We propose a nonlinear Schrödinger equation in a Hilbert space enlarged with an ancilla such that the partial trace of its solution obeys to the Lindblad equation of an open quantum system. The dynamics involved by this nonlinear Schrödinger equation constitutes then a purification of the Lindbladian dynamics. This nonlinear equation is compared with other Schrödinger like equations appearing in the theory of open systems. We study the (non adiabatic) geometric phases involved by this purification and show that our theory unifies several definitions of geometric phases for open systems which have been previously proposed. We study the geometry involved by this purification and show that it is a complicated geometric structure related to an higher gauge theory, i.e. a categorical bibundle with a connective structure.

CONTENTS

I. Introduction

II. Purification process
   A. The purification bundle and the stratification
   B. The $C^*$-module structure
   C. $C^*$-adjointness

III. Purification of Lindblad dynamics
   A. The nonlinear Schrödinger equation of the purified dynamics
      1. From the Lindblad equation to the nonlinear Schrödinger equation
      2. From the nonlinear Schrödinger equation to the Lindblad equation
      3. Comparison with other Schrödinger equations associated with the open quantum systems
      4. Example: control of a two-level system with dephasing and spontaneous emission
   B. Geometric phases of open quantum systems
      1. The different notions of operator valued phases
      2. Operator valued geometric phases
      3. Special cases of left geometric phases
      4. Example: control of a two-level system with dephasing and spontaneous emission

IV. Geometry of mixed states
   A. The geometry as a stratified principal composite bibundle
      1. Regular strata
      2. Singular strata
   B. The geometry as categorical principal bundles
      1. Left principal categorical bundle
      2. Right principal categorical bundle
   C. Connections
      1. The connective structure of the left principal categorical bundle
      2. The connective structure of the right principal categorical bundle

V. Conclusion

\textsuperscript{a)}Electronic mail: david.viennot@utinam.cnrs.fr
Quantum information\textsuperscript{4} and open quantum systems\textsuperscript{2} are subjects of particular interest in the modern physics, dealing with decoherence processes, quantum computation and communication, entanglement processes, distillation protocols, Schmidt decomposition, Markovian and non-Markovian effects, etc. A particular interesting subject in quantum information is the process of purification which consists for a mixed state $\rho$ of the Hilbert space $H_S$ to find a pure state $\Psi \in H_S \otimes H_A$ in an enlarged Hilbert space such that $\rho = \text{tr}_{H_A} |\Psi\rangle \langle \Psi|$. The auxiliary Hilbert space $H_A$ can be viewed as describing an effective environment. In this paper, we want to study the purification process with respect to the dynamics of mixed states. When the dynamics is conservative, i.e. when it is described by a Liouville-von Neumann equation $\dot{\rho} = [H_S, \rho]$ (no relaxation effect occurs), the dynamics of the purification and the related mathematical structures have been extensively studied, see for example ref.\textsuperscript{4,5}. We study in this paper the case where the environment of the quantum system induces relaxation effects, with a the dynamics obeying to a Lindblad equation\textsuperscript{2}. We will show that the purified state obeys in the enlarged Hilbert space to a nonlinear Schrödinger equation. The emergence of a nonlinearity is not a new phenomenon in the relation between dynamics of mixed and pure states. In ref.\textsuperscript{5} it is shown that the pure dynamics closest to the Lindblad dynamics (in the sense that this pure dynamics is viewed as the dynamics of some tangent vectors on the density matrix manifold) is nonlinear; and in ref.\textsuperscript{2}, a purification protocol needed a nonlinear operation has been proposed (a purification protocol is a set of operations and measurements transforming a mixed state $\rho$ to a pure state $\psi$ of the same Hilbert space without the trace operation – in fact the state $\psi$ depends only on the protocol and is independent from the initial mixed state $\rho$ –, it is a question different from the purification process discussed in the present paper). Moreover the Liouville equation for a piecewise deterministic process is associated for its deterministic part with a nonlinear Schrödinger equation but which does not take into account the jump part (see ref.\textsuperscript{2} chapter 6.1) in contrast with our equation for the purified dynamics.

Geometrization of physical theories is a great active area in theoretical physics. In nonrelativistic quantum dynamics, it is in particular related to the theory of geometric phases (so-called Berry phases). As shown by Simon\textsuperscript{9}, the dynamics of pure states and the Berry phases take place in a geometric structure which is a principal fibre bundle endowed with a connection. Some generalisations of geometric phases have been proposed for mixed states: Uhlmann\textsuperscript{10–12} has proposed a concept of geometric phases based on the theory of transition propabilities for pair of mixed states, the involved geometric structures have been analysed in ref.\textsuperscript{4,13–15}; Sjöqvist etal\textsuperscript{16–17} have proposed a concept of geometric phase based on an interferometric theory, the involved geometric structures have been analysed in ref.\textsuperscript{4,18}; and we have proposed a concept of geometric phase in the adiabatic limit based on the generalisation of the geometric structure studied by Simon from vector bundles to $C^*$-modules\textsuperscript{19–20}. By using the equation of the purified dynamics, we will built a general theory of geometric phases for open quantum systems which unifies these previous approaches. The dynamics of the density matrices present different geometric phases appearing at different levels. This is due to a more complicated gauge structure called higher gauge theory in the litterature\textsuperscript{21–25}. We will show that this structure is a generalization in the category theory of the principal bundle structure, complicated by the stratified structure of the density matrix manifold.

This paper is organized as follows. Section II is devoted to the geometry associated with the purification process by recalling the stratified structure of the density matrix manifold and by introducing some representations of the purified states with the associated inner products. This section introduces some mathematical tools needed to the understanding of the following. Section III shows that the purified state satisfies a nonlinear Schrödinger equation if the associated mixed state satisfies a Lindblad equation. A general theory of geometric phases for open quantum systems is discussed, and there relations with the different propositions of geometric phases are analysed. An example consisting to a two level system driven by an external field and submitted to dephasing and spontaneous emission effects is discussed with a numerical integration of the nonlinear Schrödinger equation and numerical calculations of geometric phases. Section IV studies the geometric structure involved by the general geometric phase theory and the purification process, firstly from the point of view of the ordinary differential geometry, secondly from the point of view of the category theory. It concludes by the introduction of the connective structure and the physical interpretations of the different fields involved by the connection.

\textbf{A note about the notations used here:}

\textit{We adopt the Einstein’s convention: a bottom-top repetition of an index induces a summation.} $\mathcal{B}(H)$ denotes the set of the bounded linear operators of the Hilbert space $H$. For an operator $A \in \mathcal{B}(H)$, $\text{Ran}A$, $\ker A$ and $\text{Sp}(A)$ denotes its range, kernel and spectrum. $\forall A,B \in \mathcal{B}(H)$, we denote the commutator and the anticommutator by $[A,B] = AB - BA$ and $\{A,B\} = AB + BA$. $\text{Aut}_g$, with $g$ a vector space or an algebra, denotes the set of the automorphisms of $g$.

The symbol $\cong$ between two spaces (resp. manifolds) denotes that they are isomorphic (resp. homeomorphic). The symbol $\approx$ between two manifolds denotes that they are locally homeomorphic. The symbol $\Rightarrow$ denotes an
inclusion of $A$ into $B$. $G \times H$ denotes a semi-direct product between two groups $G$ and $H$; $g \triangleright h$ denotes a semi-direct sum between two algebras $g$ and $h$.

$\Pr_1 : V_1 \times V_2 \times \ldots \times V_n \rightarrow V_i$, with $V_i$ some sets, denotes the canonical projection $\Pr_1(x_1, x_2, \ldots, x_n) = x_i$. Let $M$ be a manifold, $T_xM$ denotes its tangent space at $x$ ($TM$ denotes its tangent bundle) and $\Omega^n(M, g)$ denotes its space of $g$-valued differential n-forms. Let $f : M \rightarrow N$ be a diffeomorphism between two manifolds, $f_* : TM \rightarrow TN$ denotes its tangent map (its push-forward) and $f^* : \Omega^* N \rightarrow \Omega^* M$ denotes its cotangent map (its pull-back). Let $E \xrightarrow{\pi} M$ be a fibre bundle ($E$ and $M$ are manifolds and $\pi$ is a surjective map); $\Gamma(M, E)$ denotes the set of its local sections.

For a category $\mathcal{C}$, $\text{Obj} \mathcal{C}$ denotes its collection of objects and $\text{Morph} \mathcal{C}$ denotes its collection of arrows (morphisms). $\forall \in \text{Obj} \mathcal{C}$, $\text{id}_o$ denotes the trivial arrow from and to $o$ (the identity map of $o$). $\forall a \in \text{Morph} \mathcal{C}$, $s(a)$ denotes the source of $a$, and $t(a)$ denotes the target of $a$. $\text{Funct}(\mathcal{C}, \mathcal{C}')$ denotes the set of functors from $\mathcal{C}$ to $\mathcal{C}'$ ($\text{EndFunct}(\mathcal{C}) \equiv \text{Funct}(\mathcal{C}, \mathcal{C})$).

$\forall A(t) \in \mathcal{B}(\mathcal{H}), \quad T e^{-\int_0^t A(a(t)) dt} = U_A(t, t_0)$ denotes the time-ordered exponential (the Dyson series) i.e. the solution of the equation: $\frac{dU_A(t, t_0)}{dt} = -A(t)U_A(t, t_0)$ (with $U_A(t_0, t_0) = \text{id}_\mathcal{H}$). $T e^{-\int_0^t A(a(t)) dt} = V_A(t_0, t)$ denotes the time-antiordered exponential, i.e. the solution of the equation: $\frac{dV_A(t_0, t)}{dt} = -V_A(t_0, t)A(t)$ (with $V_A(t_0, t_0) = \text{id}_\mathcal{H}$).

