lower bound is obtained by combining the three steps
\[ P(1 \to h) P(h \to \eta m) P(\eta m \to (\rho^* - \delta)m) \geq c \left( \frac{1}{(m + 1)^2} \right)^{c \ln m + c} \]
where \( c \) is a constant independent of \( m \). This is the idea of the proof of the next lemma.

**Lemma 7.7.** For any \( \delta > 0 \), there exists \( c > 0 \), depending on \( \delta \), such that, asymptotically,
\[ P(Z_1 > 0, \ldots, Z_{\lfloor c \ln m \rfloor - 1} > 0, Z_{\lfloor c \ln m \rfloor} > m(\rho^* - \delta) | Z_0 = 1) \geq \frac{1}{m^{c \ln m}}. \]

**Proof.** The binomial law \( B(n, p) \) of parameters \( n \geq 0 \) and \( p < 1 \) is maximal at \( \lfloor (n + 1)p \rfloor \), therefore
\[ \left( \begin{array}{c} n \\ \lfloor (n + 1)p \rfloor \end{array} \right) p^{\lfloor (n + 1)p \rfloor} (1 - p)^{n - \lfloor (n + 1)p \rfloor} \geq \frac{1}{n + 1}. \]
See, for instance, Chapter VI in Feller’s book [9]. We shall use this inequality to bound from below the transition probabilities of the Markov chain \((Z_n)_{n\geq 0}\). Let us define a map \(G: \{0, \ldots, m\} \to \{0, \ldots, m\}\) by

\[
G(h) = \left\lceil \left( (m+1)f\left(\frac{h}{m}\right) + 1 \right) M_H(0,0) \right\rceil,
\]

\[
G(m) = \left\lfloor (m+1)M_H(0,0) \right\rfloor.
\]

The map \(G\) depends on the parameters \(m, \ell\) and \(q\). Applying the previous lower bound to the binomial laws involved in the transition step of \((Z_n)_{n\geq 0}\), we obtain

\[
\forall n, h \geq 0 \quad P(Z_{n+1} \geq G(h) | Z_n = h)
\]

\[
\geq \sum_{k \geq G(h)} p\left(h, \left( (m+1)f\left(\frac{h}{m}\right) \right), G(h), k\right)
\]

\[
\geq \frac{1}{(m+1)^2}.
\]

It follows that for \(n, h \geq 0\),

\[
P(Z_1 \geq G^1(h), \ldots, Z_n \geq G^n(h) | Z_0 = h)
\]

\[
= \sum_{l \geq G^{n-1}(h)} P(Z_1 \geq G^1(h), \ldots, Z_{n-1} = l, Z_n \geq G^n(h) | Z_0 = h)
\]

\[
= \sum_{l \geq G^{n-1}(h)} P(Z_n \geq G^n(h) | Z_{n-1} = l)
\]

\[
\times P(Z_1 \geq G^1(h), \ldots, Z_{n-1} = l | Z_0 = h)
\]

\[
\geq P(Z_n \geq G^n(h) | Z_{n-1} = G^{n-1}(h))
\]

\[
\times P(Z_1 \geq G^1(h), \ldots, Z_{n-1} \geq G^{n-1}(h) | Z_0 = h)
\]

\[
\geq \frac{1}{(m+1)^2} P(Z_1 \geq G^1(h), \ldots, Z_{n-1} \geq G^{n-1}(h) | Z_0 = h).
\]

Iterating this inequality, we obtain, for \(n, h \geq 0\),

\[
P(Z_1 \geq G^1(h), \ldots, Z_n \geq G^n(h) | Z_0 = h) \geq \frac{1}{(m+1)^{2n}}.
\]

The map \(G\) is nondecreasing. Moreover, for \(h \in \{0, \ldots, m\}\),

\[
G(h) \geq \left\lfloor (m+1)f\left(\frac{h}{m}\right) M_H(0,0) \right\rfloor \geq m f\left(\frac{h}{m}\right) M_H(0,0) - 1.
\]

Let us define a map \(H: [0, 1] \to [0, 1]\) by

\[
\forall x \in [0, 1] \quad H(x) = e^{a} M_H(0,0) F(x) - \frac{1}{m}.
\]
We can rewrite the previous inequality as

\[ \forall h \in \{0, \ldots, m\} \quad G(h) \geq mH \left( \frac{h}{m} \right). \]

Iterating this inequality, we get, thanks to the fact that both \( G \) and \( H \) are nondecreasing,

\[ \forall n \geq 0, \forall h \in \{0, \ldots, m\} \quad G^n(h) \geq mH^n \left( \frac{h}{m} \right). \]

The map \( H \), which is a small perturbation of the map \( F \), has two fixed points \( \rho' < \rho'' \), whose expansion is given by

\[ \rho' = \frac{1}{m(\sigma M_H(0,0) - 1)} + o \left( \frac{1}{m} \right), \]
\[ \rho'' = \frac{\sigma M_H(0,0) - 1}{\sigma - 1} - \frac{\sigma M_H(0,0)}{m(\sigma M_H(0,0) - 1)} + o \left( \frac{1}{m} \right). \]

Notice that \( M_H(0,0) \) converges to \( e^{-a} \), so \( \rho' \) is close to 0 and \( \rho'' \) is close to \( \rho^* \). Let \( \eta > 0 \). If \( x \leq \eta \), we have \( F(x) \geq \alpha x \), where

\[ \alpha = \frac{\sigma e^{-a}}{(\sigma - 1)\eta + 1}. \]

For \( \eta \) sufficiently small, we have \( \alpha > 1 \) and the map \( F \) restricted to \([0, \eta]\) is expanding. Let \( \beta = (1 + \alpha)/2 \). Asymptotically, we have \( \alpha e^a M_H(0,0) \geq \beta \).

Let us study the iterates of \( x \) through the map \( H \). We set

\[ N = \inf \{ n \geq 0 : H^n(x) > \eta \}. \]

For \( 1 \leq n < N \), we have then

\[ H^n(x) = H(H^{n-1}(x)) \geq \beta H^{n-1}(x) - \frac{1}{m}, \]

which we rewrite as

\[ \frac{1}{\beta^n} H^n(x) \geq \frac{1}{\beta^{n-1}} H^{n-1}(x) - \frac{1}{m \beta^{n-1}}. \]

Summing from \( n = 1 \) to \( N - 1 \), we get

\[ H^{N-1}(x) \geq \beta^{N-1} \left( x - \frac{1}{m} \sum_{n=0}^{N-2} \frac{1}{\beta^n} \right) \geq \beta^{N-1} \left( x - \frac{\beta}{m(\beta - 1)} \right). \]

Let \( h \) be an integer such that

\[ h \geq 2 \frac{\beta}{\beta - 1}. \]
Notice that this condition does not depend on \( m \). We suppose that \( m > h \).
We take \( x = h/m \), and we denote by \( N(h) \) the associated integer. From the previous inequalities, we have then
\[
\eta \geq H^{N(h)-1}\left(\frac{h}{m}\right) \geq \beta^{N(h)-1} \frac{h}{2m}.
\]
Thus \( N(h) \) satisfies
\[
N(h) \leq 1 + \frac{1}{\ln \beta} \ln \frac{2m\eta}{h},
\]
and we have, asymptotically,
\[
P(Z_1 > 0, \ldots, Z_{N(h)-1} > 0, Z_{N(h)} > m\eta|Z_0 = h)
\geq P\left( Z_1 \geq mH^1\left(\frac{h}{m}\right), \ldots, Z_{N(h)} \geq mH^{N(h)}\left(\frac{h}{m}\right) | Z_0 = h \right)
\geq P(Z_1 \geq G^1(h), \ldots, Z_{N(h)} \geq G^{N(h)}(h)|Z_0 = h)
\geq \frac{1}{(m+1)^{2N(h)}}.
\]
We control next the probability to go from 1 to \( h \). We have
\[
P(Z_1 \geq h|Z_0 = 1) \geq \left(\frac{m}{h}\right) \frac{\sigma^h(m-1)^{m-h}}{(\sigma - 1 + m)^m} M_H(0,0)^h.
\]
In this regime, where \( h \) is fixed and \( m \) is large, the binomial law involved in the replication mechanism can be approximated by a Poisson law of parameter \( \sigma \), whence, asymptotically,
\[
P(Z_1 \geq h|Z_0 = 1) \geq \frac{1}{2} \exp(-\sigma) \frac{\sigma^h}{h!} \exp(-ah).
\]
We control finally the probability to go from \( \eta m \) to the neighborhood of \( \rho^* \). We do this by following the iterates of \( F \) starting from \( \eta \), and by controlling the error term with respect to the iterates of \( H \).

