Abstract
In this study, we investigated that the activated carbon (AC)-based supercapacitor and introduced SIFSIX-3-Ni as a porous conducting additive to increase its electrochemical performances of AC/SIFSIX-3-Ni composite-based supercapacitor. The AC/SIFSIX-3-Ni composites are coated onto the aluminum substrate using the doctor blade method and conducted an ion-gel electrolyte to produce a symmetrical supercapacitor. The electrochemical properties of the AC/SIFSIX-3-Ni composite-based supercapacitor are evaluated through cyclic voltammetry (CV), electrochemical impedance spectroscopy (EIS), and galvanostatic charge/discharge tests (GCD). The AC/SIFSIX-3-Ni composite-based supercapacitor showed reasonable capacitive behavior in various electrochemical measurements, including CV, EIS, and GCD. The highest specific capacitance of the AC/SIFSIX-3-Ni composite-based supercapacitor was 129 F g⁻¹ at 20 mV s⁻¹.

1 Introduction
As the demand for energy to replace fossil fuels has increased, the energy storage devices have begun to attract attention [1, 2]. Due to these demands, many studies are still struggling to increase the energy and power density of energy storage devices, including batteries, fuel cells, and supercapacitors (SCs) [3, 4]. SCs are promising devices compared to batteries and fuel cells [5]. SCs have high power density, chemical stability, and cycle life of more than 10,000 cycles [4]. SCs are also desired for various applications, such as electric vehicles, portable devices, and wearable electronics [6]. There are two types of SCs, depending on the charge/discharge mechanism. The first is the electrochemical double-layer capacitor (EDLC), which is worked by the electric double layer that is formed at the electrode/electrolyte surface [7, 8]. As the electrode material for EDLC, carbon materials with a large surface area, such as graphene, activated carbon, and carbon nanotubes, are mainly conducted [1, 9–12]. The second type is a pseudocapacitor, where electric charges are stored by the faradaic reaction. The pseudocapacitor mostly uses the transition metal oxides, conducting polymer and metal–organic frameworks (MOFs) for the electrode materials [1, 6, 7, 13, 14].

In an effort to improve the EDLC, carbon-based electrodes have played an important role. Several nanostructured carbons, including graphene, carbon nanotubes, carbon nanofibers, have been studied, but activated carbon is preferred due to its low cost for production and environmental reasons [15]. Activated carbon can be prepared through physical/chemical processes with baobab fruit shell, coir pith, cucumis melo fruit peel, teakwood sawdust, and it is possible to fabricate electrode of energy storage devices with low cost [16–19]. Nevertheless, AC has been limited to the absorption/desorption process due to its complex pore structure. Several methods have been reported to overcome this problem by developing hybrid materials [20, 21].

MOFs are porous materials for redox reaction and have a crystal structure by metal ions and organic linker [14, 22]. MOFs are a promising candidate for SCs due to their large surface area and adjustable pore size [23, 24]. Various studies have been denoted to improve the stability and specific capacitance of MOF materials in the
application of supercapacitor [25–27]. However, MOFs have two disadvantages: low electrical conductivity and poor chemical/physical stability [28]. Many researchers have attempted to increase the electrochemical properties by combining SIFSIX-3-Ni with carbon materials [29]. For example, CNF/SIFSIX-3-Ni composites as asymmetric supercapacitors exhibit a high specific capacitance 164.5 F g⁻¹ [13]. Another effective way is to reduce the particle size of the MOFs material in nanometers that can reduce the ion diffusion distance of the electrolyte. Liu reported the fabrication of hierarchical porous nickel-based SIFSIX-3-Ni, and the supercapacitor has high real specific capacitance 87 F g⁻¹ [30].