II. PURIFICATION PROCESS

A. The purification bundle and the stratification

Let $\mathcal{H}_S$ be the Hilbert space of the studied system $S$ (for the sake of simplicity we suppose that $\mathcal{H}_S$ is finite dimensional, $\mathcal{H}_S \simeq \mathbb{C}^n$). Mixed states of $S$ are represented by density operators; the space of density operators being

$$D_0(\mathcal{H}_S) = \{ \rho \in \mathcal{B}(\mathcal{H}_S), \rho^\dagger = \rho, \rho \geq 0, \text{tr}\rho = 1 \} \quad (1)$$

where $\mathcal{B}(\mathcal{H}_S) \simeq \mathfrak{M}_{n \times n}(\mathbb{C})$ denotes the space of linear operators of $\mathcal{H}_S$. The mixed state $\omega_\rho : \mathcal{B}(\mathcal{H}_S) \rightarrow \mathbb{C}$ associated with $\rho \in D_0(\mathcal{H}_S)$ is defined by

$$\forall A \in \mathcal{B}(\mathcal{H}_S), \quad \omega_\rho(A) = \text{tr}(\rho A) \quad (2)$$

$\mathcal{B}(\mathcal{H}_S)$ being a $C^*$-algebra and $\omega_\rho$ being a state of this $C^*$-algebra (see ref.20). In some cases, we can also consider non-normalized density operators:

$$D(\mathcal{H}_S) = \{ \rho \in \mathcal{B}(\mathcal{H}_S), \rho^\dagger = \rho, \rho \geq 0 \} \quad (3)$$

$$\forall A \in \mathcal{B}(\mathcal{H}_S), \quad \omega_\rho(A) = \frac{\text{tr}(\rho A)}{\text{tr}\rho} \quad (4)$$

A purification of a density operator $\rho \in D(\mathcal{H}_S)$ is a state $\Psi_\rho \in \mathcal{H}_S \otimes \mathcal{H}_A$ such that

$$\rho = \text{tr}_{\mathcal{H}_A}[\Psi_\rho] \langle \Psi_\rho | \quad (5)$$

where $\mathcal{H}_A$ is an arbitrary auxiliary Hilbert space called the ancilla and $\langle . | \rangle$ denotes the inner product of $\mathcal{H}_S \otimes \mathcal{H}_A$ induced by the tensor product (tr$_{\mathcal{H}_A}$ denotes the partial trace over $\mathcal{H}_A$). Because of the Schmidt theorem, one needs $	ext{dim} \mathcal{H}_A \geq \text{dim} \mathcal{H}_S$. In order to avoid any unnecessary complication, we choose $\text{dim} \mathcal{H}_A = \text{dim} \mathcal{H}_S$ throughout this paper.

An interesting choice of ancilla consists to the algebraic dual of $\mathcal{H}_S$, $\mathcal{H}_A = \mathcal{H}_S^* = \{ | \psi \rangle \langle \psi | \in \mathcal{H}_S \}$ (the space of continuous linear functionals of $\mathcal{H}_S$). In that case $\mathcal{H}_S \otimes \mathcal{H}_A = \mathcal{H}_S \otimes \mathcal{H}_S^* = \mathcal{B}(\mathcal{H}_S)$. This choice is called standard purification. $\mathcal{B}(\mathcal{H}_S)$ is endowed with the Hilbert-Schmidt inner product:

$$\forall W, Z \in \mathcal{B}(\mathcal{H}_S), \quad (Z | W)_{HS} = \text{tr}_{\mathcal{H}_S}(Z^\dagger W) = \sum_{i=0}^{\infty} W^\alpha W^{\alpha} \quad (6)$$

where $W = W^{\alpha} | \zeta_\alpha \rangle \langle \zeta_\alpha |, (\zeta_\alpha)_{i=1,\ldots,n}$ being an orthonormal basis of $\mathcal{H}_S$. We have then

$$\pi_{HS} : \mathcal{B}(\mathcal{H}_S) \rightarrow D(\mathcal{H}_S) \quad W \mapsto WW^\dagger \quad (7)$$
The restriction of $\pi_{DH}$ on $S_{DH}B(H_S) = \{W \in B(H_S), \|W\|_{DH} = \text{tr}_{HS}(W^† W) = 1\}$ has its values in $D_0(H_S)$. $\pi_{DH}$ is a surjective map.

$$\forall W \in S_{DH}B(H_S), \forall U \in U(H_S), \quad \tilde{W} = WU \Rightarrow \pi_{DH}(\tilde{W}) = WUU^† W = \pi_{DH}(W)$$

(8)

$U(H_S) \cong U(n)$ denotes the group of unitary operators of $H_S$. The action of $U(H_S)$ on $S_{DH}B(H_S)$ is not transitive except for the restriction on the faithful operators (det $W \neq 0$).

$U(H_S)$ acts also on the left of $S_{DH}B(H_S)$. This action induces the adjoint action of the group on $D_0(H_S)$:

$$\forall W \in S_{DH}B(H_S), \forall U \in U(H_S), \quad \tilde{W} = UW \Rightarrow \pi_{DH}(\tilde{W}) = U\pi_{DH}(W)U^† = \pi_{DH}(W)U^{-1}$$

(9)

$\forall \rho \in D_0(H_S)$, the orbit of the density operator $U(H_S)\rho = \{U\rho U^†, U \in U(H_S)\}$ is constituted by all operators which are isospectral to $\rho$. $\Sigma(H_S) = D_0(H_S)/U(H_S) \simeq \Sigma(n)$ where

$$\Sigma(n) = \{(p_1, ..., p_n) \in [0, 1]^n, p_1 \leq p_{i+1}, \sum_{i=1}^n p_i = 1\}$$

(10)

is the $(n-1)$-simplex of the possible eigenvalues (dim $\Sigma(n)$ = $n - 1$). $\Sigma(H_S)$ is the set of diagonal density operators with sorted eigenvalues. Let $\pi_D : D_0(H_S) \rightarrow \Sigma(H_S)$ be the canonical projection associated with the quotient space $D_0(H_S)/U(H_S)$.

$$\forall \sigma \in \Sigma(H_S), \quad \pi_D^{-1}(\sigma) = \{U\sigma U^{-1}, U \in U(H_S)\} \simeq U(H_S)/U(H_S)_{\sigma}$$

(11)

where $U(H_S)_{\sigma} = \{U \in U(H_S), U\sigma U^{-1} = \sigma\}$ is the isotropy subgroup (the stabilizer) of $\sigma$. The bundle $D_0(H_S) \xrightarrow{\pi_D} \Sigma(H_S)$ is not locally trivial, it is a stratified space. A stratum $\Sigma^i(H_S)$ of $\Sigma(H_S)$ is characterized by the degeneracy profil of the eigenvalues. If $\sigma \in \Sigma^i(H_S)$ has $k_1$ eigenvalues with degeneracy equal to $q_1$, $k_2$ eigenvalues with degeneracy equal to $q_2$, etc, then its stabilizer is $U(H_S)_{\sigma} \cong U(q_1)^{k_1} \times ... \times U(q_l)^{k_l}$ (the products are the group direct products) and then $\pi_D^{-1}(\sigma) \cong U(n)/(U(q_1)^{k_1} \times ... \times U(q_l)^{k_l})$. The stratum $\Sigma^n(H_S)$ with no eigenvalue degeneracy is associated with the normalized $U(H_S)_{\sigma} \cong T^n$ (the n-torus) and $\forall \sigma \in \Sigma^0(H_S)$, $\pi_D^{-1}(\sigma) \simeq U(n)/T^n = Fl(n, C)$ (the flag manifold); in the other cases, the fibers of the strata in $D_0(H_S)$ are homeomorphic to partial flag manifolds as Grassmanian manifolds $Gr_p(\mathbb{C}^n) = U(n)/(U(n - p) \times U(p))$, projective manifolds $\mathbb{CP}^{n-1} = U(n)/(U(n-1) \times U(1))$, etc. We distinguish between the regular strata such that det $\rho \neq 0$ (no zero eigenvalue) and the singular strata such that det $\rho = 0$. We remark the presence of two particular strata associated with vertices of $\Sigma(n)$, the singular stratum of the pure states $\Sigma^0(H_S)$ ($p_1 = ... = p_{n-1} = 0$ and $p_n = 1$, $\pi_D^{-1}(\sigma) \simeq U(n)/(U(n-1) \times U(1)) = \mathbb{CP}^{n-1}$), and the regular stratum of the microcanonical state $\Sigma^\infty(H_S)$ ($p_1 = ... = p_n = \frac{1}{n}$, $\pi_D^{-1}(\sigma) \simeq U(n)/U(n) = \{1\}$). Fig. 1 illustrates the stratification for the smallest dimensional cases.
TABLE I. Descriptions of the stratification of the simplex $\Sigma(n)$.

| $n$ | strata $\Sigma'(n)$ | sub-simplices | fiber $\pi_{\Sigma'}(\sigma)$ |
|-----|---------------------|---------------|-----------------------------|
| 2   | $0 < p_1 < p_2$    | edge          | $Fl(2, \mathbb{C})$         |
|     | $p_1 = p_2 = 1/2$  | vertex        | $\{1\}$                    |
|     | $p_1 = 0 < p_2 = 1$| vertex        | $\mathbb{C}P^1$            |
| 3   | $0 < p_1 < p_2 < p_3$| facet        | $Fl(3, \mathbb{C})$         |
|     | $0 < p_1 = p_2 < p_3$| edges       | $\mathbb{C}P^2$            |
|     | $0 < p_1 < p_2 = p_3$| edges       | $\mathbb{C}P^2$            |
|     | $p_1 = 0 < p_2 = p_3 = 1/2$| vertex | $\{1\}$                    |
|     | $p_1 = p_2 = 0 < p_3 = 1$| vertex       | $\mathbb{C}P^2$            |
|     | $p_1 = p_2 = p_3 = 1/3$| vertex       | $\{1\}$                    |
| 4   | $0 < p_1 < p_2 < p_3 < p_4$| cell    | $Fl(4, \mathbb{C})$         |
|     | $0 < p_1 = p_2 < p_3 < p_4$| facets  | $U(4)/(U(2) \times T^2)$   |
|     | $0 < p_1 < p_2 < p_3 = p_4$| facets  | $U(4)/(U(2) \times T^2)$   |
|     | $0 < p_1 < p_2 < p_3 < p_4$| facets  | $U(4)/(U(2) \times T^2)$   |
|     | $0 < p_1 = p_2 < p_3 < p_4$| edges   | $\mathbb{C}P^3$            |
|     | $0 < p_1 < p_2 < p_3 < p_4$| edges   | $\mathbb{C}P^3$            |
|     | $p_1 = 0 < p_2 = p_3 < p_4$| edges   | $\mathbb{C}P^3$            |
|     | $p_1 = 0 < p_2 < p_3 < p_4$| edges   | $\mathbb{C}P^3$            |
|     | $p_1 = 0 < p_2 < p_3 = p_4$| edges   | $\mathbb{C}P^3$            |
|     | $p_1 = 0 < p_2 = p_3 < p_4$| edges   | $\mathbb{C}P^3$            |
|     | $p_1 = p_2 = 0 < p_3 < p_4$| edges   | $\mathbb{C}P^3$            |
|     | $p_1 = p_2 = p_3 = 0 < p_4 = 1$| vertex  | $Gr_2(\mathbb{C}i)$        |
|     | $p_1 = 0 < p_2 = p_3 = p_4 = 1/3$| vertex  | $Gr_2(\mathbb{C}i)$        |
|     | $p_1 = p_2 = 0 < p_3 = p_4 = 1/2$| vertex  | $Gr_2(\mathbb{C}i)$        |
|     | $p_1 = p_2 = p_3 = p_4 = 1/2$| vertex  | $Gr_2(\mathbb{C}i)$        |

Let $\mathcal{H}_A$ be an arbitrary ancilla, and let $(\zeta_i)_{i=1,...,n}$ and $(\xi_\alpha)_{\alpha=1,...,n}$ be orthonormal basis of $\mathcal{H}_S$ and $\mathcal{H}_A$. Let $\Psi : B(\mathcal{H}_S) \xrightarrow{\sim} \mathcal{H}_S \otimes \mathcal{H}_A$ be the (non canonical) isomorphism defined by

$$\forall W \in B(\mathcal{H}_S), \quad \Psi(W) = W^{\alpha_i} \zeta_i \otimes \xi_\alpha \quad (12)$$

with $W = W^{\alpha_i} (\zeta_i) (\xi_\alpha)$. The restriction of $\Psi$ on $S_{HS} B(\mathcal{H}_S)$ has its values in $S(\mathcal{H}_S \otimes \mathcal{H}_A) = \{\Psi \in \mathcal{H}_S \otimes \mathcal{H}_A, ||\Psi||_{\mathcal{H}_S \otimes \mathcal{H}_A} = 1\} \simeq S^{2n^2-1}$ (the $(2n^2 - 1)$-dimensional sphere). Note that $\langle \Psi(Z) \mid \Psi(W) \rangle = \langle Z \mid W \rangle_{HS}$.