**Lemma 7.8.** We suppose that \( \sigma e^{-a} > 1 \). For \( n \geq 0 \), \( x \in [0,1] \), we have
\[
H^n(x) \geq (e^a M_H(0,0) F)^n(x) - \frac{1}{m} \frac{(\sigma M_H(0,0))^{n+1}}{\sigma M_H(0,0) - 1}.
\]

**Proof.** We have
\[
\forall x \in [0,1] \quad |F'(x)| \leq \sigma e^{-a},
\]
and, for any \( n \geq 0 \),
\[
H^{n+1}(x) = H(H^n(x)) = e^a M_H(0,0) F(H^n(x)) - \frac{1}{m}.
\]
We shall prove the following inequality by induction on $n$:

$$H^n(x) \geq (e^a M_H(0,0) F)^n(x) - \frac{1}{m} \sum_{k=1}^{n} (\sigma M_H(0,0))^k.$$ 

The inequality is true for $n = 0, 1$. Suppose that the inequality holds for some $n \geq 0$. Since $F$ is nondecreasing, we deduce from the inequality on $F'$ and the mean value theorem that

$$H^{n+1}(x) \geq e^a M_H(0,0) F \left( (e^a M_H(0,0) F)^n(x) - \frac{1}{m} \sum_{k=1}^{n} (\sigma M_H(0,0))^k \right) - \frac{1}{m}$$

$$\geq (e^a M_H(0,0) F)^{n+1}(x) - \sigma M_H(0,0) \frac{1}{m} \sum_{k=1}^{n} (\sigma M_H(0,0))^k - \frac{1}{m}$$

$$\geq (e^a M_H(0,0) F)^{n+1}(x) - \frac{1}{m} \sum_{k=1}^{n+1} (\sigma M_H(0,0))^k,$$

and the inequality is proved at rank $n + 1$. Summing the geometric series, we obtain the inequality stated in the lemma. □

Let $\delta > 0$. The sequence $(F^n(\eta))_{n \in \mathbb{N}}$ converges to $\rho^*$, thus $F^t(\eta) > \rho^* - \delta$ for some $t \geq 1$. For $m$ large enough, we have also

$$(e^a M_H(0,0) F)^t(\eta) - \frac{1}{m} \frac{(\sigma M_H(0,0))^{t+1}}{\sigma M_H(0,0) - 1} > \rho^* - \delta,$$

and Lemma 7.8 implies that $H^t(\eta) > \rho^* - \delta$. Let $i$ be an integer strictly larger than $\eta m$. We have

$$P(Z_1 > 0, \ldots, Z_{t-1} > 0, Z_t > m(\rho^* - \delta)|Z_0 = i)$$

$$\geq P(Z_1 \geq m H^1(\eta), \ldots, Z_t \geq m H^t(\eta)|Z_0 = i)$$

$$\geq P \left( Z_1 \geq m H^1 \left( \frac{i}{m} \right), \ldots, Z_t \geq m H^t \left( \frac{i}{m} \right) | Z_0 = i \right)$$

$$\geq P(Z_1 \geq G^1(i), \ldots, Z_t \geq G^t(i) | Z_0 = i)$$

$$\geq \frac{1}{(m+1)^{2t}}.$$

To conclude, we use the monotonicity of $(Z_n)_{n \geq 0}$, and we combine the three previous estimates. The values $h, t$ do not depend on $m$, and there exists a positive constant $c$ depending on $\eta, h$ such that, asymptotically,

$$N(h) + t + 1 < c \ln m,$$

$$\left( \frac{1}{2} \exp(-\sigma \frac{h}{m}) \exp(-ah) \right)^{c \ln m} \frac{1}{(m+1)^{2N(h)+2t}} \geq \frac{1}{m^c \ln m}.$$
Let us set \( s = |\lceil \ln m \rceil - (N(h) + t) \). Recall that \( t \) depends on \( \eta, \delta \) and \( h \) depends on \( \eta \). We have

\[
P(Z_1 > 0, \ldots, Z_{\lceil \ln m \rceil - 1} > 0, Z_{\lceil \ln m \rceil} > m(\rho^* - \delta)|Z_0 = 1) 
\geq \sum_{j > h} \sum_{i > m\eta} P(Z_1 \geq h, \ldots, Z_{s-1} \geq h, Z_s = j, Z_{s+1} > 0, \ldots, Z_{s+N(h)-1} > 0, \]
\[
Z_{s+N(h)} = i, Z_{s+N(h)+1} > 0, \ldots, Z_{s+N(h)+t-1} > 0, \]
\[
Z_{s+N(h)+t} > m(\rho^* - \delta)|Z_0 = 1
\]
\[
\geq \sum_{j > h} \sum_{i > m\eta} P(Z_1 \geq h, \ldots, Z_{s-1} \geq h, Z_s = j | Z_0 = 1)
\times P(Z_{s+1} > 0, \ldots, Z_{s+N(h)-1} > 0, Z_{s+N(h)} = i | Z_s = j)
\times P(Z_{s+N(h)+1} > 0, \ldots, Z_{s+N(h)+t-1} > 0,
Z_{s+N(h)+t} > m(\rho^* - \delta)|Z_{s+N(h)} = i)
\geq P(Z_1 \geq h, \ldots, Z_s \geq h | Z_0 = 1)
\times \sum_{i > m\eta} P(Z_1 > 0, \ldots, Z_{N(h)-1} > 0, Z_{N(h)} = i | Z_0 = h)
\times P(Z_1 > 0, \ldots, Z_{t-1} > 0, Z_t > m(\rho^* - \delta)|Z_0 = i)
\geq (P(Z_1 \geq h | Z_0 = 1))^s
\times P(Z_1 > 0, \ldots, Z_{N(h)-1} > 0, Z_{N(h)} > m\eta | Z_0 = h) \frac{1}{(m+1)^{2t}}
\geq \left( \frac{1}{2} \exp(-\sigma) \frac{\sigma^h}{h!} \exp(-ah) \right)^s \frac{1}{(m+1)^{2N(h)+2t}} \geq \frac{1}{m^{c\ln m}}.
\]

This is the required lower bound. \( \square \)

Whenever the starting point is far away from 0, the estimate of Lemma 7.7 can be considerably enhanced, as shown in the next lemma.

**Lemma 7.9.** We suppose that \( \sigma e^{-a} > 1 \). For any \( \delta > 0 \), there exist \( h \geq 1 \) and \( c > 0 \), depending on \( \delta \), such that, asymptotically,

\[
P(Z_1 > 0, \ldots, Z_{h-1} > 0, Z_h > m(\rho^* - \delta)|Z_0 = [m\delta]) \geq 1 - \exp(-cm).
\]

**Proof.** Let \( \delta > 0 \). The sequence \( (F^n(\delta))_{n \in \mathbb{N}} \) converges to \( \rho^* \). Thus there exists \( h \geq 1 \) such that \( F^h(\delta) > \rho^* - \delta \). By continuity of the map \( F \), there exist \( \rho_0, \rho_1, \ldots, \rho_h > 0 \) such that \( \rho_0 = \delta, \rho_h > \rho^* - \delta \) and

\[
\forall k \in \{1, \ldots, h\} \quad F(\rho_{k-1}) > \rho_k.
\]
Now,

\[ P(Z_1 > 0, \ldots, Z_{h-1} > 0, Z_h > m(\rho^* - \delta)|Z_0 = \lfloor m\delta \rfloor) \geq P(\forall k \in \{1, \ldots, h\}, Z_k \geq m\rho_k|Z_0 = \lfloor m\delta \rfloor). \]

Passing to the complementary event, we have

\[ P(\exists k \in \{1, \ldots, h-1\}, Z_k = 0 \text{ or } Z_h \leq m(\rho^* - \delta)|Z_0 = \lfloor m\delta \rfloor) \leq P(\exists k \in \{1, \ldots, h\}, Z_k < m\rho_k|Z_0 = \lfloor m\delta \rfloor). \]

The large deviation principle for the transition probabilities of the Markov chain \((Z_n)_{n \geq 0}\) stated in Proposition 7.2 implies that for \(k \in \{1, \ldots, h\},\)

\[ \limsup_{\ell, m \to \infty, q \to 0} \frac{1}{m} \ln P(Z_1 < m\rho_k|Z_0 = \lfloor m\rho_{k-1} \rfloor) \leq -\inf \{I(\rho_{k-1}, s, t) : s \in [0,1], t \leq \rho_k\} < 0. \]

Since \(h\) is fixed, we conclude that

\[ \limsup_{\ell, m \to \infty, q \to 0} \frac{1}{m} \ln P(\exists k \in \{1, \ldots, h-1\}, Z_k = 0 \text{ or } Z_h \leq m(\rho^* - \delta)|Z_0 = \lfloor m\delta \rfloor) < 0, \]

and this yields the desired estimate. \(\square\)

With the estimate of Lemma 7.9, we show that the process is very unlikely to stay a long time in \([m\delta, m(\rho^* - \delta)].\)