Electrolyte affects the core characteristics of supercapacitors, and not only determine the driving voltage range but also includes output, internal resistance, charge/discharge velocity, driving temperature, cycle stability, self-discharge, and toxicity [31]. Generally, carbon electrodes, separators, and liquid electrolytes are introduced and conducted to prepare a conventional capacitor. These mentioned materials for conventional capacitors can be caused by leakage, ignition problems by liquid types of electrolytes. The gel electrolyte can solve problems, such as leakage, ignition, which are problems that occur in liquid electrolytes [32]. In this regard, the stability of gel electrolytes is higher than that of liquid electrolytes [33, 34]. For example, for a supercapacitor made of gel polymer electrolytes prepared with a mass ratio of PVA/glycerol/NaCl 1:1:0.8 and an AC(activated carbon) electrode has an ionic conductivity value of 62.3 mS cm⁻¹ and a capacitance value of 211 F g⁻¹ [34].

In this study, we fabricated a porous structured symmetric supercapacitor by utilizing the large surface area of SIFSIX-3-Ni and AC. For preparation of a solid-state supercapacitor, we used ion-gel electrolyte and AC/SIFSIX-3-Ni-based electrode was coated by inexpensive doctor blade coating method. The maximum specific capacitance of real supercapacitor was 129 F g⁻¹ and a high power density of 1940 W kg⁻¹ at a scan rate of 20 mV s⁻¹.

2 Experimental

2.1 Materials

PVA(Polyvinyl alcohol), EC(Ethylene carbonate), BMIMBF₄(1-Butyl-3-methylimidazolium tetrafluoroborate) were purchased from Sigma Aldrich, and KI was purchased from Junsei Chemical Co., Ltd to produce solid-state ion gel as an electrolyte. Ni(NO₃)₂·6H₂O (≥ 97%, nickel(II) nitrate hexahydrate), (NH₄)₂SiF₆ (≥ 98%, ammonium hexafluorosilicate), pyrazine (99%), and methanol (≥ 98%) were obtained from Sigma Aldrich to synthesis the SIFSIX-3-Ni. NMP(N-methyl-2-pyrrolidone), was obtained from Sigma Aldrich, AC(Activated carbon) was purchased from Kansai Coke and Chemicals Co. Ltd, Super-P(Carbon black) was obtained from Imerys Graphite and Carbon, CMC(Carboxymethyl cellulose) was sourced from Tokyo Chemical Industry Co., Ltd, and BM-400B was obtained from ZEON corporation to prepare electrode.

2.2 Synthesis of SIFSIX-3-Ni metal–organic framework

SIFSIX-3-Ni was synthesized by the modification of the procedure from the previous report [28]. Briefly, Ni(NO₃)₂·6H₂O (0.87 g, 3 mmol), (NH₄)₂SiF₆ (0.53 g, 3 mmol), and pyrazine (0.48 g, 6 mmol) were dissolved in water (4 mL). The reaction was allowed by heating at 60 °C for 48 h under gentle agitation. The blue-color precipitates were collected by simple filtration, and then the acquired powders were rinsed by storing it in 40 mL of anhydrous methanol for 1 day. Thereafter, the resultant was further purified by a combination of sonication and centrifugation method with rinsing with extra anhydrous methanol. The blue color precipitates were collected by simple filtration, and then the acquired powders were rinsed by storing it in 40 mL of anhydrous methanol for 1 day. Thereafter, the resultant was further purified by a combination of sonication and centrifugation method with rinsing with extra anhydrous methanol. The purification step was repeated 5 times. The obtained results were dried at 120 °C for 12 h under reduced pressure.

2.3 Preparation of ion-gel electrolyte

To prepare ion-gel electrolytes, PVA (1.8 g) was dissolved in distilled water at 90 °C for 2 h. Then, KI (3.78 g) was slowly added into the PVA solution and mixed for an hour.