The following commutative diagram summarizes the bundle of purification:

$$S_{HS} B(\mathcal{H}_S) \xrightarrow{\sim} S(\mathcal{H}_S \otimes \mathcal{H}_A) \xrightarrow{\sim} S^{2n^2-1}$$

where $\rightarrow$ denotes inclusion maps and $\sim$ denotes homeomorphisms, the vertical arrows are projections.

The ancilla plays the role of an effective environment with which the system is entangled. The right action of $U(\mathcal{H}_S)$ on $S_{HS} B(\mathcal{H}_S)$ is associated with unitary transformations of $\mathcal{H}_A$.

$$\forall U \in U(\mathcal{H}_S), \forall W \in S_{HS} B(\mathcal{H}_S), \quad \Psi(WU) = 1_{\mathcal{H}_S} \otimes U^T \Psi(W) \Rightarrow \pi_{\Sigma'}(\Psi(WU)) = \rho_W \quad (13)$$

where $U^T = (\zeta_\alpha | U \xi_\alpha) (\xi_\beta | (\Psi(W))$ (T denotes the transposition) and $\rho_W = \pi_{\Sigma'}(\Psi(W)) = \pi_{\Sigma'}(W) = WW^T$.

Such a transformation has no consequence for the observar which has only information concerning the system.
(information concerning the environment is lost by the partial trace \( \text{tr}_{H_A} \)). It is then associated with an inobservable reconfiguration of the ancilla (the effective environment). In contrast, the left action of \( U(H_S) \) on \( S_{HS}B(H_S) \) is associated with unitary transformations of \( H_S \) modifying the mixed state:

\[
\forall U \in U(H_S), \forall W \in S_{HS}B(H_S), \quad \Psi(UW) = U \otimes 1_{H_A} \Psi(W) \Rightarrow \pi_\Psi(\Psi(UW)) = U \rho_W U^{-1}
\]  

(14)

In quantum information, it can be interesting to consider also SLOCC transformations (Stochastic Local Operations and Classical Communication). By virtue of the principle of the quantum open systems, information concerning the ancilla (the environment) is lost, the physicist cannot perform SLOCC transformations on \( H_A \). The group of SLOCC transformations on \( H_S \) is \( SL(H_S) \approx SL(n, \mathbb{C}) \) (the group of invertible operators of \( H_S \) with determinant equal to 1). Since \( U(H_S) \supset SU(H_S) \subset SL(H_S) \) \( (SU(H_S) \) is the group of unitary operators of \( H_S \) with determinant equal to 1), the group of unitary and SLOCC transformations are \( SL(H_S) \times U(1) = GL(H_S) \) \( (U(1) \) is the group of phase changes and \( GL(H_S) \) is the group of invertible operators of \( H_S \)).

\[
\forall U \in GL(H_S), \forall W \in B(H_S), \quad \Psi(UW) = U \otimes 1_{H_A} \Psi(W) \Rightarrow \pi_\Psi(\Psi(UW)) = U \rho_W U^\dagger
\]  

(15)

by noting that \( S_{HS}B(H_S) \) and \( D_0(H_S) \) are not stable by the right action of \( SL(H_S) \) (we must then consider \( B(H_S) \) and \( D(H_S) \)). We extend \( \pi_D \) on the whole of \( D(H_S) \) by \( \forall U \in SL(H_S), \forall \rho \in D_0(H_S), \pi_D(U \rho U^\dagger) = \pi_D(\rho) \).

B. The \( C^* \)-module structure

The purification space \( H_S \otimes H_A \) can also be viewed as a left Hilbert \( B(H_S)-C^* \)-module\(^{28}\), the left action of the \( C^* \)-algebra \( B(H_S) \) being defined by

\[
\forall A \in B(H_S), \forall \Psi \in H_S \otimes H_A, \quad A\Psi = A \otimes 1_{H_A} \Psi = \Psi^{\alpha}(A \zeta_\alpha) \otimes \xi_\alpha
\]  

(16)

The inner product of the \( C^* \)-module is defined by

\[
\forall \Psi, \Phi \in H_S \otimes H_A, \quad \langle \Phi | \Psi \rangle_* = \text{tr}_{H_A} | \Psi \rangle \langle \Phi | \in B(H_S)
\]  

(17)

It satisfies the usual properties:

\[
\forall A, B \in B(H_S), \forall \Psi, \Phi, \Xi \in H_S \otimes H_A, \quad \langle \Phi | A \Psi + B \Xi \rangle_* = A \langle \Phi | \Psi \rangle_* + B \langle \Phi | \Xi \rangle_*
\]  

(18)

\[
\forall \Psi, \Phi \in H_S \otimes H_A, \quad \langle \Phi | \Psi \rangle^* = \langle \Psi | \Phi \rangle_*
\]  

(19)

\[
\forall \Psi \in H_S \otimes H_A, \quad \langle \Psi | \Psi \rangle_* \geq 0 \quad \text{and} \quad \langle \Psi | \Psi \rangle_* = 0 \iff \Psi = 0
\]  

(20)

The density operator associated with a state of \( H_S \otimes H_A \) is its square norm with respect to the \( C^* \)-module structure:

\[
\forall \Psi \in H_S \otimes H_A, \quad ||\Psi||^2_* = \langle \Psi | \Psi \rangle_* = \rho_\Psi \in D(H_S)
\]  

(21)

\( B(H_S) \) as the standard purification space is related to the \( C^* \)-module structure by

\[
\forall A \in B(H_S), \forall W \in B(H_S), \quad \Psi(AW) = A\Psi(W)
\]  

(22)

\[
\forall W, Z \in B(H_S), \quad \langle \Psi(W) | \Psi(Z) \rangle_* = ZW^\dagger
\]  

(23)

The right action of \( B(H_S) \) on itself induces a particular class of operators of the \( C^* \)-module acting only on \( H_A \):

\[
\forall A \in B(H_S), \forall W \in B(H_S), \quad \Psi(WA) = 1_{H_S} \otimes A^\dagger \Psi(W)
\]  

(24)

C. \( C^* \)-adjointness

In this part we want to define the adjoint, with respect to the inner product of the \( C^* \)-module, of the right action of \( B(H_S) \) on \( H_S \otimes H_A \).
Definition 1 Let $\Gamma \in \mathcal{B}(\mathcal{H}_S)$. We define $\Gamma^\dagger : \mathcal{H}_S \otimes \mathcal{H}_A \to \mathcal{B}(\mathcal{H}_S)$ by

$$\forall \Psi \in \mathcal{H}_S \otimes \mathcal{H}_A, \quad \Gamma^\dagger(\Psi) = \Gamma_j^i \Psi^{\alpha \beta}(W^*_\Psi)_{\beta i}|\xi_\alpha\rangle\langle \xi_\beta|$$

$$= (W^*_\Psi \Gamma W \Psi)_{\beta i}|\xi_\alpha\rangle\langle \xi_\beta|$$

$$= (W^*_\Psi \Gamma W \Psi)^{\alpha \beta}|\xi_\alpha\rangle\langle \xi_\beta|$$

(25) (26) (27)

where $W_\Psi \in \mathcal{B}(\mathcal{H}_S)$ is such that $\Psi(W_\Psi) = \Psi$, $\Gamma^\dagger = \langle \xi^i|\Gamma \xi_j\rangle$, $\Psi^{\alpha \beta} = W^*_\Psi = \langle \xi^i|W \xi^j\rangle = \langle \xi^i \otimes \xi^j|\Psi\rangle$, and where $W^*_\Psi \in \mathcal{B}(\mathcal{H}_S)$ is the pseudo-inverse of $W_\Psi$:

$$W^*_\Psi W \Psi = 1 - P_{\ker W_\Psi} \text{ and } W_\Psi W^*_\Psi = P_{\text{ran}W_\Psi}$$

where $P_{\ker W_\Psi}$ and $P_{\text{ran}W_\Psi}$ are respectively the projections on the kernel and on the range of $W_\Psi$ in $\mathcal{H}_S$.

Property 1 Let $\Gamma^\dagger(\Psi) = \Gamma^\dagger(\Psi)^\dagger$ (the adjoint $^\dagger$ is in the sense of the inner product of $\mathcal{H}_A$). We have

$$\forall \Phi \in \mathcal{H}_S \otimes \mathcal{H}_A, \quad \langle \Phi|1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Psi\rangle = \langle \Phi|1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Phi\rangle$$

$$\iff \langle \Phi|P_{\text{ran}W_\Psi} \Gamma \otimes 1_{\mathcal{H}_A}\Psi\rangle = \langle \Phi|1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Phi\rangle$$

(29) (30)

For this reason, we call $\Gamma^\dagger$ the $C^*$-adjoint of $\Gamma$.