**Corollary 7.10.** We suppose that \(\sigma e^{-a} > 1.\) Let \(\delta > 0.\) There exist \(h \geq 1\) and \(c > 0\) such that, asymptotically,

\[ \forall k \in [m\delta, m(\rho^* - \delta)], \forall n \geq 0 \]

\[ P(m\delta \leq Z_t \leq m(\rho^* - \delta) \text{ for } 0 \leq t \leq n|Z_0 = k) \leq \exp \left( -cm \frac{n}{h} \right). \]
Proof. Let \( k \in [m\delta, m(\rho^* - \delta)] \). Let \( \delta > 0 \), and let \( h \geq 1 \) and \( c > 0 \) be associated to \( \delta \) as in Lemma 7.9. We divide the interval \( \{0, \ldots, n\} \) into subintervals of length \( h \), and we use repeatedly the estimate of Lemma 7.9. Let \( i \geq 0 \). We write

\[
P(m\delta \leq Z_t \leq m(\rho^* - \delta) \text{ for } 0 \leq t \leq (i+1)h|Z_0 = k) = \sum_{\delta m \leq j \leq (\rho^* - \delta)m} \frac{P(m\delta \leq Z_t \leq m(\rho^* - \delta) \text{ for } 0 \leq t \leq ih|Z_{ih} = j|Z_0 = k)}{
\sum_{\delta m \leq j \leq (\rho^* - \delta)m} P(m\delta \leq Z_t \leq m(\rho^* - \delta) \text{ for } 0 \leq t \leq ih|Z_{ih} = j|Z_0 = k)}
\]

\[
\leq \frac{P(m\delta \leq Z_t \leq m(\rho^* - \delta) \text{ for } 0 \leq t \leq ih|Z_{ih} = j|Z_0 = k)}{P(Z_h \leq m(\rho^* - \delta)|Z_0 = \lfloor m\delta \rfloor)} \exp(-cm).
\]

Iterating this inequality, we obtain

\[
\forall i \geq 0 \quad P(m\delta \leq Z_t \leq m(\rho^* - \delta) \text{ for } 0 \leq t \leq ih|Z_0 = k) \leq \exp(-cmi).
\]

The claim of the corollary follows by applying this inequality with \( i \) equal to the integer part of \( n/h \). \( \square \)

We have computed the relevant estimates to reach the neighborhood of \( \rho^* \). Our next goal is to study the hitting time \( \tau_0 \) starting from a neighborhood of \( \rho^* \). Since we need only a lower bound, we shall study the hitting time of a neighborhood of 0. For \( \delta > 0 \), we define

\[\tau_\delta = \inf\{n \geq 0 : Z_n < m\delta\}.\]

Let \( i > (\rho^* - \delta)m \). We shall estimate the expectation of \( \tau_\delta \) starting from \( i \). The strategy consists of looking at the portion of the trajectory starting at the last visit to the neighborhood of \( \rho^* \) before reaching the neighborhood of 0. Accordingly, we define

\[S = \max\{n \leq \tau_\delta : Z_n > (\rho^* - \delta)m\}\]

Notice that \( S \) is not a Markov time. We write, for \( n, k \geq 1 \),

\[
P(\tau_\delta \leq n|Z_0 = i) = \sum_{1 \leq s < t \leq n} P(\tau_\delta = t, S = s|Z_0 = i)
\]
\[
R. CERF = \sum_{1 \leq s < t \leq n} P(\tau_\delta = t, S = s | Z_0 = i) + \sum_{1 \leq s < n \atop s + k < t \leq n} P(\tau_\delta = t, S = s | Z_0 = i).
\]

Let \( h \geq 1 \) and \( c > 0 \) be associated to \( \delta \) as in Corollary 7.10. For \( 1 \leq s < n \) and \( t > s + k \),
\[
P(\tau_\delta = t, S = s | Z_0 = i)
= \sum_{m\delta \leq j \leq (\rho^* - \delta)m} P(\tau_\delta = t, S = s, Z_{s+1} = j | Z_0 = i)
\leq \sum_{m\delta \leq j \leq (\rho^* - \delta)m} P \left( \delta m \leq Z_r \leq (\rho^* - \delta)m \text{ for } s + 1 \leq r \leq t - 1 \mid Z_{s+1} = j \right)
\leq m \exp \left( -cm \left[ \frac{t - s - 2}{h} \right] \right),
\]
whence
\[
\sum_{1 \leq s < n \atop s + k < t \leq n} P(\tau_\delta = t, S = s | Z_0 = i) \leq n \sum_{t \geq k} m \exp \left( -cm \left[ \frac{t - 1}{h} \right] \right).
\]

For \( 1 \leq s < t \leq n \) and \( t \leq s + k \),
\[
P(\tau_\delta = t, S = s | Z_0 = i)
\leq \sum_{j > (\rho^* - \delta)m} P(\tau_\delta = t, S = s, Z_s = j | Z_0 = i)
\leq \sum_{j > (\rho^* - \delta)m} P(Z_t < \delta m | Z_s = j)
\leq m P(Z_{t-s} < \delta m | Z_0 = \lfloor (\rho^* - \delta)m \rfloor),
\]
whence
\[
\sum_{1 \leq s < n \atop s < t \leq s + k} P(\tau_\delta = t, S = s | Z_0 = i) \leq n \sum_{1 \leq t \leq k} m P(Z_t < \delta m | Z_0 = \lfloor (\rho^* - \delta)m \rfloor).
\]

Putting together the previous inequalities, we obtain
\[
P(\tau_\delta \leq n | Z_0 = i) \leq n \sum_{t \geq k} m \exp \left( -cm \left[ \frac{t - 1}{h} \right] \right)
+ n \sum_{1 \leq t \leq k} m P(Z_t < \delta m | Z_0 = \lfloor (\rho^* - \delta)m \rfloor).
\]
We choose $k$ large enough so that
\[
\limsup_{\ell,m \to \infty, q \to 0} \frac{1}{m} \ln \left( \sum_{t \geq k} m \exp \left( -cm \left[ \frac{t-1}{h} \right] \right) \right) < -V(\rho^* - \delta, \delta),
\]
and we use the large deviation principle stated in Corollary 7.3 to estimate the second sum,
\[
\limsup_{\ell,m \to \infty, q \to 0} \frac{1}{m} \ln \left( \sum_{1 \leq t \leq k} mP(Z_t < \delta m | Z_0 = [(\rho^* - \delta)m]) \right)
\leq \min_{1 \leq t \leq k} V_t(\rho^* - \delta, \delta) \leq -V(\rho^* - \delta, \delta).
\]
Applying the previous inequalities with $n = \exp(mV(\rho^* - \delta, \delta) - m\delta)$, we conclude that
\[
\lim_{\ell,m \to \infty, q \to 0} P(\tau_0 \leq \exp(mV(\rho^* - \delta, \delta) - m\delta) | Z_0 = i) = 0
\]
and therefore
\[
\liminf_{\ell,m \to \infty, q \to 0} \frac{1}{m} \ln E(\tau_0 | Z_0 = i) \geq V(\rho^* - \delta, \delta) - \delta.
\]
To derive a lower bound on the expectation of $\tau_0$ starting from 1, we combine the previous estimates as follows. By Lemma 7.7, asymptotically,
\[
P(Z_1 > 0, \ldots, Z_{\lfloor \ln m \rfloor - 1} > 0, Z_{\lfloor \ln m \rfloor} > m(\rho^* - \delta) | Z_0 = 1) \geq \frac{1}{m^{\lfloor \ln m \rfloor}}.
\]
Thus, letting $i = [(\rho^* - \delta)m] + 1$, for any $n \geq \lfloor \ln m \rfloor$,
\[
P(\tau_0 > n | Z_0 = 1) \geq \sum_{j \geq i} P(Z_1 > 0, \ldots, Z_{\lfloor \ln m \rfloor - 1} > 0, Z_{\lfloor \ln m \rfloor} = j | \tau_0 > n | Z_0 = 1)
\geq \sum_{j \geq i} P(Z_1 > 0, \ldots, Z_{\lfloor \ln m \rfloor - 1} > 0, Z_{\lfloor \ln m \rfloor} = j | Z_0 = 1)
\times P(Z_{\lfloor \ln m \rfloor + 1} > 0, \ldots, Z_n > 0 | Z_{\lfloor \ln m \rfloor} = j)
\geq P(Z_1 > 0, \ldots, Z_{\lfloor \ln m \rfloor - 1} > 0, Z_{\lfloor \ln m \rfloor} > m(\rho^* - \delta) | Z_0 = 1)
\times P(Z_{\lfloor \ln m \rfloor + 1} > 0, \ldots, Z_n > 0 | Z_{\lfloor \ln m \rfloor} = i)
\geq \frac{1}{m^{\lfloor \ln m \rfloor}} P(\tau_0 > n - \lfloor \ln m \rfloor | Z_0 = i).
Summing from $n = \lfloor c \ln m \rfloor$ to $+\infty$, we get

$$
E(\tau_0 | Z_0 = 1) \geq \frac{1}{m^c \ln m} E(\tau_0 | Z_0 = i).
$$

The very definition of $\tau_0$ implies that $\tau_0 \geq \tau_0$, whence

$$
E(\tau_0 | Z_0 = i) \geq E(\tau_0 | Z_0 = i).
$$

From the lower bound on $\tau_0$ and the previous inequalities, we deduce that

$$
\liminf_{\ell,m \to \infty, q \to 0} \frac{1}{\ell q} \ln E(\tau_0 | Z_0 = 1) \geq V(\rho^* - \delta, \delta) - \delta.
$$

The conclusion follows by letting $\delta$ go to 0. □

7.3. Concentration near $\rho^*$. In this section, we estimate the numerator of the last formula of Section 6.3. As usual, we drop the superscript $\theta$ from the notation when it is not necessary, and we put it back when we need to emphasize the differences between the cases $\theta = \ell$ and $\theta = 1$. Let $f : [0, 1] \to \mathbb{R}$ be a nondecreasing continuous function such that $f(0) = 0$. Our goal here is to estimate the expected value of the sum

$$
\sum_{n=0}^{\tau_0} f\left(\frac{Z_n}{m}\right).
$$

The Markov chain $(Z_n)_{n \geq 0}$ is a perturbation of the dynamical system associated to the map $F$, and therefore it spends most of its time in the neighborhood of the stable fixed point $\rho^*$. On very large time intervals, the process visits points far away from $\rho^*$, and then it returns quickly to $\rho^*$. From this picture, we conclude that the fraction of the time spent away from $\rho^*$ is negligible. We will show that the above sum is, on average, comparable to $f(\rho^*) \tau_0$.