| Table 1 | Electrochemical properties of the AC/SIFSIX-3-Ni composite-based supercapacitor |
|---------|---------------------------------|
| Sample  | $R_s$(Ohm) | $R_I$(Ohm) | Specific capacitance (F/g) | Energy density (W/kg) | Power density (Wh/kg) |
| AC/SIFSIX-3-Ni-0 | 9.5 | 0.7 | 28 | 8 | 420 |
| AC/SIFSIX-3-Ni-0.5 | 3 | 0.2 | 129 | 40 | 1940 |
| AC/SIFSIX-3-Ni-1.0 | 7 | 0.4 | 107 | 33 | 1618 |
| AC/SIFSIX-3-Ni-1.5 | 8 | 0.5 | 87 | 27 | 1318 |
After that, EC (6.3 g) was dissolved in PVA/KI solution for an hour. Finally, BMIMBF4 (0.57 g) was mixed until being a homogeneous state to create ion gel as a solid-state electrolyte.

2.4 Fabrication of AC/SIFSIX-3-Ni composite slurry

All processes for fabricating AC/SIFSIX-3-Ni composite materials were mixed by Thinky Mixer at 2000 rpm. CMC was dispersed in NMP for 5 min. Then, SIFSIX-3-Ni (0.005 g) was added into the NMP/CMC solution and dispersed for 5 min. After that, Super-P (0.1625 g) was added into the above solution and stirred for 10 min. Afterwards, AC (0.995 g) was added into the solution and mixed for 13 min. Finally, BM-400B (0.125 g) was added to the solution and dispersed for 5 min. The as-prepared sample was denoted as AC/SIFSIX-3-Ni-X, and X stands for the weight percentage of SIFSIX-3-Ni. The weight percentage of SIFSIX-3-Ni in the composite was 0, 0.5, 1.0, and 1.5, and each sample was named as AC/SIFSIX-3-Ni-0, AC/SIFSIX-3-Ni-0.5, AC/SIFSIX-3-Ni-1.0, and AC/SIFSIX-3-Ni-1.5, respectively.

2.5 Fabrication of AC/SIFSIX-3-Ni electrodes

To fabricate AC/SIFSIX-3-Ni composite-based electrodes, the aluminum substrate was cut with a length of 5 cm and a width of 1 cm. After cutting the substrate, AC/SIFSIX-3-Ni composite slurry was coated onto the aluminum substrate by a doctor blade method with respect to the variation of SIFSIX-3-Ni wt% in the composite. The AC/SIFSIX-3-Ni composite-based electrodes were dried at 200 °C in the oven for an hour to remove residual solvent.

2.6 Preparation of AC/SIFSIX-3-Ni composite-based supercapacitor

The AC/SIFSIX-3-Ni composite-based supercapacitor was fabricated by assembling the AC/SIFSIX-3-Ni composite electrodes and ion-gel as a solid-state electrolyte in a sandwich conformation. The ion-gel electrolyte was heated to 40 °C to activate ion in the solution, and then the fabricated AC/SIFSIX-3-Ni composite electrodes were soaked in the electrolyte solution for 10 min to diffuse electrolyte into the AC/SIFSIX-3-Ni composite. After then, the electrodes were placed into a fume hood for 30 min to remove the moisture. Two such AC/SIFSIX-3-Ni composite electrodes with ion-gel electrolytes were face to face in a sandwich configuration. The prepared full device as a supercapacitor was dried at room temperature for an hour to remove residual solvent and moisture.

3 Characterization

3.1 XRD

Powder X-ray diffraction (PXRD) was carried out at room temperature on a D/Max 2500/PC (Rigaku) using Cu-Kα radiation (λ = 1.5418 Å), 2θ scans between 5° and 50° with a step size of 0.02° were performed for a duration of 45 min.

3.2 FT-IR

Fourier-transform infrared spectroscopy (FT-IR, Perkin) was conducted in the range of 4000–400 cm⁻¹ at RT.

3.3 SEM

Scanning electron microscopy (SEM) images of SIFSIX-3-Ni, AC, Super-P and electrode were obtained using a XL30-SFEG. The accelerating voltage was 20.0 kV and the emission current 88 µA.