Corollary 1

$$\forall \Psi \in \mathcal{H}_S \otimes \mathcal{H}_A, \quad 1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Psi = \text{ran}W_\Psi \Gamma \otimes 1_{\mathcal{H}_A}\Psi$$

(31)

Proof:

$$1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Psi = \Gamma^\dagger(\Psi)_{\alpha \beta} \Psi^{\alpha \beta} |\xi_\alpha\rangle \langle \xi_\beta|$$

$$= \Gamma^k_j \Psi^{\alpha \beta}(W^*_\Psi)_{\beta i}|\xi_\alpha\rangle \langle \xi_\beta|$$

$$= \Gamma^k_j \Psi^{\alpha \beta}(W \Psi W^*_\Psi)_{\beta i}|\xi_\alpha\rangle \langle \xi_\beta|$$

$$= (P_{\text{ran}W_\Psi})^j_i \Gamma^k_j \Psi^{\alpha \beta} |\xi_\alpha\rangle \langle \xi_\beta|$$

$$= P_{\text{ran}W_\Psi} \Gamma \otimes 1_{\mathcal{H}_S}|\xi_\alpha\rangle \langle \xi_\beta|$$

(32) (33) (34) (35) (36)

$$\langle \Phi|1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Psi\rangle = \text{tr}_{\mathcal{H}_A}|\Phi\rangle\langle \Phi|1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Psi\rangle$$

$$= \Gamma^\dagger(\Psi)_{\alpha \beta} \Psi^{\alpha \beta} |\xi_\alpha\rangle \langle \xi_\beta|$$

(37) (38)

$$\langle 1_{\mathcal{H}_S} \Gamma^\dagger(\Psi)\Phi|\Psi\rangle = \text{tr}_{\mathcal{H}_A}|\Phi\rangle\langle \Phi|1_{\mathcal{H}_S} \otimes \Gamma^\dagger(\Psi)\Phi\rangle$$

$$= \Psi^{\alpha \beta} \Gamma^\dagger(\Psi)_{\alpha \beta} |\xi_\alpha\rangle \langle \xi_\beta|$$

$$= \Psi^{\alpha \beta} \Gamma^\dagger(\Psi)_{\alpha \beta} |\xi_\alpha\rangle \langle \xi_\beta|$$

(39) (40) (41)

It can be interesting to relate $\text{ran}W_\Psi$ (which appears in the definition of the $C^*$-adjoint) with the density operator.

Property 2 Let $\Psi \in \mathcal{H}_S \otimes \mathcal{H}_A$, $W_\Psi \in \mathcal{B}(\mathcal{H}_S)$ be such that $\Psi(W_\Psi) = \Psi$, and $\rho_\Psi = \|\Psi\|^2 = \pi_\mathcal{A}(\Psi) = W_\Psi W^*_\Psi \in \mathcal{D}(\mathcal{H}_S)$. We have $\text{ran}W_\Psi = \text{ran}\rho_\Psi$ and $\text{coker}W_\Psi = \ker \rho_\Psi$.

Proof: $\ker \rho_\Psi = \{\phi \in \mathcal{H}_S, \Psi^{\alpha \beta} \phi_i = 0\}$. $\phi \in \text{coker}W_\Psi \implies \overline{\phi}_i \Psi^{\alpha \beta} \overline{\Psi}_{ji} = 0 \implies \overline{\phi}_i (\rho_\Psi)^{ij} = 0$ since $\rho_\Psi = \Psi^{\alpha \beta} \overline{\Psi}_{ji} |\xi_\alpha\rangle \langle \xi_\beta|$. We have then $\langle \phi|\rho_\Psi = 0 \implies \rho_\Psi|\phi\rangle = 0 \implies \phi \in \ker \rho_\Psi$. We have then $\ker \rho_\Psi = \ker \rho_\Psi$.

$$(\rho_\Psi)^{ij} |\xi_\alpha\rangle = \Psi^{\alpha \beta} \overline{\Psi}_{ji} |\xi_\alpha\rangle \implies \forall \phi \in \mathcal{H}_S, (\rho_\Psi)^{ij} |\xi_\alpha\rangle = \Psi^{\alpha \beta} \overline{\Psi}_{ji} |\xi_\alpha\rangle$$. We have then $\forall \phi \in \mathcal{H}_S, \rho_\Psi \phi = W_\Psi W^*_\Psi \phi \implies \rho_\Psi \phi \in \text{ran}W_\Psi$. We have then $\text{ran}W_\Psi \subset \text{ran}W_\Psi$.

Suppose that $\xi_\alpha$ is the basis of $\mathcal{H}_S$ is the eigenbasis of $\rho_\Psi$. $\langle \rho_\Psi\rangle^{ij}_\alpha = \Psi^{\alpha \beta} \overline{\Psi}_{ji} = p^i \delta^j$. We can write $\langle \rho_\Psi\rangle^{ij}_\alpha = \rho_\Psi^i \delta^j$. We have then $\rho_\Psi^i = \|\Psi^\dagger\|^2_{\mathcal{H}_A}$. It follows that $\rho_\Psi^i = 0 \implies \rho_\Psi^i = 0 \implies \rho_\Psi^i = 0$. $\forall \alpha$. $\text{ran}W_\Psi = \{\Psi^{\alpha \beta} \phi_i |\xi_\alpha\rangle, \phi \in \mathcal{H}_S\}$ and then $\text{ran}W_\Psi \subset \text{co ran}W_\Psi$. $\text{co ran}W_\Psi = (\ker \rho_\Psi)$). But $\text{co ran}W_\Psi = \text{ran}W_\Psi \cap \text{ran}W_\Psi$. $\text{ran}W_\Psi = \text{ran}W_\Psi$. The two last paragraphs show that $\text{ran}W_\Psi = \text{ran}W_\Psi$. The first one shows that $\text{coker}W_\Psi \subset \ker \rho_\Psi$ but $\text{dim coker}W_\Psi = \text{dim} \text{ran}W_\Psi = \text{dim} \text{ker} \rho_\Psi$ (by definition $\mathcal{H}_S = \text{ran}W_\Psi \oplus \ker W_\Psi$). We have then $\text{dim} \text{coker}W_\Psi = \text{dim} \mathcal{H}_S - \text{dim} \text{ran} \rho_\Psi = \text{dim} \text{ker} \rho_\Psi$ (by virtue of the rank-nullity theorem). This induces that $\ker W_\Psi = \ker \rho_\Psi$. 

$\square$
III. PURIFICATION OF LINDBLAD DYNAMICS

A. The nonlinear Schrödinger equation of the purified dynamics

1. From the Lindblad equation to the nonlinear Schrödinger equation

**Theorem 1** Let \( t \mapsto \rho(t) \in \mathcal{D}(\mathcal{H}_S) \) be a solution of the Lindblad equation

\[
\dot{\rho} = [H_S, \rho] - \frac{i}{2} \gamma^k \{ \Gamma^i_k \Gamma_k, \rho \} + \frac{i}{2} \gamma^k \Gamma_k \rho \Gamma^i_k
\]

(42)

with \( H_S \in \mathcal{B}(\mathcal{H}_S) \) the system Hamiltonian, \( \Gamma_k \in \mathcal{B}(\mathcal{H}_S) \) the quantum jump operators and \( \gamma^k \in [0,1] \) the relaxation rates. Let \( t \mapsto \Psi_\rho(t) \in \mathcal{H}_S \otimes \mathcal{H}_A \) be a purification state of \( \rho(t) \). \( \Psi_\rho \) is solution of the following projected non-hermitian nonlinear Schrödinger equation:

\[
(1_{\mathcal{H}_S} \otimes P_{\text{Ran}\rho}) \dot{\Psi}_\rho = (1_{\mathcal{H}_S} \otimes P_{\text{Ran}\rho}) \left( H_S \otimes 1_{\mathcal{H}_A} \Psi_\rho - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \otimes 1_{\mathcal{H}_A} \Psi_\rho + \frac{i}{2} \gamma^k \Gamma_k \otimes \Gamma^i_k (\Psi_\rho) \Psi_\rho \right)
\]

(43)

**Proof:** Let \( W_\rho(t) \in \mathcal{B}(\mathcal{H}_S) \) be a standard purification of \( \rho \), \( \rho = W_\rho W_\rho^\dagger \), such that \( \Psi(W_\rho) = \Psi_\rho \).

\[
\dot{\rho} = \mathcal{L}(\rho)
\]

(44)

\[
\Rightarrow \dot{W}_\rho W_\rho^\dagger + \dot{W}_\rho^\dagger W_\rho = [H_S, \rho] - \frac{i}{2} \gamma^k \{ \Gamma^i_k \Gamma_k, \rho \} + 2 \times \frac{i}{2} \gamma^k \Gamma_k \rho \Gamma^i_k
\]

(45)

\[
\Rightarrow \dot{W}_\rho W_\rho^\dagger = H_S \rho - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \rho + \frac{i}{2} \gamma^k \Gamma_k \rho \Gamma^i_k - \left( H_S \rho - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \rho + \frac{i}{2} \gamma^k \Gamma_k \rho \Gamma^i_k \right)^\dagger
\]

(46)

\[
\Rightarrow \dot{W}_\rho W_\rho^\dagger = H_S \rho - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \rho + \frac{i}{2} \gamma^k \Gamma_k \rho \Gamma^i_k + K
\]

(47)

where \( K = \Gamma^i_k \) is an arbitrary self-adjoint operator. We can set \( K = 0 \) without loss of generality.

\[
\dot{W}_\rho W_\rho^\dagger = H_S W_\rho W_\rho^\dagger - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k W_\rho W_\rho^\dagger + \frac{i}{2} \gamma^k \Gamma_k W_\rho W_\rho^\dagger \Gamma^i_k
\]

(48)

\[
\Rightarrow \dot{W}_\rho P_{\text{ColRan}\rho} = H_S W_\rho P_{\text{ColRan}\rho} - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k W_\rho P_{\text{ColRan}\rho} + \frac{i}{2} \gamma^k \Gamma_k W_\rho P_{\text{ColRan}\rho} \Gamma^i_k (W_\rho^\dagger)^\ast
\]

(49)

By application of \( \Psi \) on this last equation we find

\[
1_{\mathcal{H}_S} \otimes P_{\text{Ran}\rho} \dot{\Psi}_\rho = H_S \otimes P_{\text{Ran}\rho} \Psi_\rho - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \otimes P_{\text{Ran}\rho} \Psi_\rho + \frac{i}{2} \gamma^k \Gamma_k \otimes (W_\rho^\dagger \Gamma^i_k (W_\rho^\ast)^\ast)^\ast \Psi_\rho
\]

(50)

But \((W_\rho^\dagger \Gamma^i_k (W_\rho^\ast)^\ast)^\ast = (W_\rho^\ast \Gamma_k W_\rho)^\dagger = \Gamma^i_k (\Psi_\rho)\).