**Proposition 7.11.** We suppose that $\sigma e^{-a} > 1$. We have, uniformly with respect to $i \in \{1, \ldots, m\}$,

$$
\lim_{\ell,m \to \infty, q \to 0} \frac{E(\sum_{n=0}^{\tau_0} f(Z_n/m) | Z_0 = i)}{E(\tau_0 | Z_0 = i)} = f(\rho^*).
$$

**Proof.** Before proceeding to the proof, let us explain the general strategy, which comes directly from the theory of Freidlin and Wentzell. For $\delta > 0$, we denote by $U(\delta)$ the $\delta$-neighborhood of $\rho^*$,

$$
U(\delta) = [\rho^* - \delta, \rho^* + \delta[.
$$
We choose \( \delta \) small enough, so that when the process is in \( U(2\delta) \), the value \( f(Z_n/m) \) is approximated by \( f(\rho^*) \). When the process is outside of \( \{0\} \cup U(2\delta) \), it reenters \( U(\delta) \) in \( |c \ln m| \) steps with probability at least \( m^{-c \ln m} \), for some \( c > 0 \); see Lemma 7.14. Therefore the average length of an excursion is bounded by \( mc \ln m \). At a given time, the probability to start an excursion from \( U(\delta) \) reaching the outside of \( U(2\delta) \) is less than \( \exp(-cm) \), for some \( c > 0 \). With this estimate we can control the number of these excursions (see Lemma 7.13), and we show that, typically, their total length until the time \( \tau_0 \) is negligible compared to \( \tau_0 \).

We start now the detailed proof. Let \( \varepsilon > 0 \). Since \( f \) is continuous, there exists \( \delta > 0 \) such that

\[
\forall \rho \in U(2\delta) \quad |f(\rho) - f(\rho^*)| < \varepsilon.
\]

We define then a sequence of stopping times in order to track the excursions of \( (Z_n)_{n \geq 0} \) outside \( U(\delta) \). More precisely, we set

\[
T_0 = 0 \quad \text{and} \quad T_{k^*} = \inf \left\{ n \geq T_{k-1}: \frac{Z_n}{m} \notin U(\delta) \right\},
\]

where

\[
T_k = \inf \left\{ n \geq T_{k-1}: \frac{Z_n}{m} \in U(\delta) \right\},
\]

Next, we decompose the sum over the intervals \( [T_{k-1}, T_k^*], [T_k^*, T_k[ \), \( k \geq 1 \). Denoting by \( s \land t \) the minimum \( \min(s, t) \), we have

\[
\sum_{n=0}^{\tau_0} f\left(\frac{Z_n}{m}\right) - f(\rho^*)\tau_0
\]

\[
= \sum_{k \geq 1} \sum_{n = T_{k-1} \land \tau_0}^{T_k \land \tau_0 - 1} \left( f\left(\frac{Z_n}{m}\right) - f(\rho^*) \right) + \sum_{k \geq 1} \sum_{n = T_k^* \land \tau_0}^{T_k \land \tau_0 - 1} \left( f\left(\frac{Z_n}{m}\right) - f(\rho^*) \right).
\]

We bound next the absolute value as follows:

\[
\left| \sum_{n=0}^{\tau_0} f\left(\frac{Z_n}{m}\right) - f(\rho^*)\tau_0 \right| \leq 2f(1) \sum_{k \geq 1} (T_k^* \land \tau_0 - T_{k-1} \land \tau_0) + \varepsilon \tau_0.
\]

It remains to deal with the sum. We define, for \( n \geq 0 \),

\[
K(n) = \max\{k \geq 1: T_{k-1} < n\},
\]
and the sum becomes
\[ \sum_{k \geq 1} (T_k^* \land \tau_0 - T_{k-1} \land \tau_0) = \sum_{k=1}^{K(\tau_0)} (T_k^* \land \tau_0 - T_{k-1}). \]

Let \( \eta > 0 \). We set \( t^\eta_m = \exp(m(V(\rho^*, 0) + \eta)) \).

We decompose the sum as follows:
\[ K(\tau_0) \sum_{k=1}^{K(\tau_0)} (T_k^* \land \tau_0 - T_{k-1}). \leq \tau_0 \leq t^\eta_m K(\tau_0) \sum_{k=1}^{K(\tau_0)} (T_k^* \land \tau_0 - T_{k-1}). \]

We suppose that the process starts from \( i \in \{1, \ldots, m\} \). The estimates are carried out exactly in the same way for any value of \( i \), therefore, to alleviate the notation, we remove the starting point from the notation. Throughout the proof the expectation \( E \) and the probability \( P \) are meant with respect to the initial condition \( Z_0 = i \). Taking expectation in the previous inequalities, we get
\[ \left| E\left( \sum_{n=0}^{\tau_0} f\left( \frac{Z_n}{m} \right) \right) - f(\rho^*)E(\tau_0) \right| \leq \varepsilon E(\tau_0) + 2f(1)E(1_{\tau_0 > Nj}) + 2f(1)E\left( 1_{\tau_0 \leq t^\eta_m} \sum_{k=1}^{K(\tau_0)} (T_k^* \land \tau_0 - T_{k-1}) \right). \]

Next, we take care of the second term.

**Lemma 7.12.** For any \( N, j \geq 1 \),
\[ E(\tau_0 1_{\tau_0 > Nj}) \leq NjP(\tau_0 > Nj) + \sum_{n \geq N} jP(\tau_0 > n). \]

**Proof.** We compute
\[ E(\tau_0 1_{\tau_0 > Nj}) = \sum_{k > Nj} kP(\tau_0 = k) = \sum_{k > Nj} \sum_{n \geq 0} 1_{n < k}P(\tau_0 = k) \]
\[ = \sum_{n \geq 0} \sum_{k > Nj} P(\tau_0 = k) = \sum_{n \geq 0} P(\tau_0 > \max(Nj, n)) \]
\[ \leq NjP(\tau_0 > Nj) + \sum_{n \geq Nj} P(\tau_0 > n). \]
Next,
\[
\sum_{n \geq N_j} P(\tau_0 > n) = \sum_{n \geq N} \sum_{k=0}^{j-1} P(\tau_0 > n j + k) \leq \sum_{n \geq N} j P(\tau_0 > n j),
\]
and we have the desired inequality. \(\square\)

We apply Lemma 7.6 with \(\varepsilon = \eta/8\): there exists \(j \geq 1\) such that
\[
\forall n \geq 0 \quad P(\tau_0 > n j | Z_0 = m) \leq (1 - \exp(-m V(\rho^*,0) - m \eta/2))^n.
\]
We apply Lemma 7.12 with this \(j\) and
\[
N = \left\lfloor \frac{t^m_n}{j} \right\rfloor = \left\lfloor \frac{1}{j} \exp(m V(\rho^*,0) + m \eta) \right\rfloor,
\]
and we use the previous inequality
\[
E(\tau_0 1_{\tau_0 > t^m_n}) \leq E(\tau_0 1_{\tau_0 > N_j}) \leq N j P(\tau_0 > N_j) + \sum_{n \geq N} j P(\tau_0 > n j)
\]
\[
\leq (N j + j \exp(m V(\rho^*,0) + m \eta/2))(1 - \exp(-m V(\rho^*,0) - m \eta/2))^N
\]
\[
\leq (1 + j \exp(m V(\rho^*,0) + m \eta)) \exp(-N \exp(-m V(\rho^*,0) - m \eta/2)).
\]
Thanks to the choice of \(N\), this last quantity goes to 0 as \(m\) goes to \(\infty\). Thus
\[
\lim_{m \to \infty} E(1_{\tau_0 > t^m_n} \tau_0) = 0.
\]
We deal now with the last sum in the inequality before Lemma 7.12. We give first an upper bound on \(K\).