3.4 Cyclic voltammetry

Cyclic voltammetry (CV) measurements were performed at room temperature with a two-electrode system using a ZIVE SP2 electrochemical workstation (ZIVE-LAB). CV measurements were recorded over the scan rate at 20 mV s⁻¹ with a potential window of—0.5 to 1 V. The specific capacitance (Csp) of symmetric supercapacitor was calculated from the CV curves [34].

\[ C = \frac{\int I dV}{2 \times v \times m \times \Delta V} \]  

In this equation, m is the mass of active material, v is the scan rate, \( \Delta V \) represents the high and low potential limit of the CV measurement, and I is the constant current. Energy density and power density were driven by Eq. (2), Eq. (3) [34]. In those equations, C is the specific capacitance, V represents the difference between a low potential and a high potential window and v is the sweep time.

\[ E = \frac{1}{2} C V^2 \]  
\[ P = \frac{E}{v} \]  

3.4.1 Electrochemical impedance spectroscopy (EIS)

Electrochemical impedance spectroscopy (EIS) was used to inquire about the electrochemical behavior at the
3.4.2 Charge and discharge measurement

Galvanostatic charge/discharge tests of the AC/SIFSIX-3-Ni composite-based supercapacitor were performed using a battery test system (ZIVE-LAB) between 0 and 1 V with a constant current density as 0.5 A g\(^{-1}\). Capacitance retention was measured by 3000 charge/discharge cycle.

4 Results and discussion

4.1 Physical properties of the SIFSIX-3-Ni

SIFSIX-3-Ni was synthesized by the conventional solution reaction method to apply for the reinforcing additive to the supercapacitor electrode. The acquired SIFSIX-3-Ni resultant was characterized by powder XRD to determine its typical crystal structure in comparison with its crystallographically defined simulation pattern (Fig. 1a). The XRD pattern of SIFSIX-3-Ni showed that a strong peak at 12.7° is well consistent with its simulated XRD pattern, as well as other typical peaks derived from SIFSIX-3-Ni were also well matched with the simulated one. FT-IR spectrum of SIFSIX-3-Ni also evidenced its successful synthesis (Fig. 1b). The characteristic peaks at ca. 3118/3065 cm\(^{-1}\) and ca. 1435/1127/1070 cm\(^{-1}\) are derived from the –CH aromatic bonds and –CN– bonds in the pyrazine ligands. The strong peak, which corresponded to octahedral SiF\(_6\)\(^{2-}\), was also observed at ca. 834 and 773 cm\(^{-1}\). As such, those well support that SIFSIX-3-Ni was well synthesized.

The SEM images of SIFSIX-3-Ni and AC/SIFSIX-3-Ni-0.5 electrode are shown in Fig. 2. SIFSIX-3-Ni had cube form and united structure (Fig. 2a). Super-P had a particle that was enough to allow electricity to pass evenly to the electrode (Fig. 2b). AC was a porous structure, a resonable feature that could more effectively support the electron transfer process (Fig. 2c). Figure 2d showed that super-p was well dispersed on the surface of the activated carbon.