On the regular strata, no projection occurs and the purification state is solution of the nonlinear Schrödinger equation:

\[
\dot{\Psi}_\rho = \left( H_S - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \right) \otimes 1_{\mathcal{H}_A} \Psi_\rho + \frac{i}{2} \gamma^k \Gamma_k \otimes \Gamma^i_k (\Psi_\rho) \Psi_\rho
\]

(51)

2. From the nonlinear Schrödinger equation to the Lindblad equation

**Theorem 2** Let \( \Psi \in \mathcal{H}_S \otimes \mathcal{H}_A \) be a solution of the nonlinear Schrödinger equation:

\[
\dot{\Psi} = \left( H_S - \frac{i}{2} \gamma^k \Gamma^i_k \Gamma_k \right) \otimes 1_{\mathcal{H}_A} \Psi + \frac{i}{2} \gamma^k \Gamma_k \otimes \Gamma^i_k (\Psi) \Psi
\]

(52)

Then \( \rho_\Psi = \pi_\mathcal{A}(\Psi) = \| \Psi \|_2^2 \in \mathcal{D}(\mathcal{H}_S) \) is solution of the following master equation:

\[
\dot{\rho}_\Psi = [H_S, \rho_\Psi] - \frac{i}{2} \gamma^k \{ \Gamma^i_k \Gamma_k, \rho_\Psi \} + \frac{i}{2} \gamma^k \{ \Gamma_k \rho_\Psi \Gamma^i_k, P_{\text{Ran}\rho_\Psi} \}
\]

(53)
Proof: Let $H_{\text{eff}}(\bullet) = (H_S - \frac{i}{2} \gamma_k \Gamma_k^\dagger \Gamma_k) \otimes 1_{H_A} + \frac{i}{2} \gamma_k \Gamma_k \otimes \Gamma_k^\dagger(\bullet)$ be the nonlinear operator of the purified dynamics and $P_\Psi = \langle \Psi \rangle \langle \Psi \rangle$. 

\begin{align*}
\text{i}h \dot{\hat{P}}_\Psi &= |\text{i}h\hat{\Psi}\rangle\langle\Psi| - |\Psi\rangle\langle\text{i}h\hat{\Psi}| \\
&= |H_{\text{eff}}(\Psi)\rangle\langle\Psi| - |\Psi\rangle\langle H_{\text{eff}}(\Psi)| \\
&= [H_S \otimes 1_{H_A}, P_\Psi] - \frac{i}{2} \gamma^k \{\Gamma_k^\dagger \Gamma_k \otimes 1_{H_A}, P_\Psi\} + \frac{i}{2} \gamma^k \gamma^j \langle \Gamma_k \otimes \Gamma_j^\dagger \Psi \rangle P_\Psi + \frac{i}{2} \gamma^k \Gamma_k \otimes \Gamma_k^\dagger(\Psi) (56)
\end{align*}

By applying the partial trace $\text{tr}_{H_A}$ on this last equation, we find 

\begin{align*}
\text{i}h \dot{\rho}_\Psi &= [H_S, \rho_\Psi] - \frac{i}{2} \gamma^k \{\Gamma_k^\dagger \Gamma_k, \rho_\Psi\} + \frac{i}{2} \gamma^k \langle \Gamma_k \otimes \Gamma_k^\dagger(\Psi) \rangle_{\Psi} + \frac{i}{2} \gamma^k \gamma^j \langle \Gamma_k \otimes \Gamma_j^\dagger \Psi \rangle_{\Psi} (57)
\end{align*}

Since $\Gamma_k \otimes \Gamma_k^\dagger(\Psi) = (1_{H_S} \otimes \Gamma_k^\dagger(\Psi)) (\Gamma_k \otimes 1_{H_A})$ we have 

\begin{align*}
\text{i}h \dot{\rho}_\Psi &= [H_S, \rho_\Psi] - \frac{i}{2} \gamma^k \{\Gamma_k^\dagger \Gamma_k, \rho_\Psi\} + \frac{i}{2} \gamma^k \langle \Gamma_k \otimes \Gamma_k^\dagger(\Psi) \rangle_{\Psi} + \frac{i}{2} \gamma^k \gamma^j \langle \Gamma_k \otimes \Gamma_j^\dagger \Psi \rangle_{\Psi} (58) \\
&= [H_S, \rho_\Psi] - \frac{i}{2} \gamma^k \{\Gamma_k^\dagger \Gamma_k, \rho_\Psi\} + \frac{i}{2} \gamma^k \{P_{\text{Ran} \rho} \Gamma_k \otimes 1_{H_A}, \Psi \rangle_{\Psi}(59) \\
&= [H_S, \rho_\Psi] - \frac{i}{2} \gamma^k \{\Gamma_k^\dagger \Gamma_k, \rho_\Psi\} + \frac{i}{2} \gamma^k \Gamma_k \rho_\Psi \Gamma_k^\dagger P_{\text{Ran} \rho} + \frac{i}{2} \gamma^k \Gamma_k \rho_\Psi \Gamma_k^\dagger (60)
\end{align*}

On the regular strata, $P_{\text{Ran} \rho} = 1_{H_S}$ and the master equation reduces to the Lindblad equation: 

\begin{align*}
\text{i}h \dot{\rho}_\Psi &= [H_S, \rho_\Psi] - \frac{i}{2} \gamma^k \{\Gamma_k^\dagger \Gamma_k, \rho_\Psi\} + \gamma^k \Gamma_k \rho_\Psi \Gamma_k^\dagger (61)
\end{align*}

3. Comparison with other Schrödinger equations associated with the open quantum systems

We have shown that the purified state obeys on the regular strata to the nonlinear Schrödinger equation: 

\begin{align*}
\text{i}h \dot{\hat{\Psi}}_\rho &= H_{\text{eff}} \otimes 1_{H_A} \hat{\Psi}_\rho + \frac{i}{2} \gamma^k \Gamma_k \otimes \Gamma_k^\dagger(\Psi)_\rho \quad \hat{\Psi}_\rho \in H_S \otimes H_A (62)
\end{align*}

with $H_{\text{eff}} = H_S - \frac{i}{2} \gamma^k \Gamma_k^\dagger \Gamma_k$. Ref.\(^\text{44}\) studies a nonlinear Schrödinger equation for the pure evolution closest to the Lindblad evolution in the sense that it is viewed has the dynamics of some tangent vectors of $D_0(H_S)$. This equation is the following: 

\begin{align*}
\text{i}h \dot{\hat{\Psi}} = (H_{\text{eff}} - \langle H_{\text{eff}} \rangle) \hat{\Psi} + \gamma^k (\Gamma_k^\dagger \psi)(\Gamma_k - (\Gamma_k)\psi) \quad \hat{\Psi} \in H_S (63)
\end{align*}

where $\langle O \rangle_\psi = \langle \psi \rangle_\psi (\forall O \in \mathcal{B}(H_S))$. Except the shift of the operators by their average values, the structure of this equation is similar to eq.\(^\text{42}\). In fact suppose that during a short time the dynamics remains on the singular stratum of the pure states: $\rho = |\psi \rangle \langle \psi |$, in that case $W_\rho = |\psi \rangle_\psi$ and $W_\rho^* = |\psi \rangle_\psi \langle \psi | (\text{with } \psi_0 = \psi (t = 0))$. The equation \(^\text{43}\) becomes then 

\begin{align*}
\text{i}h \dot{\psi} \otimes \psi = (H_{\text{eff}} \psi + \frac{i}{2} \gamma^k (\Gamma_k^\dagger \psi)(\Gamma_k \psi) \otimes \psi (64)
\end{align*}

which is very close to the equation \(^\text{43}\) (except the shift of the operators and a $\frac{1}{2}$ factor).

The deterministic part of the Liouville equation for a piecewise deterministic process is (see ref.\(^\text{44}\) chapter 6.1) $\text{i}h \dot{\psi} = H_{\text{eff}} \psi + \frac{i}{2} \gamma^k (||\Gamma_k \psi||^2) \psi$. Since $||\Gamma_k||^2 = (\Gamma_k^\dagger \Gamma_k)\psi$, it is very close to our equation for a dynamics remaining on the pure state stratum. This is valid only between two quantum jumps; in a same manner equation \(^\text{43}\) could be approximatively valid only during a short time until the quantum jumps described by the operator $\frac{i}{2} \gamma^k (\Gamma_k^\dagger \psi)(\Gamma_k \psi)$ tend to leave the pure state stratum. To describe quantum jumps we add a stochastic process (see ref.\(^\text{44}\)):

\begin{align*}
\text{i}h \text{d}\psi &= H_{\text{eff}} \psi \text{d}t + \frac{i}{2} \gamma^k (\Gamma_k^\dagger \Gamma_k) \psi \text{d}t + i \sqrt{\gamma} dW^k (\Gamma_k - \frac{1}{2} (\Gamma_k^\dagger + \Gamma_k) \psi) \psi \in H_S (65)
\end{align*}

or 

\begin{align*}
\text{i}h \text{d}\psi &= H_{\text{eff}} \psi \text{d}t + \frac{i}{2} \gamma^k (\Gamma_k^\dagger + \Gamma_k) \psi \text{d}t + i \sqrt{\gamma} dW^k (\Gamma_k - \frac{1}{2} (\Gamma_k^\dagger + \Gamma_k) \psi) \psi \in H_S (66)
\end{align*}
TABLE II. Properties of the Schrödinger equations associated with an open quantum system.

| Schrödinger equation | Generator of the quantum jumps | Nature | dim. relation with the density matrix |
|----------------------|--------------------------------|--------|--------------------------------------|
| Hilbert-Schmidt representation | \( \Gamma_k \otimes \Gamma_k^\dagger \) | “superlinear” \(^a\) | \( n^2 \rho = |\Upsilon_\rho \rangle \langle \Upsilon_\rho | \) |
| Purification | \( \frac{i}{\hbar} \gamma^k \Gamma_k \otimes \Gamma_k^\dagger (\Psi_\rho) \) | nonlinear | \( n^2 \rho = \text{tr}_\mathcal{H}_\rho |\Psi_\rho \rangle \langle \Psi_\rho | \) |
| Closest pure evolution | \( \Gamma_k \otimes \Gamma_k^\dagger \) | nonlinear | \( n \text{ tr}(\delta \rho - \delta |\psi \rangle \langle \psi |) \) is minimum \(^b\) |
| Piecewise deterministic process | \( dN_k^t \left( \frac{1}{\hbar} \cdot \hat{S} - 1_{\mathcal{H}_S} \right) \) | nonlinear stochastic | \( n \rho = \mathbb{E}(\langle \psi | \psi \rangle) \) |
| Quantum state diffusion | \( \sqrt{\gamma^k} dW_k^t (\Gamma_k - \hat{S} (\Gamma_k + \Gamma_k^\dagger)) \) | nonlinear stochastic | \( n \rho = \mathbb{E}(\langle \psi | \psi \rangle) \) |

\(^a\) linear in the sense of the superoperator theory

where \( dN_k^t \) is a Poisson process and \( dW_k^t \) is a Wiener process. The first equation is the representation as a piecewise deterministic process and the second one is called quantum state diffusion process. The density matrix is then

\[ \rho = \mathbb{E}(\langle \psi | \psi \rangle) \]

Ref.\(^{11}\) proposes a Schrödinger equation following the dynamics induced by the Lindblad equation:

\[ \hbar \dot{\Upsilon}_\rho = H^{eff} \otimes 1_{\mathcal{H}_A} \Upsilon_\rho - 1_{\mathcal{H}_S} \otimes (H^{eff})^\dagger \Upsilon_\rho + \gamma^k \Gamma_k \otimes \Gamma_k^\dagger \Upsilon_\rho \quad \Upsilon_\rho \in \mathcal{H}_S \otimes \mathcal{H}_A \tag{67} \]

where \( H^{eff} \) is the effective Hamiltonian of the system. Equation (67) is linear, but it is not an equation for the purification, since in this case \( \Upsilon_\rho = \rho \) and \( \text{tr}_\mathcal{H}_\rho |\Psi_\rho \rangle \langle \Psi_\rho | \neq \rho \). In fact, if we choose the \( \mathcal{H}_A = \mathcal{H}_S^* \), equation (67) is precisely the Lindblad equation in the Hilbert-Schmidt representation (in the Liouville space), |\Upsilon_\rho \rangle = \rho_{\mathcal{H}_S} \otimes |\zeta^b | \rangle = \rho \) (equation (67) is then just a reformulation of the “superoperator” formalism).