**Lemma 7.13.** \(\textbf{We suppose that } \sigma e^{-a} > 1. \textbf{There exists } c > 0, \textbf{depending on } \delta, \textbf{such that, asymptotically,}\)
\[
\forall k, n \geq 0 \quad P(K(n) > k) \leq \frac{n^k}{k!} \exp(-cmk).
\]

**Proof.** For \(k \geq 0\), we define
\[
S_k = \sup \left\{ T_k^* \leq n < T_k : \frac{Z_n}{m} \in U(\delta) \right\}.
\]
For \(k, n \geq 0\), we have
\[
P(K(n) > k) = P(T_k < n) = \sum_{t^* \leq s < t < n} P(T_k^* = t^*, S_k = s, T_k = t).
\]
Let \( h \geq 1 \) and \( c > 0 \) be associated to \( \delta \) as in Corollary 7.10. We can suppose that \( h \geq 2 \). For given values of \( t^* \) and \( s \), we split the sum over \( t \) in two parts,

\[
\sum_{t: s < t < n} P(T_k^* = t^*, S_k = s, T_k = t) = \sum_{t: t > s + h + 1} \cdots + \sum_{t: s < t \leq s + h + 1} \cdots.
\]

We study next the first sum, when \( t > s + h + 1 \). We condition on the state at time \( s + 1 \)

\[
\sum_{t: t > s + h + 1} \cdots = \sum_{t: t > s + h + 1, \ j \in mU(2\delta) \setminus mU(\delta)} P(T_k^* = t^*, S_k = s, Z_{s+1} = j, T_k = t)
\]

\[
\leq \sum_{t: t > s + h + 1, \ j \in mU(2\delta) \setminus mU(\delta)} P\left( T_k^* = t^*, Z_{s+1} = j, Z_t \notin mU(2\delta) \middle| Z_{s+1}, \ldots, Z_{t-1} \in mU(2\delta) \setminus mU(\delta) \right)
\]

\[
= \sum_{t: t > s + h + 1, \ j \in mU(2\delta) \setminus mU(\delta)} P(Z_{s+1}, \ldots, Z_{t-1} \in mU(2\delta) \setminus mU(\delta), Z_t \notin mU(2\delta) | Z_{s+1} = j)
\]

\[
\times P(T_k^* = t^*, Z_{s+1} = j).
\]

For \( 0 \leq s < n \) and \( t > s + h + 1 \),

\[
P(Z_{s+1}, \ldots, Z_{t-1} \in mU(2\delta) \setminus mU(\delta), Z_t \notin mU(2\delta) | Z_{s+1} = j)
\]

\[
\leq P\left( m\delta \leq Z_r \leq m(\rho^* - \delta) \right.
\]

\[
\text{for } s + 1 \leq r \leq t - 1 \left| \ Z_{s+1} = j \right.
\]

\[
+ P\left( Z_r \geq m(\rho^* + \delta) \right. 
\]

\[
\text{for } s + 1 \leq r \leq t - 1 \left| \ Z_{s+1} = j \right.
\]

\[
\leq \exp\left( -cm \left\lfloor \frac{t - s - 2}{h} \right\rfloor \right).
\]

In fact, in Corollary 7.10, we gave an upper bound on the first probability. Yet the second probability can be handled in exactly the same way. Thus

\[
\sum_{t: t > s + h + 1} \cdots \leq \left( \sum_{t \geq h + 1} \exp\left( -cm \left\lfloor \frac{t - 1}{h} \right\rfloor \right) \right) P(T_k^* = t^*).
\]

Let us focus on the second sum. We condition on the state at time \( s \)

\[
\sum_{t: s < t \leq s + h + 1} \cdots = \sum_{t: s < t \leq s + h + 1, \ j \in mU(\delta)} P(T_k^* = t^*, S_k = s, Z_a = j, T_k = t)
\]
\[
\begin{align*}
&\leq \sum_{t:s<t\leq s+h+1} P(Z_t \notin mU(2\delta) \mid Z_s = j) P(T_k^* = t^*, Z_s = j) \\
&\leq \sum_{t:1\leq t\leq h+1} P(Z_t \notin mU(2\delta) \mid Z_0 = j) P(T_k^* = t^*, Z_s = j).
\end{align*}
\]

For any \(j \in mU(\delta)\), using the monotonicity of \((Z_n)_{n \geq 0}\),
\[
P(Z_t \notin mU(2\delta) \mid Z_0 = j)
\leq P(Z_t \leq m(\rho^* - 2\delta) \mid Z_0 = j) + P(Z_t \geq m(\rho^* + 2\delta) \mid Z_0 = j)
\leq P(Z_t \leq m(\rho^* - 2\delta) \mid Z_0 = [\lfloor (\rho^* - \delta) m \rfloor])
+ P(Z_t \geq m(\rho^* + 2\delta) \mid Z_0 = [\lfloor (\rho^* + \delta) m \rfloor]).
\]

We use the large deviation principle stated in Corollary 7.3 to estimate the last two terms. For any \(t \in \{1, \ldots, h+1\} \),
\[
\limsup_{\ell,q \to \infty, \ell q \to a} \frac{1}{m} \ln P(Z_t \leq m(\rho^* - 2\delta) \mid Z_0 = [\lfloor (\rho^* - \delta) m \rfloor])
\leq -\inf\{V_t(\rho^* - \delta, \rho) : \rho \leq \rho^* - 2\delta\},
\]
\[
\limsup_{\ell,q \to \infty, \ell q \to a} \frac{1}{m} \ln P(Z_t \geq m(\rho^* + 2\delta) \mid Z_0 = [\lfloor (\rho^* + \delta) m \rfloor])
\leq -\inf\{V_t(\rho^* + \delta, \rho) : \rho \geq \rho^* + 2\delta\}.
\]

By compactness, the infima are realized. Because of the constraints on \(\rho\), the point \(\rho\) realizing the infimum
\[
\inf\{V_t(\rho^* - \delta, \rho) : \rho \leq \rho^* - 2\delta\}
\]
is not an iterate of \(\rho^* - \delta\) through \(F\). Hence by Lemma 7.4, the above infimum is positive. We argue in the same way for the second infimum, and we conclude that there exists \(c' > 0\), depending on \(\delta\), such that, asymptotically,
\[
\forall j \in mU(\delta) \sum_{t:1\leq t\leq h+1} P(Z_t \notin mU(2\delta) \mid Z_0 = j) \leq \exp(-c'm),
\]
whence
\[
\sum_{t:s\leq t\leq s+h+1} \cdots \leq \exp(-c'm) P(T_k^* = t^*).
\]

Let \(c'' > 0\) be such that, asymptotically,
\[
\sum_{t \geq h+1} \exp\left(-cm\left\lfloor \frac{t-1}{h} \right\rfloor \right) + \exp(-c'm) \leq \exp(-c''m).
\]
Reporting in the initial equality, we obtain that, asymptotically, for any \( n, k \geq 0 \),

\[
P(T_k < n) \leq \sum_{t^* \leq s < n} \exp(-c''m)P(T_k^* = t^*)
\]

\[
\leq \sum_{s < n} \exp(-c''m)P(T_k^* \leq s)
\]

\[
\leq \sum_{s < n} \exp(-c''m)P(T_{k-1} < s).
\]

Iterating this inequality, we obtain

\[
P(T_k < n) \leq \sum_{0 \leq n_0 < \cdots < n_{k-1} < n} \exp(-c''mk) \leq \frac{n^k}{k!} \exp(-c''mk)
\]

as required. \( \square \)

We estimate now the last sum in the inequality before Lemma 7.12. By the Cauchy–Schwarz inequality, we have

\[
E\left(1 \leq t_m^0 \leq \sum_{k=1}^{K(t_0)} (T_k^* \wedge \tau_0 - T_{k-1})\right)
\]

\[
= \sum_{k \geq 1} E\left(1 \leq t_m^0, 1 \leq K(t_0) \leq k \mid T_k^* \wedge \tau_0 - T_{k-1}\right)
\]

\[(\bigcirc) \leq \sum_{k \geq 1} P(\tau_0 \leq t_m^0, K(t_0) \geq k)^{1/2} (E(1 \leq k \leq K(t_0) \mid T_k^* \wedge \tau_0 - T_{k-1})^2)^{1/2}
\]

\[
\leq \sum_{k \geq 1} P(K(t_m^0) \geq k)^{1/2} (E(1 \leq k \leq K(t_0) \mid T_k^* \wedge \tau_0 - T_{k-1})^2)^{1/2}.
\]

If \( 1 \leq k \leq K(\tau_0) \), then \( T_{k-1} < \tau_0 \) and \( Z_{T_{k-1}} > 0 \), so that, using the Markov property,

\[
E(1 \leq k \leq K(\tau_0) \mid T_k^* \wedge \tau_0 - T_{k-1})^2)
\]

\[
= \sum_{1 \leq j \leq m} E(1 \leq k \leq K(\tau_0) \mid T_k^* \wedge \tau_0 - T_{k-1})^2 \mid Z_{T_{k-1}} = j) P(Z_{T_{k-1}} = j)
\]

\[
\leq \sum_{1 \leq j \leq m} E((T_1^* \wedge \tau_0)^2 \mid Z_0 = j) P(Z_{T_{k-1}} = j).
\]

We will next bound the time \( T_1^* \wedge \tau_0 \), starting from \( j \in \{1, \ldots, m\} \).
Lemma 7.14. We suppose that \( \sigma e^{-a} > 1 \). For any \( \delta > 0 \), there exists \( c > 0 \), depending on \( \delta \), such that, asymptotically, for \( j \in \{1, \ldots, m\} \),

\[
P(m(\rho^*-\delta) < Z_{[c \ln m]} < m(\rho^*+\delta)|Z_0 = j) \geq \frac{1}{m^{c \ln m}}.
\]

Proof. Using Lemma 7.7, there exists \( c > 0 \) such that, asymptotically,

\[
P(Z_{[c \ln m]} \leq m(\rho^*-\delta)|Z_0 = 1) \leq 1 - \frac{1}{m^{c \ln m}}.
\]