4.2 Electrochemical properties of the SIFSIX-3-Ni-based supercapacitor

Cyclic Voltammetry (CV) was used to investigate electrochemical behavior under different weight percentages of SIFSIX-3-Ni. Figure 3a showed the CV curve of AC/SIFSIX-3-Ni composite-based supercapacitor at different weight percentages in the potential window of -0.5 V ~ 1 V. The AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor exhibited and quasi-rectangular shape with widest current rather than other weight percentages of SIFSIX-3-Ni. As the weight percentage of SIFSIX-3-Ni was increased to 0.5 wt%, the active sites of AC might have been occupied by SIFSIX-3-Ni, which led to a higher \(C_{sp}\) value [35]. However, when the weight percentage of the SIFSIX-3-Ni was greater than 0.5wt%, excess SIFSIX-3-Ni would decrease the electric conductivity, which led to a smaller \(C_{sp}\) value [35]. According to this result, the SIFSIX-3-Ni, which a porous additive material, could enhance electrochemical property by adding to the AC-based supercapacitor and acting as a role to porous additive material in the electrode [25]. In Fig. 3b, the Nyquist plot showed that all of the AC/SIFSIX-3-Ni composite-based supercapacitors gave a semicircle at a high-frequency region, followed by a straight line at the low-frequency region. The semicircle represented the electron transfer rate at the interface of the electrode/electrolyte, which is denoted as charge transfer resistance (\(R_{ct}\)) [35]. In comparing the contents of AC/SIFSIX-3-Ni, it was obvious that the \(R_{ct}\) value for AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor was smaller than that of other contents of SIFSIX-3-Ni-based supercapacitors. The straight slope
in the low-frequency region represented the ion diffusion from the electrolyte to the electrode surface. The Nyquist plot of AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor showed better electrochemical charge transport properties. The internal resistance value of the AC/SIFSIX-3-0.5 composite-based supercapacitor was 3.0 Ω, while the AC/SIFSIX-3-Ni-1.5 composite-based supercapacitor showed 8.1 Ω (Fig. 3b). The result also explained that the optimized SIFSIX-3-Ni contents could be maintained the electric conductivity and improved electrochemical performance [29]. Figure 3c showed the charge/discharge curves of AC/SIFSIX-3-Ni composite-based supercapacitor at 0.5 A g\(^{-1}\) of constant current density. The AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor showed also symmetric charge/discharge graph, the smallest IR drop and the longest discharge time which indicated that the enhanced electrochemical properties of the AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor. This result also corresponded to CV and EIS data.

The cyclic stability of the AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor was evaluated by galvanostatic charge/discharge for 3000 cycles. The specific capacitance of the AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor was 98 F g\(^{-1}\) after 3000 charge/discharge cycles, which decreased about 20% from the initial specific capacitance indicating the robustness of the AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor (Fig. 4a). The overall electrochemical performance showed that AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor exhibited a higher specific capacitance (129 F g\(^{-1}\)) compared to other contents of the AC/SIFSIX-3-Ni composite-based supercapacitor (Fig. 4b). The remarkable improvement of the electrochemical performance was attributed to the optimized amount of the SIFSIX-3-Ni in the AC/SIFSIX-3-Ni. It is noted that SIFSIX-3-Ni could provide the extra pseudo-capacitance, which also increased the specific capacitance of the AC/SIFSIX-3-Ni composite-based supercapacitor [36]. The energy and power density were also calculated to evaluate the electrochemical behavior of the AC/SIFSIX-3-Ni composite-based supercapacitor [37]. The AC/SIFSIX-3-Ni-0.5 composite-based supercapacitor showed a high energy density of 40 Wh kg\(^{-1}\) at a power density of 1940 W kg\(^{-1}\) (Fig. 4c). The results were much higher than that previously reported systems, including Co2-SIFSIX-3-Ni [2], N, S, and O tri-doping AC [5], CoNi MOF nanosheet/nanotube [8], Ni/SWCNT [13], and NiCo-MOF/acetylene black-based supercapacitors [29]. It suggested that our work is a promising candidate for future energy storage devices and able to scale up to industry. All the analyzed electrochemical performances data can be found in Table 1.

5 Conclusion

The all-solid-state AC/SIFSIX-3-Ni composite-based supercapacitor was successfully assembled, which gave enhanced electrochemical performance by optimizing of the SIFSIX-3-Ni weight percentage in composite. The specific

capacitance value of the AC/SIFSIX-3-Ni composite-based supercapacitor showed 129 F g\(^{-1}\) at the scan rate 20 mV s\(^{-1}\). The fabricated supercapacitor also maintained 80% of its initial capacitance value even after 3000 charge/discharge cycles. There are still limitations to carry out optimal electrochemical performances, including capacitance value and energy density of the supercapacitor. To achieve and overcome this issue, electrode materials ionic liquid- and/or organic salt-based electrolytes should be further investigated to improve capacitance and energy density.