The comparisons between the different Schrödinger equations associated with an open quantum system are summarized in Table II.

---

**4. Example: control of a two-level system with dephasing and spontaneous emission**

**a. The model:** We consider the two level system governed by the following Lindblad equation

\[ \hbar \dot{\rho} = [H_S, \rho] - \frac{i}{\hbar} \gamma^k \{\Gamma_k \rho, \Gamma_k^\dagger\} + i \gamma^k \Gamma_k \rho \Gamma_k^\dagger \tag{68} \]

with

\[
H_S(t) = -\mu \vec{S} \cdot \vec{B}(t) \\
\Gamma_+(t) = R(\vec{B}(t)) \sigma_+ R(\vec{B}(t))^\dagger \\
\Gamma_-(t) = R(\vec{B}(t)) \sigma_- R(\vec{B}(t))^\dagger
\]

where \( \vec{S} = \frac{\hbar}{2} \vec{S} \), \( \sigma_+ = \sigma_x - i \sigma_y = \begin{pmatrix} 0 & 0 \\ 2 & 0 \end{pmatrix} \), \( \{\sigma_x, \sigma_y, \sigma_z\} \) are the Pauli matrices, and \( R(\vec{B}) \) is the matrix of the eigenvectors of \( H_S \) expressed in the canonical basis of \( \mathbb{C}^2 \) (the effects of the environment must be described on the dressed basis of the system, see for example ref.\(^{31}\)). This model corresponds to a spin-1/2 interacting with a magnetic field \( \vec{B} \) (\( \mu \) being the coupling constant) with an environment inducing a dephasing modelled by \( \Gamma_+(t) \) and a spontaneous emission from \( |1 \rangle \) to \( |0 \rangle \). \( \gamma^+ \) and \( \gamma^- \) are the square of the probabilities per unit time of these decoherence processes. \( \mathcal{H}_S = \mathbb{C}^2 \) and then \( \mathcal{H}_S \otimes \mathcal{H}_A = \mathbb{C}^4 \). We can rewrite the operators by using spherical coordinates
FIG. 2. Strenght $B$ and colatitude $\theta$ of the magnetic field controlling the spin, with respect to the time $t$ (atomic units). The longitude $\varphi$ is remained to zero.

\[ \vec{B} = B(\sin \theta \cos \varphi \vec{e}_x + \sin \theta \sin \varphi \vec{e}_y + \cos \theta \vec{e}_z) \]  

\[
H_S = -\frac{\mu B}{2} \begin{pmatrix} \cos \theta & e^{-i \varphi} \sin \theta \\ e^{i \varphi} \sin \theta & -\cos \theta \end{pmatrix} 
\]  

\[
R = \begin{pmatrix} \cos \frac{\theta}{2} & -e^{-i \varphi} \sin \frac{\theta}{2} \\ e^{i \varphi} \sin \frac{\theta}{2} & \cos \frac{\theta}{2} \end{pmatrix} 
\]  

\[
\Gamma_+ = \begin{pmatrix} \cos \theta & e^{-i \varphi} \sin \theta \\ e^{i \varphi} \sin \theta & -\cos \theta \end{pmatrix} 
\]  

\[
\Gamma_- = \begin{pmatrix} -e^{-i \varphi} \sin \theta & -2e^{-2i \varphi} \sin^2 \frac{\theta}{2} \\ 2 \cos^2 \frac{\theta}{2} & e^{-i \varphi} \sin \theta \end{pmatrix} 
\]

**b. The dynamics:** We consider the evolution of the magnetic field controlling the spin, which is represented figure 2. We consider the initial condition

\[
\rho(0) = \begin{pmatrix} \epsilon & \epsilon \\ \epsilon & 1 - \epsilon \end{pmatrix} 
\]

with $\epsilon \ll 1$ a very small parameter. We choose this initial condition in order to be close to $\begin{pmatrix} 0 & 0 \\ 0 & 1 \end{pmatrix}$ but without starting from the singular stratum of the pure states $D^0(\mathbb{C}^2)$ (we avoid then the problems induced by the transition from a stratum to another one). The dynamics runs in the regular stratum $D^0(\mathbb{C}^2)$, but the steady state induced by the Lindblad equation is in the singular stratum $D^0(\mathbb{C}^2)$:

\[
\lim_{t \to +\infty} \rho(t) = \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} 
\]

because of the spontaneous emission process. The evolution of $\rho(t)$ solution of the Lindblad equation and the evolution of $\Psi(t)$ solution of the nonlinear Schrödinger equation $i\hbar \dot{\Psi} = ((H_S - \frac{1}{2} \gamma k \Gamma_k \Gamma_k^+ \Gamma_k^\dagger) \otimes 1_{\mathbb{C}^2} + \frac{1}{2} \gamma k \Gamma_k \otimes \Gamma_k^\dagger(\Psi))\Psi$ are represented figure 3. We can note that $\rho(t) = \pi_A(\Psi(t))$ as shown figure 4. The dynamics shown figure 3 can be compared with the other Schrödinger dynamics associated with the system shown figure 5.

**B. Geometric phases of open quantum systems**

**1. The different notions of operator valued phases**

For the open quantum systems, the notion of phase cannot be the same that for the closed systems. In accordance with the $C^*$-module structure of the purification space $\mathcal{H}_S \otimes \mathcal{H}_A$, a phase for an open quantum system is certainly
Right: evolution of the occupation probabilities of the purified state $\Psi(t)$ (solution of the nonlinear Schrödinger equation). $|(ij)\rangle_{i,j=1,2}$ is the canonical basis of $\mathcal{H}_S \otimes \mathcal{H}_A = \mathbb{C}^2 \otimes \mathbb{C}^2$. The parameters are chosen as being (in atomic units) $\mu = 1$, $\gamma^+ = 10^{-3}$, $\gamma^- = 2 \times 10^{-3}$, and $\epsilon = 10^{-5}$.

The Lindblad equation is integrated by using a splitting of the evolution operator $U(t,0) = \mathbb{E}^{e^{-\hbar \mathcal{L}(t')dt'}} = U(t_N, t_{N-1}) \ldots U(t_2, t_1) U(t_1,0)$ (for a partition $0 < t_1 < \ldots < t_N$ of $[0,T]$) with the approximation $U(t_{i+1}, t_i) = \mathbb{E}^{e^{-\hbar f_{i+1}^0\Delta t} \mathcal{L}(t)dt} = e^{-\hbar \mathcal{L}(t_i)\Delta t} + \mathcal{O}(\Delta t^2)$; where $\mathcal{L} = [H_S, \bullet] - \frac{1}{2} \gamma^k \{ \Gamma^*_k \Gamma_k, \bullet \} + \gamma^k \Gamma_k \Gamma^*_k$ is considered as a linear (non-hermitian) operator of the Hilbert-Schmidt space $\mathcal{H}_S \otimes \mathcal{H}_S$ (as a “superoperator” acting on the Liouville representation of $\rho$ : $( \begin{pmatrix} \rho_{11}^0 & \rho_{12}^0 \\ \rho_{21}^0 & \rho_{22}^0 \end{pmatrix} )$).

The nonlinear Schrödinger equation is integrated by using an intermediate representation $\tilde{\Psi}(t) = \Psi^{eff}(t,0)^{-1} \otimes 1_{\mathbb{C}^2} \Psi(t)$ with $\hbar \frac{d}{dt} \Psi^{eff} = (H_S - \frac{1}{2} \gamma^k \Gamma^*_k \Gamma_k)^{\Psi^{eff}}$ integrated by using a splitting on the time partition, and by using a RK4 (Runge-Kutta of order 4) algorithm to integrate the nonlinear part $\frac{\hbar}{2} \frac{d}{dt} \Psi = \frac{\hbar^{-1}}{2} \gamma^k \Psi^{eff} - \Gamma_k \Psi^{eff} \otimes (\Psi^{eff} W_\Psi)^\dagger \Gamma_k^\dagger (\Psi^{eff} W_\Psi)^\dagger \otimes \Psi$, with $W_\Psi = \Psi^{-1}(\Psi)$.

an operator in the $C^*$-algebra $\mathcal{B}(\mathcal{H}_S)$ (we recall that a $C^*$-module mimics the structure of vector space by replacing the ring $\mathbb{C}$ by a $C^*$-algebra).

**Definition 2** We define two different notions of phase in the $C^*$-module for a state $\Psi \in \mathcal{H}_S \otimes \mathcal{H}_A$:

- **We call phase by invariance**, an operator $g \in GL(\mathcal{H}_S)$ leaving invariant the $C^*$-norm:
  \[
  \|g\Psi\|_2^2 = \|\Psi\|_2^2 
  \]