Proceeding as in Lemma 7.9, we obtain that there exist \( h, c' > 0 \) such that, asymptotically,

\[
P(Z_h \geq m(\rho^*+\delta)|Z_0 = m) \leq \exp(-c'm).
\]

We have then

\[
P(Z_{[c \ln m]} \geq m(\rho^*+\delta)|Z_0 = m)
= \sum_{j \in \{1, \ldots, m\}} P(Z_{[c \ln m]} \geq m(\rho^*+\delta), Z_{[c \ln m]} - h = j|Z_0 = m)
= \sum_{j \in \{1, \ldots, m\}} P(Z_h \geq m(\rho^*+\delta)|Z_0 = j)P(Z_{[c \ln m]} - h = j|Z_0 = m)
\leq \exp(-c'm).
\]

Using the monotonicity of \((Z_n)_{n \geq 0}\), we have

\[
P(Z_{[c \ln m]} \notin m(\rho^*-\delta), m(\rho^*+\delta)|Z_0 = j)
\leq P(Z_{[c \ln m]} \leq m(\rho^*-\delta)|Z_0 = j) + P(Z_{[c \ln m]} \geq m(\rho^*+\delta)|Z_0 = j)
\leq P(Z_{[c \ln m]} \leq m(\rho^*-\delta)|Z_0 = j) + P(Z_{[c \ln m]} \geq m(\rho^*+\delta)|Z_0 = m)
\leq 1 - \frac{1}{m^{c \ln m}} + \exp(-c'm).
\]

This estimate is uniform with respect to \( j \in \{1, \ldots, m\} \). \( \square \)

Corollary 7.15. We suppose that \( \sigma e^{-a} > 1 \). For any \( \delta > 0 \), there exists \( c > 0 \), depending on \( \delta \), such that, asymptotically, for \( j \in \{1, \ldots, m\} \),

\[
\forall n \geq 0 \quad P(T_1^* \wedge \tau_0 \geq n[c \ln m]|Z_0 = j) \leq \left(1 - \frac{1}{m^{c \ln m}}\right)^n.
\]

Proof. We proceed as in Corollary 7.10 to obtain this inequality. We divide the interval \( \{0, \ldots, n[c \ln m]\} \) into subintervals of length \([c \ln m]\), and we use repeatedly the estimate of Lemma 7.14. \( \square \)
By Corollary 7.15, we have, asymptotically, for any \( j \in \{1, \ldots, m\} \),
\[
E((T_1^* \wedge \tau_0)^2 | Z_0 = j) = \sum_{k \geq 1} P(T_1^* \wedge \tau_0 \geq \sqrt{k} | Z_0 = j)
\leq \sum_{k \geq 1} \left(1 - \frac{1}{m^{c \ln m}}\right)^{\lfloor \sqrt{k}/[|\ln m|] \rfloor}.
\]

Let us set
\[
\alpha = 1 - \frac{1}{m^{c \ln m}}, \quad t = \lfloor c \ln m \rfloor.
\]

We have
\[
\sum_{k \geq 1} \alpha^{\lfloor \sqrt{k}/t \rfloor} \leq \sum_{k \geq 1} \alpha^{\sqrt{k}/t - 1} \leq \int_0^\infty \alpha^{\sqrt{x}/t - 1} dx = \frac{t^2}{\alpha (\ln \alpha)^2} \int_0^\infty e^{-\sqrt{x}} dy,
\]
therefore, asymptotically, for any \( j \in \{1, \ldots, m\} \),
\[
E((T_1^* \wedge \tau_0)^2 | Z_0 = j) \leq m^{3c \ln m}.
\]

Reporting in the inequality before Lemma 7.14, we have
\[
\forall k \geq 1 \quad E(1_{k \leq K(\tau_0)}(T_k^* \wedge \tau_0 - T_{k-1})^2) \leq m^{3c \ln m}.
\]

Plugging this estimate in (○) and using Lemma 7.13, we obtain
\[
E\left(1_{\tau_0 \leq t_m^{\eta}} \sum_{k=1}^{K(\tau_0)} (T_k^* \wedge \tau_0 - T_{k-1}) \right)
\leq \sum_{k \geq 0} (m^{3c \ln m})^{1/2} P(K(\eta_m) > k)^{1/2}
\leq m^{3c \ln m} \left(t_m^{\eta} \exp(-cm/3) + 1 + \sum_{k \geq t_m^{\eta} \exp(-cm/3)} \left(\frac{(t_m^{\eta})^k}{k!} \exp(-cmk)^{1/2}\right)\right)
\leq m^{3c \ln m} \left(t_m^{\eta} \exp(-cm/3) + 1 + \sum_{k \geq 0} \exp\left(\frac{k}{2} - cm\frac{k}{3}\right)\right).
\]

To get the last inequality, we have used that \( k! \geq (k/e)^k \), whence, for \( k \geq t_m^{\eta} \exp(-cm/3) \),
\[
\frac{(t_m^{\eta})^k}{k!} \leq \left(\frac{e^{\eta}}{k}\right)^k \leq \exp(k + cmk/3).
\]
We choose $\eta$ such that $\eta < c/3$. The above inequality implies that
\[
\limsup_{\ell, m \to \infty, q \to 0} \frac{1}{m} \ln E \left( 1_{\tau_0 \leq \ell_m} \sum_{k=1}^{K(\tau_0)} (T_k^* \wedge \tau_0 - T_{k-1}) \right) 
\leq \max \left( V(\rho^*, 0) + \eta - \frac{c}{3}, 0 \right) < V(\rho^*, 0).
\]
All these estimates, together with Proposition 7.5, imply that, asymptotically, uniformly with respect to $i \in \{1, \ldots, m\}$,
\[
\left| E \left( \sum_{n=0}^{\tau_0} f \left( \frac{Z_n}{m} \right) | Z_0 = i \right) - f(\rho^*) E(\tau_0 | Z_0 = i) \right| \leq 3 \varepsilon E(\tau_0 | Z_0 = i).
\]
This achieves the proof of Proposition 7.11. □

8. The neutral phase. We denote by $\mathcal{N}$ the set of the populations which do not contain the master sequence $w^*$, that is,
\[
\mathcal{N} = (A^\ell \setminus \{w^*\})^m.
\]
Since we deal with the sharp peak landscape, the transition mechanism of the process restricted to the set $\mathcal{N}$ is neutral. We consider a Wright–Fisher process $(X_n)_{n \geq 0}$ starting from a population of $\mathcal{N}$. We wish to evaluate the first time when a master sequence appears in the population,
\[
\tau_* = \inf \{ n \geq 0 : X_n \notin \mathcal{N} \}.
\]
We call the time $\tau_*$ the discovery time. Until the time $\tau_*$, the process evolves in $\mathcal{N}$, and the dynamics of the Wright–Fisher model in $\mathcal{N}$ does not depend on $\sigma$. In particular, the law of the discovery time $\tau_*$ is the same for the Wright–Fisher model with $\sigma > 1$ and the neutral Wright–Fisher model with $\sigma = 1$. Therefore, we compute the estimates for the latter model.

Neutral hypothesis. Throughout this section, we suppose that $\sigma = 1$.

8.1. Mutation dynamics. We consider a Markov chain $(Y_n)_{n \geq 0}$ with state space $\{0, \ldots, \ell\}$ and having for transition matrix the lumped mutation matrix $M_H$. In this section, we recall some properties and estimates concerning the Markov chain $(Y_n)_{n \geq 0}$. We refer to the corresponding section of [3] for the detailed proofs. The Markov chain $(Y_n)_{n \geq 0}$ is monotone. We denote by $B$ the binomial law $B(\ell, 1 - 1/\kappa)$ with parameters $\ell$ and $1 - 1/\kappa$, that is,
\[
\forall b \in \{0, \ldots, \ell\} \quad B(b) = \binom{\ell}{b} \left( 1 - \frac{1}{\kappa} \right)^b \left( \frac{1}{\kappa} \right)^{\ell-b}.
\]
The matrix $M_H$ is reversible with respect to the binomial law $B$. This binomial law is the invariant probability measure of the Markov chain $(Y_n)_{n \geq 0}$. When $\ell$ grows, the law $B$ concentrates exponentially fast in a neighborhood of its mean $\ell_\kappa = \ell(1 - 1/\kappa)$. We restate next without proofs several inequalities and estimates proved in [3].

**Lemma 8.1.** For $b \leq \ell/2$, we have

$$\frac{1}{\kappa^\ell} \left( \frac{\ell}{2b} \right)^b \leq B(b) \leq \frac{\ell^b}{\kappa^\ell}. $$

**Proposition 8.2.** We suppose that $\ell \to +\infty, q \to 0, \ell q \to a \in ]0, +\infty[. $ Asymptotically, we have

$$\forall n \geq \sqrt{\ell} \quad P(Y_n \geq \ln \ell|Y_0 = 0) \geq 1 - \exp(-\frac{1}{2}(\ln \ell)^2).$$

**Proposition 8.3.** We suppose that $\ell \to +\infty, q \to 0, \ell q \to a \in ]0, +\infty[. $ Let $\varepsilon \in ]0, 1[. $ There exists $c(\varepsilon) > 0$ such that, asymptotically, we have

$$\forall n \geq \frac{4\ell}{a\varepsilon} \quad P(Y_n \geq \ell_\kappa(1 - \varepsilon)|Y_0 = 0) \geq 1 - \exp(-c(\varepsilon)\ell).$$

We define

$$\tau_0 = \inf\{n \geq 0 : Y_n = 0\}.$$

**Proposition 8.4.** For any $a \in ]0, +\infty[,$

$$\limsup_{\ell \to \infty, q \to 0, \ell q \to a} \frac{1}{\ell} \ln E(\tau_0|Y_0 = \ell) \leq \ln \kappa.$$ 

8.2. **Ancestral lines.** Let us define an ancestral line. For $i \in \{1, \ldots, m\}$ and $n \geq 1$, we denote by $\mathcal{I}(i, n, n - 1)$ the index of the ancestor at time $n - 1$ of the $i$th chromosome at time $n$. More precisely, if the $i$th chromosome of the population at time $n$ has been obtained by replicating the $j$th chromosome of the population at time $n - 1$, then $\mathcal{I}(i, n, n - 1) = j$. For $s \leq n$, the index $\mathcal{I}(i, n, s)$ of the ancestor at time $s$ of the $i$th chromosome at time $n$ is then defined recursively with the help of the following formula:

$$\mathcal{I}(i, n, s) = \mathcal{I}(\mathcal{I}(i, n, n - 1), n - 1, s).$$

We define also $\mathcal{I}(i, n, n) = i$. The ancestor at time $s$ of the $i$th chromosome at time $n$ is the chromosome

$$\text{ancestor}(i, n, s) = X_s(\mathcal{I}(i, n, s)).$$
The ancestral line of the $i$th chromosome at time $n$ is the sequence of its ancestors until time 0,

$$(\text{ancestor}(i,n,s), 0 \leq s \leq n) = (X_s(I(i,n,s)), 0 \leq s \leq n).$$

**Proposition 8.5.** Let $b \in \{0, \ldots, m\}$, and let $(X_n)_{n \geq 0}$ be the neutral Wright–Fisher process starting from $(b)^m$. Let $i \in \{1, \ldots, m\}$. For any $n \geq 0$, the law of the ancestral line $(\text{ancestor}(i,n,s), 0 \leq s \leq n)$ of the $i$th chromosome of $X_n$ is equal to the law of $(Y_0, \ldots, Y_n)$ starting from $b$.

The proof is standard. One can proceed by induction as in [3]. In fact, the ancestral lines of the individuals at time $n$ are given by a coalescent process. Along an ancestral line, a chromosome moves according to the mutation dynamics given by the matrix $M_H$.

**8.3. Discovery time.** The dynamics of the processes $(O_\ell_n)_{n \geq 0}$, $(O_1^1)_{n \geq 0}$ in $\mathcal{N}$ are the same as the original process $(O_n)_{n \geq 0}$. Therefore we can use the original process to compute the discovery time

$$\tau^* = \inf \{n \geq 0 : O_n \in W^*\}.$$

The law of the discovery time $\tau^*$ is the same for the distance process and the occupancy process. With a slight abuse of notation, we let

$$\tau^* = \inf \{n \geq 0 : D_n \in W^*\}.$$

We will carry out the estimates of $\tau^*$ for the distance process $(D_n)_{n \geq 0}$. Notice that the case $\alpha = +\infty$ is not covered by the result of next proposition. This case will be handled separately, with the help of the intermediate inequality of Corollary 8.7.

**Notation.** For $b \in \{0, \ldots, \ell\}$, we denote by $(b)^m$ the vector column whose components are all equal to $b$.

**Proposition 8.6.** Let $a \in [0, +\infty[$ and $\alpha \in [0, +\infty[$. For any $d \in \mathcal{N}$,

$$\lim_{\ell,m \to \infty, q \to 0} \frac{1}{\ell} \ln E(\tau^*|D_0 = d) = \ln \kappa.$$

**Proof.** By Corollary 5.4, the neutral distance process $(D_n)_{n \geq 0}$ is monotone. Therefore, for any $d \in \mathcal{N}$, we have

$$E(\tau^*|D_0 = (1)^m) \leq E(\tau^*|D_0 = d) \leq E(\tau^*|D_0 = (\ell)^m).$$

To bound the discovery time $\tau^*$ from above, we consider the time needed for a single chromosome to discover the master sequence $w^*$, and we remark
that, if the master sequence has not been discovered until time \( n \) in the
distance process, then certainly the ancestral line of any chromosome present
at time \( n \) does not contain the master sequence. By Proposition 8.5, the
ancestral line of any chromosome present at time \( n \) has the same law as
\( Y_0, \ldots, Y_n \). Therefore, we conclude that

\[
\forall n \geq 0 \quad P(\tau^* > n | D_0 = (\ell)^m) \leq P(\tau_0 > n | Y_0 = \ell),
\]

where \( \tau_0 \) is the hitting time of 0 for the process \((Y_n)_{n \geq 0}\). Summing this
inequality over \( n \geq 0 \), we obtain the following upper bound.

**Corollary 8.7.** For any \( d \in \mathcal{N} \), any \( m \geq 1 \), we have

\[
E(\tau^* | D_0 = d) \leq E(\tau_0 | Y_0 = \ell).
\]

With the help of Proposition 8.4, we obtain the desired upper bound. To
bound the discovery time \( \tau^* \) from below, we use the same strategy as in
[3]. There are two main differences in the case of the Wright–Fisher model.
First the time scale is multiplied by \( m \), because \( m \) mutations can occur at
each generation. Second, the neutral distance process \((D_n)_{n \geq 0}\) has positive
correlations. This makes the proof substantially simpler than in the case of
the Moran model, where a technical exponential estimate had to be used
instead of a correlation inequality. We give here only the main steps of the
proof. The details are similar to [3] in that they involve repeated intermediate
conditionings, use of the Markov property and monotonicity.

We suppose that the distance process starts from \((1)^m\), and we will estimate
the probability of a specific scenario leading to a discovery time close
to \( \kappa \ell \). Let \( \mathcal{E} \) be the event

\[
\mathcal{E} = \{ \forall n \leq \ell^{3/4}, \forall i \in \{1, \ldots, m\}, U_{n}^{i,1} > q/(\kappa - 1) \}.
\]

If the event \( \mathcal{E} \) occurs, then, until time \( \ell^{3/4} \), none of the mutation events in
the process \((D_n)_{n \geq 0}\) can create a master sequence. Let \( \varepsilon > 0 \). Conditioning
on the population at time \( m\ell^{3/4} \), we obtain

\[
P(\tau^* > \kappa^{\ell(1-\varepsilon)} | D_0 = (1)^m)
\geq P(\tau^* > \kappa^{\ell(1-\varepsilon)}, \mathcal{E} | D_0 = (1)^m)
\geq P(\tau^* > \kappa^{\ell(1-\varepsilon)} | D_0 = (\ln \ell)^m) P(D_{\ell^{3/4}} \geq (\ln \ell)^m, \mathcal{E} | D_0 = (1)^m).
\]

We first study the last term in the above inequality. The status of the process
at time \( \ell^{3/4} \) is a function of the random matrices

\[
R_n = (S_n^i, U_{n,1}^{i,1}, \ldots, U_{n,\ell}^{i} )_{1 \leq i \leq m}, \quad 1 \leq n \leq \ell^{3/4}.
\]
We make an intermediate conditioning with respect to the variables $S^i_n$,
\[
P(D_{\ell^3/4} \geq (\ln \ell)^m, \mathcal{E}|D_0 = (1)^m) = E(P(D_{\ell^3/4} \geq (\ln \ell)^m, \mathcal{E}|S^i_n, 1 \leq i \leq m, 1 \leq n \leq \ell^{3/4}|D_0 = (1)^m).
\]
The variables $S^i_n, 1 \leq i \leq m, 1 \leq n \leq \ell^{3/4}$ being fixed, all the indices of the chromosomes selected for replication are fixed, and since the mutation map $\mathcal{M}_H(:, u_1, \ldots, u_\ell)$ is nondecreasing with respect to $u_1, \ldots, u_\ell$, the state of the process at time $\ell^{3/4}$ is a nondecreasing function of the variables $U^i_n, 1 \leq i \leq m, 1 \leq n \leq \ell^{3/4}$.

Thus the events $\mathcal{E}$ and $D_{\ell^3/4} \geq (\ln \ell)^m$ are both nondecreasing with respect to these variables. By the FKG inequality for a product measure,
\[
P(D_{\ell^3/4} \geq (\ln \ell)^m, \mathcal{E}|S^i_n, 1 \leq i \leq m, 1 \leq n \leq \ell^{3/4}) \geq P(D_{\ell^3/4} \geq (\ln \ell)^m|S^i_n, 1 \leq i \leq m, 1 \leq n \leq \ell^{3/4})P(\mathcal{E}).
\]
We have used the fact that $\mathcal{E}$ does not depend on the variables $S^i_n$. Reporting in the conditioning, we obtain
\[
P(D_{\ell^3/4} \geq (\ln \ell)^m, \mathcal{E}) \geq P(D_{\ell^3/4} \geq (\ln \ell)^m)P(\mathcal{E}).
\]
By Proposition 5.8, the distance process starting from $(1)^m$ has positive correlations, therefore
\[
P(D_{\ell^3/4} \geq (\ln \ell)^m) \geq \prod_{1 \leq i \leq m} P(D_{\ell^3/4}(i) \geq \ln \ell) = P(Y_{\ell^3/4} \geq \ln \ell)^m.
\]
Using the estimate of Proposition 8.2, we get
\[
P(D_{\ell^3/4} \geq (\ln \ell)^m, \mathcal{E}) \geq \left(1 - \exp\left(-\frac{1}{2}(\ln \ell)^2\right)\right)^m \left(1 - \frac{q}{\kappa - 1}\right)^{m\ell^{3/4}}.
\]
We study next
\[
P(\tau^* > \kappa^{\ell(1-\varepsilon)}|D_0 = (\ln \ell)^m).
\]
The following inequality can be proved exactly as Lemma 10.15 of [3].