- **We call phase by (unitary) equivariance**, an operator $g \in GL(\mathcal{H}_S)$ leaving equivariant the $C^*$-norm:
  \[
  \|g\Psi\|_2^2 = g\|\Psi\|_2^2 g^{-1} 
  \]
the diagonal density operators with sorted eigenvalues (non-unitary phases. For a stratum $\Sigma^i$ phases by equivariance (or the group of ancilla transformations), and by
\[ U \in \text{GL}(k) \]
left-right action:
\[ \text{GL}(k) \]
Let
\[ S \]
but since we will use only phases by invariance for isospectral transformations (inner to
\[ S \]
and then each (SLOCC or isospectral) transformation of
\[ S \]
For an abelian $C^*$-algebra (as $C$) the two notions are equivalent. We can note that $\forall g \in \text{GL}(H_S), \forall \Psi \in H_S \otimes H_A$ we have
\[ \|g\Psi\|^2 = g\|\Psi\|^2 \]
and then each (SLOCC or isospectral) transformation of $\mathcal{S}$ appears as a phase by non-unitary equivariance (a concept similar with the case of the non-hermitian quantum systems: due to the non-conservation of the norm during the dynamics, we consider “non-unitary phases” $g \in C^*$ correspoding to a change of norm: $\|g\psi\|^2 = |g|^2 \|\psi\|^2$ with $\psi \in H_S$).
Let $\rho \in D(H_S)$. The group of phases by invariance of $\pi_\Lambda^\rho(\sigma)$ is the stabilizer (the isotropy subgroup) of $\rho$ for the left-right action: $GL(H_S)_\rho = \{ g \in GL(H_S), g\rho g^\dagger = \rho \}$. The group of phases by equivariance is $U(H_S) \times GL(H_S)_\rho$.
But since we will use only phases by invariance for isospectral transformations (inner to $\pi_\Lambda^\rho(\sigma)$ with $\sigma = \pi_D(\rho)$), the group is reduced to $U(H_S)$. Because $3g_0 \in GL(H_S)$ such that $\rho = g_0\sigma g_0^\dagger$ (with $\sigma = \pi_D(\rho)$), $g_0 = s u_\rho$ with $u_\rho \in U(H_S)$ an unitary transformation and $s_\rho \in GL(H_S)/U(H_S)$ a SLOCC transformation), we have $GL(H_S)_\rho = GL(H_S)_{g_0\sigma g_0^\dagger} = g_0GL(H_S)_{\sigma}g_0^{-1}$. The isotropy subgroups are then all isomorphic to the same model group for all $\rho$ chosen in a single stratum (but it is different between two strata).
To simplify the notations, we denote by $K = U(H_S) \simeq U(n)$ (or $U(H_A)$ if it acts on the right) the group of the phases by equivariance (or the group of ancilla transformations), and by $G = GL(H_S) \simeq GL(n, C)$ the group of the non-unitary phases. For a stratum $\Sigma^i(H_S)$ we denote by $H^i = GL(H_S)_\sigma \simeq GL(q_i)^{k_i} \times \ldots \times GL(q_i)^{k_i}$ the stabilizer of the diagonal density operators with sorted eigenvalues ($k_i$ is the number of eigenvalues with degeneracy equal to $q_i$).
The group of all phases by invariance of the stratum $\Sigma'(\mathcal{H}_S)$ is the normal closure of $H'$: $\overline{H'} = \bigcup_{g \in G} gH'g^{-1}$ ($\overline{H'}$ is the smallest normal subgroup of $G$ including $H'$).

We can also say that $K$ is the group of the inobservable reconfigurations of the ancilla, $G$ is the group of the unitary and SLOCC transformations of the system performed by the physicist, and $\overline{H'}$ is the subgroup of inefficient transformations of the system (a transformation is inefficient with respect to a particular density operator).

The non-unitary operator valued phases have been defined only with respect to the norm of the $C^*$-module (the projection of purified states onto density operators). But the non-commutativity of the $C^*$-algebra $\mathcal{B}(\mathcal{H}_S)$ and the nonlinearity of the Hamiltonian of the purified dynamics ($H_{\text{purified}} = (H_S - \frac{i}{2} \gamma^k \Gamma^d_k \Gamma_k) \otimes 1_{\mathcal{H}_A} + \frac{i}{2} \gamma^k \Gamma_k \otimes \Gamma^d_k(\bullet)$) induce a difficulty, because the phases do not commute with the generator of the dynamics.

**Definition 3** We call phase with respect to the generator of the dynamics, an operator $g \in G$ such that

$$H_{\text{eff}}(g\Psi)g\Psi = gH_{\text{eff}}(\Psi)\Psi$$

(81)

For closed quantum systems where the Hamiltonian is linear and the phases are scalars, this condition is trivial.

**Proposition 1** The group of the phases with respect to the generator of the dynamics is $G_{\text{eff}} = G_{H_{\text{eff}}} \cap \bigcap_k G_{\Gamma_k}$ ($H_{\text{eff}} = H_S - \frac{i}{2} \gamma^k \Gamma^d_k \Gamma_k$), where the isotropy subgroups are defined for the adjoint action ($G_{H_{\text{eff}}} = \{g \in G; g^{-1} H_{\text{eff}} g = H_{\text{eff}}\}$).

**Proof:** Let $W_\Psi \in \mathcal{B}(\mathcal{H}_S)$ be such that $\Psi(W_\Psi) = \Psi$.

$$H_{\text{eff}}(g\Psi)g\Psi = H_{\text{eff}} \otimes 1_{\mathcal{H}_A}g\Psi \overset{\gamma^k \Gamma_k \otimes \Gamma^d_k(\Psi)g\Psi}{=} H_{\text{eff}}g \otimes 1_{\mathcal{H}_A} \Psi \overset{\gamma^k \Gamma_k g \otimes (gW_\Psi)^* \Gamma_k g W_\Psi}{=} H_{\text{eff}}g \otimes 1_{\mathcal{H}_A} \Psi \overset{\gamma^k \Gamma_k g \otimes (W_\Psi^{-1} g^{-1} \Gamma_k g W_\Psi)^*}{=} H_{\text{eff}}g \otimes 1_{\mathcal{H}_A} \Psi$$

(82)

$$H_{\text{eff}}g = gH_{\text{eff}} \text{ if } g \in G_{H_{\text{eff}}}, \Gamma_k g = g \Gamma_k \text{ if } g \in G_{\Gamma_k} \text{ and } g^{-1} \Gamma_k g = \Gamma_k \text{ if } g \in G_{\Gamma_k}. \quad H_{\text{eff}}(g\Psi)g\Psi = gH_{\text{eff}}(\Psi)\Psi \text{ if } g \in G_{H_{\text{eff}}} \cap \bigcap_k G_{\Gamma_k}.$$

We remark that $\forall k \in K, H_{\text{eff}}(1_{\mathcal{H}_A} \otimes k^T \Psi)1_{\mathcal{H}_A} \otimes k^T \Psi = 1_{\mathcal{H}_A} \otimes k^T H_{\text{eff}}(\Psi) \Psi$ (because $\Gamma^d_k(1_{\mathcal{H}_A} \otimes k^T \Psi) = (k^{-1} W_\Psi \Gamma_k W_\Psi)^* = k^T \Gamma^d_k(\Psi)(k^T)^{-1}$).

We remark moreover that if the system Hamiltonian $H_S$ and/or the jump operators $\Gamma_k$ are time-dependent, $G_{\text{eff}}$ is time-dependent. In that case, a possibility to avoid difficulties is to consider $G_{\text{eff}} = \bigcap_t G_{\text{eff}(t)}$ but this group can be reduced to the unitary center of $\mathcal{B}(\mathcal{H}_S)$ ($U(1)$ in finite dimension) except if $\forall t, H_S(t)$ and $\Gamma_k(t)$ belong to a same (small) subalgebra of $\mathcal{B}(\mathcal{H}_S)$.

2. **Operator valued geometric phases**

For closed quantum systems, the geometric phase concept is related to the cyclicity of the projected dynamics. Let $[0, T] \ni t \mapsto \rho(t) \in \mathcal{D}_0(\mathcal{H}_S)$ be a density operator solution of the Lindblad equation $i\hbar \dot{\rho} = \mathcal{L}(\rho)$. We say that the projected dynamics is cyclic if $\pi_D(\rho(T)) = \pi_D(\rho(0))$ (the spectrum of the statistical probabilities is the same at the start and at the end of the dynamics). We search a density operator $[0, T] \ni t \mapsto \bar{\rho}(t) \in \mathcal{D}(\mathcal{H}_S)$ such that

$$\bar{\rho}(T) = \bar{\rho}(0)$$

(85)

$$\forall t, \exists g(t) \in G, \quad \rho(t) = g(t)\bar{\rho}(t)g(t)^\dagger$$

(86)

$\bar{\rho}$ is the cyclic density operator associated with the density operator of cyclic projection. We note that $g(t) \in G$ and not $K$ because there is no reason for which the transformation of $\rho$ into a cyclic density operator implies no SLOCC operations.

**Theorem 3** A density operator $\rho(t)$ with cyclic projection and its cyclic density operator $\bar{\rho}(t)$ are related by $\rho(t) = g(t)\bar{\rho}(t)g(t)^\dagger$ with the non-unitary operator valued phase $g(t)$ defined by

$$g(t) = \frac{T}{\tau} e^{-i\hbar^{-1} \int_0^T E(g(t'))\bar{\rho}(t')g(t')^\dagger dt'} \frac{T}{\tau} e^{-i\hbar^{-1} \int_0^T (i\hbar\mu(t')^2 + \eta(t')) dt'}$$

(87)
where the dynamical phase generator is defined by

\[ \forall \rho \in \mathcal{D}(\mathcal{H}_S), \quad E(\rho) = H_S - \frac{i}{2} \gamma^k \Gamma_k^\dagger \Gamma_k + \frac{i}{2} \bar{\gamma}^k \Gamma_k^\dagger \rho \ast \in \mathcal{B}(\mathcal{H}_S) \]  

(88)

and the geometric phase generator of the first kind is defined by

\[ \mathfrak{A} = dW W^\ast \in \Omega^1(\mathcal{B}(\mathcal{H}_S), \mathcal{B}(\mathcal{H}_S)) \]  

(89)

\( i_{\hat{W}_\rho} \) is the inner product with \( \hat{W}_\rho \) viewed as a tangent vector, \( W_\rho(t) \) being a standard purification of \( \hat{\rho}(t) \): \( i_{\hat{W}_\rho} \mathfrak{A} = W_\rho(t) W_\rho(t)^\ast \). The geometric phase generator of the second kind is defined as

\[ \eta(t) = W_\rho(t) \dot{k}(t) k(t)^{-1} W_\rho(t)^\ast + h(t) \in \mathcal{B} \]  

(90)

with \( k(t) \in K \) and \( h(t) \in \mathcal{B}(\ker \hat{\rho}(t)) \) (\( \mathcal{B} \) is the Lie algebra of \( \mathcal{H} \) with \( i \) the index of the stratum of \( \hat{\rho} \)).

We can note that

\[ \mathfrak{A} \| \Psi(W) \|^2 = \langle \Psi(W) | d\Psi(W) \rangle \ast = \text{tr}_{\mathcal{H}_A} |d\Psi(W)\rangle \langle \Psi(W)| \]  

(91)

This definition is similar to the definition of the non-unitary geometric phase generator of non-hermitian closed quantum systems (with the \( C^* \)-module in place of the Hilbert space of the system). It is moreover the non-adiabatic generalisation of the \( C^* \)-geometric phase introduced in ref.\textsuperscript{19,20,22,31}. We can also show that

\[ d\rho = \mathfrak{A} \rho + \rho \mathfrak{A}^\dagger \]  

(92)

The definition of the dynamical phase \( T e^{-i \int_0^t E(g_\rho g^\dagger) dt} \) induces that the definition of total phase \( g(t) \) is implicit (the expression of \( g \) depends on itself). This is a consequence of the nonlinearity of the Schrödinger equation of the purified dynamics (we can say that the dynamical phase is a “nonlinear dynamical phase”).

We can remark that \( h(t) = 0 \) if the cyclic dynamics (\( t \mapsto \hat{\rho}(t) \)) takes place in regular strata.