**Lemma 8.8.** For $b \in \{1, \ldots, \ell\}$, we have
\[
\forall n \geq 0 \quad P(\tau^* \leq n|D_0 = (b)^m) \leq nm \frac{B(0)}{B(b)}.
\]
Let \( \varepsilon' > 0 \). Conditioning on the population at time \( \ell^2 \), we obtain

\[
P(\tau^* > \kappa^{(1-\varepsilon)}|D_0 = (\ln \ell)^m)
\]

\[
\geq P(\tau^* > \kappa^{(1-\varepsilon)}|D_0 = (\ell_{\kappa}(1-\varepsilon'))^m)
\]

\[
\times P(\tau^* > \ell^2, D_{\ell^2} \geq (\ell_{\kappa}(1-\varepsilon'))^m|D_0 = (\ln \ell)^m).
\]

We first take care of the last probability. We write

\[
P(\tau^* > \ell^2, D_{\ell^2} \geq (\ell_{\kappa}(1-\varepsilon'))^m|D_0 = (\ln \ell)^m)
\]

\[
\geq P(\ell_{\kappa}(1-\varepsilon'))^m|D_0 = (\ln \ell)^m) - P(\tau^* \leq \ell^2|D_0 = (\ln \ell)^m).
\]

To control the last term, we use the inequality of Lemma 8.8 with \( n = \ell^2 \) and \( b = \ln \ell \), and Lemma 8.1,

\[
P(\tau^* \leq \ell^2|D_0 = (\ln \ell)^m) \leq \ell^2 m \frac{\mathcal{B}(0)}{\mathcal{B}(\ln \ell)} \leq \ell^2 m \left( \frac{2 \ln \ell}{\ell} \right)^{\ln \ell}.
\]

For the other term, we use the monotonicity of the process \( (D_n)_{n \geq 0} \), the fact that it has positive correlations (by Proposition 5.8), and Proposition 8.3 to get

\[
P(\tau^* \leq \ell^2|D_0 = (\ln \ell)^m)
\]

\[
\geq \prod_{1 \leq i \leq m} P(\ell_{\kappa}(1-\varepsilon'))^m|D_0 = (0)^m
\]

\[
= P(Y_{\ell^2} \geq \ell_{\kappa}(1-\varepsilon'|Y_0 = 0)^m \geq (1 - \exp(-c(\varepsilon')\ell))^m.
\]

Plugging the inequalities (b) and (z) into the inequality (z), we obtain

\[
P(\tau^* > \ell^2, D_{\ell^2} \geq (\ell_{\kappa}(1-\varepsilon'))^m|D_0 = (\ln \ell)^m)
\]

\[
\geq (1 - \exp(-c(\varepsilon')\ell))^m - \ell^2 m \left( \frac{2 \ln \ell}{\ell} \right)^{\ln \ell}.
\]

Using Lemma 8.8 with \( n = \kappa^{(1-\varepsilon)} \) and \( b = \ell_{\kappa}(1-\varepsilon') \), and a standard large deviation estimates, we see that, for \( \varepsilon' \) small enough, there exists \( c(\varepsilon) > 0 \) such that, for \( \ell \) large enough,

\[
P(\tau^* \leq \kappa^{(1-\varepsilon)}|D_0 = (\ell_{\kappa}(1-\varepsilon'))^m) \leq \frac{\kappa^{(1-\varepsilon)} m \mathcal{B}(0)}{\mathcal{B}(\ell_{\kappa}(1-\varepsilon'))} \leq me^{-c(\varepsilon)\ell}.
\]

Plugging the estimates (♠) and (♠) into the inequality (♥), we conclude that, for \( \ell \) large enough,

\[
P(\tau^* > \kappa^{(1-\varepsilon)}|D_0 = (1)^m)
\]

\[
\geq \left( 1 - \exp\left( -\frac{1}{2} (\ln \ell)^2 \right) \right)^m \left( 1 - \frac{q}{\kappa - 1} \right)^{m\ell^{3/4}}
\]
\[ \times (1 - m \exp(-c(\varepsilon)\ell))(1 - \exp(-c(\varepsilon')\ell))^m - \ell^2 m \left( \frac{2 \ln \ell}{\ell} \right)^{\ln \ell} \].

Moreover, by Markov’s inequality,
\[ E(\tau^*|D_0 = (1)^m) \geq \kappa^{\ell(1-\varepsilon)} P(\tau^* \geq \kappa^{\ell(1-\varepsilon)}|D_0 = (1)^m). \]

It follows that
\[ \liminf_{\ell,m \to \infty, q \to 0} \frac{1}{\ell} \ln E(\tau^*|D_0 = (1)^m) \geq (1 - \varepsilon) \ln \kappa. \]

Letting \( \varepsilon \) go to 0 yields the desired lower bound. \( \square \)

**9. Synthesis.** As in Theorem 3.1, we suppose that \( \ell \to +\infty, m \to +\infty, q \to 0 \), in such a way that \( \ell q \to a \in ]0, +\infty[ \), \( m/\ell \to \alpha \in ]0, +\infty[ \). We put now together the estimates of Sections 7 and 8 in order to evaluate the formula for the invariant measure obtained at the end of Section 6.3. Using the monotonicity of \((Z_n^\theta)_{n \geq 0}\), we have
\[ E(\tau_0|Z_0^\theta = 1) \leq \sum_{i=1}^{m} E(\tau_0|Z_0^\theta = i) P(O^\theta_{\tau^*}(0) = i|O_0^\theta = o^{\theta}_{\text{exit}}) \]
\[ \leq E(\tau_0|Z_0^\theta = m). \]

These inequalities and Proposition 7.5 imply that
\[ \lim_{\ell,m \to \infty, q \to 0} \frac{1}{m} \ln \sum_{i=1}^{m} E(\tau_0|Z_0^\theta = i) P(O^\theta_{\tau^*}(0) = i|O_0^\theta = o^{\theta}_{\text{exit}}) = V(\rho^*(a), 0). \]

By Proposition 8.6, for \( \alpha \in ]0, +\infty[ \),
\[ \lim_{\ell,m \to \infty, q \to 0} \frac{1}{\ell} \ln E(\tau^*|O_0^\theta = o^{\theta}_{\text{exit}}) = \ln \kappa. \]

For the case \( \alpha = +\infty \), by Corollary 8.7 and Proposition 8.4,
\[ \limsup_{\ell,m \to \infty, q \to 0} \frac{1}{\ell} \ln E(\tau^*|O_0^\theta = o^{\theta}_{\text{exit}}) \leq \ln \kappa. \]

These estimates allow us to evaluate the ratio between the discovery time and the persistence time. We define a function \( \psi : ]0, +\infty[ \to ]0, +\infty[ \) by setting
\[ \forall a \in ]0, +\infty[, \psi(a) = V(\rho^*(a), 0). \]
For $\alpha \in [0, +\infty]$ or $\alpha = +\infty$, we have

$$\lim_{\ell, m \to \infty, q \to 0, \ell q \to a, (m/\ell) \to \alpha} \frac{\sum_{i=1}^{m} E(\tau_0 | Z_0^\theta = i) P(O_0^\theta, (0) = i | O_0^\theta = \theta) }{E(\tau^* | O_0^\theta = \theta) } = \begin{cases} 0, & \text{if } \alpha \psi(a) < \ln \kappa, \\ +\infty, & \text{if } \alpha \psi(a) > \ln \kappa. \end{cases}$$

By Proposition 7.11, we have

$$\lim_{\ell, m \to \infty, q \to 0} \sum_{i=1}^{m} E(\sum_{n=0}^{\infty} f(Z_n^\theta / m) | Z_0^\theta = i) P(O_0^\theta, (0) = i | O_0^\theta = \theta) = f(\rho^*) \int_{[0,1]} f d\nu,$$

Putting together the bounds on $\nu$ given in Section 6.3 and the previous considerations, we conclude that

$$\lim_{\ell, m \to \infty, q \to 0, \ell q \to a, (m/\ell) \to \alpha} \int_{[0,1]} f d\nu = \begin{cases} 0, & \text{if } \alpha \psi(a) < \ln \kappa, \\ f(\rho^*(a)), & \text{if } \alpha \psi(a) > \ln \kappa. \end{cases}$$

This is valid for any continuous nondecreasing function $f : [0, 1] \to \mathbb{R}$ such that $f(0) = 0$.