**Proof:** Since \( \rho = g_\rho g^\dagger \), \( \exists k \in K \) such that \( W_\rho = g_\rho W_k \). The nonlinear Schrödinger equation (for a standard purification state) is

\[ i\hbar \dot{W}_\rho = H^{eff} W_\rho + \frac{i}{2} \gamma^k \Gamma_k W_\rho^\dagger \Gamma_k^\dagger \Psi(W_\rho)^\dagger \]  

(93)

\[ = H^{eff} W_\rho + \frac{i}{2} \gamma^k \Gamma_k W_\rho^\dagger \Gamma_k^\dagger W_\rho^\dagger \]  

(94)

\[ = H^{eff} W_\rho + \frac{i}{2} \gamma^k \Gamma_k W_\rho^\dagger \Gamma_k^\dagger W_\rho^\dagger \]  

(95)

with \( H^{eff} = H_S - \frac{i}{2} \gamma^k \Gamma_k^\dagger \Gamma_k \). It follows that

\[ \dot{g} W_\rho k + g \dot{W}_\rho k + g W_\rho \dot{k} = -i \hbar^{-1} \left( H^{eff} g W_\rho k + \frac{i}{2} g^{-1} \Gamma_l g W_\rho W_\rho^\dagger \Gamma_l^\dagger (g^\dagger)^{-1} (W_\rho^\dagger)^k \right) \]  

(96)

and then

\[ g^{-1} \dot{g} W_\rho + W_\rho \dot{k} k^{-1} = -\dot{W}_\rho - i \hbar^{-1} \left( g^{-1} H^{eff} g W_\rho + \frac{i}{2} g^{-1} \Gamma_l g W_\rho W_\rho^\dagger \Gamma_l^\dagger (g^\dagger)^{-1} (W_\rho^\dagger)^k \right) \]  

(97)

By multiplying on the right this expression by \( W_\rho^\dagger \) we find

\[ g^{-1} \dot{g} + W_\rho k k^{-1} W_\rho^\dagger = -\dot{W}_\rho W_\rho^\dagger - i \hbar^{-1} g^{-1} E(g_\rho g^\dagger) g - h \]  

(98)

with \( h \in \mathcal{B}(\ker \hat{\rho}) \). We set \( \eta = W_\rho k k^{-1} W_\rho^\dagger + h \). Let \( g_\lambda \) be such that \( g = T e^{-i \int_0^t E(g_\rho g^\dagger) dt} g_\lambda \).

\[ \dot{g} = -i \hbar^{-1} E(g_\rho g^\dagger) g + T e^{-i \int_0^t E(g_\rho g^\dagger) dt} \]  

(99)

\[ g^{-1} \dot{g} = -i \hbar^{-1} g^{-1} E(g_\rho g^\dagger) g + g_\lambda^{-1} \dot{g} \]  

(100)

It follows that

\[ g_\lambda^{-1} \dot{g} \lambda = -\dot{W}_\rho W_\rho - \eta \Rightarrow g_\lambda = T e^{-i \int_0^t (W_\rho W_\rho^\dagger + \eta) dt} \]  

(101)
One needs now only to show that \( \eta \in \mathfrak{h}^\dagger \):

\[
\eta \dot{\rho} + \dot{\eta} \rho^\dagger = W_\rho \dot{k} k^{-1} W_\rho^\dagger + W_\rho \frac{dk^{-1}}{dt} W_\rho^\dagger = W_\rho \dot{k} k^{-1} W_\rho^\dagger - W_\rho \dot{k} k^{-1} W_\rho^\dagger = 0
\]

since \( \dot{\rho} = W_\rho W_\rho^\dagger, \frac{dk^{-1}}{dt} = -k^{-1} \dot{k} k^{-1} \) and \( h\dot{\rho} = 0 \). Because of \( g_\rho^{-1} H g_\rho = GL(H_\rho) \rho = \{ g \in GL(H_\rho), g\dot{\rho} g^\dagger \dot{\rho} \} \) \( \dot{\rho} = g_\rho \pi_D(\dot{\rho}) g_\rho^\dagger \), the Lie algebra of \( GL(H_\rho) \) is \( \mathfrak{gl}(H_\rho) = \{ X \in \mathfrak{B}(H_\rho), X\rho + \rho X^\dagger = 0 \} \). We have then \( \eta \in \mathfrak{gl}(H_\rho) \rho \subset \mathfrak{h}^\dagger \).

From the point of view of the purified dynamics, we have

\[
\Psi_\rho(t) = \mathcal{T}_e^{-th^{-1}} \int_0^t E(g_\rho g^\dagger) dt E^{−h}(\dot{W}_\rho \mathfrak{A} + \eta) dt \odot k(t) \Psi_\rho(t)
\]

with \( \Psi_\rho = \Psi(W_\rho) \), and \( i_{\dot{W}_\rho} \mathfrak{A} \parallel \Psi_\rho \parallel^2 = (\Psi_\rho | \dot{\Psi}_\rho)_* \).

The right geometric phase \( k(t) \in K \) is arbitrary in the sense that \( \pi_{HS}(g_W k) = g_\rho g^\dagger = \pi_{HS}(g_W) \), but it induces the geometric phase generator of the second kind \( \eta_k = W_\rho \dot{k} k^{-1} W_\rho^\dagger \) in the left geometric phase. Let \( A^R \in \Omega^1(\mathfrak{B}(H_S), \mathfrak{B}(H_S)) \) be the generator of the right geometric phase:

\[
k(t) = \mathcal{T}_e^{-h (i_{W_\rho} W_\rho^\dagger) A_R} dt
\]

A possible choice consists to use the definition of the Uhlmann geometric phase \( Uhl \mathfrak{A} \):

\[
dW = Uhl \mathfrak{A} W + W A^R
\]

where \( Uhl \mathfrak{A} \) is solution of the following equation:

\[
d\rho = Uhl \mathfrak{A} \rho + \rho Uhl \mathfrak{A} \quad Uhl \mathfrak{A}^\dagger = Uhl \mathfrak{A}
\]

This choice is set in order to \( W_\parallel = W_\rho \dot{k} \) satisfies \( W_\parallel W_\parallel^\dagger = \dot{W}_\parallel W_\parallel^\dagger \Leftrightarrow \dot{W}_\parallel W_\parallel^* = W_\parallel^* W_\parallel^\dagger \), which is the Uhlmann’s definition of the parallel transport for the density matrices. With this choice of right geometric phase, we have:

\[
i_{W_\rho} \mathfrak{A} + W_\rho \dot{k} k^{-1} W_\rho^* = i\dot{W}_\rho \left( \mathfrak{A} + W A^R W^* \right) = i\dot{W}_\rho \left( dW W^* + W A^R W^* \right) = i\dot{W}_\rho \left( Uhl \mathfrak{A} \right)
\]

The left generator appearing in the definition of the Uhlmann (right) geometric phase, generates then the total left geometric phase:

\[
\mathcal{T}_e^{-\int_0^T (i_{W_\rho} \mathfrak{A} + \eta_k(t)) dt} \mathcal{T}_e^{-\int_0^T i_{W_\rho} \mathfrak{A} Uhl \mathfrak{A} dt} = \mathcal{T}_e^{-\int_0^T i_{W_\rho} \mathfrak{A} Uhl \mathfrak{A} dt} = \mathcal{P}_e^{-\int_\mathcal{C} Uhl \mathfrak{A}}
\]

where \( \mathcal{C} \) is the closed curve parametrized by \( [0, T] \ni t \mapsto W_\rho(t) \in \mathfrak{B}(H_S) \sim \mathfrak{M}_{n \times n}(\mathbb{C}) \) viewed as a manifold (\( \mathcal{P}_e \) denoting the path-anti-ordered exponential).

Since the total left geometric phase is automatically adapted to the choice of the right geometric phase (by the presence of the left geometric phase generator of the second kind \( \eta_k = W_\rho \dot{k} k^{-1} W_\rho^* \)), no natural choice of right geometric phase is imposed by the nonlinear Schrödinger equation and its associated Lindblad equation. Other definitions of the right geometric phase corresponding to other Uhlmann like connections can be choiced. This is the reason for which Dittman, Uhlmann and Rudolph have find large classes of connections defining right geometric phases and compatible with the density matrix theory.
3. Special cases of left geometric phases

a. Geometric phase with respect to the generator of the dynamics: We suppose that the dynamics takes place in regular strata. Let \( g_\mathcal{L} \) be the Lie algebra of \( G_\mathcal{L} \) and let \( \forall \Psi \in \mathcal{H}_S \otimes \mathcal{H}_A, S_\mathcal{L}(\Psi) = g_\mathcal{L} \Psi \) be the Hilbert subspace which is the orbit of \( \Psi \) by \( g_\mathcal{L} \). Let \( \{X_i\}_i \) be a set of generators of the Lie algebra \( g_\mathcal{L} \) such that \( \text{tr}(X_i^i X_j) = \delta_j^i \). By construction \( \{\Psi(X_i W)\}_i \) constitutes a basis of \( S_\mathcal{L}(\Psi(W)) \) (with \( W \in \mathcal{B}(\mathcal{H}_S) \)). In spite of the orthonormalisation of the generators of \( g_\mathcal{L} \), the basis \( \{\Psi(X_i W)\}_i \) is not orthonormal. Let \( \{\Psi(X_i(W)^{-1})\}_i \) be the associated biorthonormal basis:

\[
\langle \Psi(X_i(W)^{-1})|\Psi(X_j W) \rangle = \langle X_i(W)^{-1}|X_j W \rangle_{HS} = \text{tr}(W^{-1}X_i^i X_j W) = \text{tr}(WW^{-1}X_i^i X_j) = \text{tr}(X_i^i X_j) = \delta_j^i
\]

(where we have used the cyclicity of the trace). Let \( \Psi(P_\mathcal{L}(W)) \) be the (non-orthogonal) projection onto \( S_\mathcal{L}(\Psi(W)) \) in \( \mathcal{HS} \otimes \mathcal{HA} \) defined by

\[ P_\mathcal{L}(W) = |X_i W\rangle_{HS} \langle X_i(W)^{-1}| = X_i W \text{tr}(W^{-1}X_i^i \bullet) \]  

Let \( A^L \in \Omega^1(\mathcal{B}(\mathcal{H}_S), g_\mathcal{L}) \) be defined as

\[
A^L = \frac{1}{2} \{\Psi(W)\}^2 = \langle \Psi(W)|\Psi(P_\mathcal{L}(W))[d\Psi(W)]\rangle
\]

\[
\begin{align*}
A^L W W^\dagger &= P_\mathcal{L}(W)[dW] W^\dagger \quad (120) \\
A^L W W^\dagger &= \text{tr}(W^{-1}X_i^i dW) X_i W W^\dagger \quad (121) \\
A^L &= \text{tr}(X_i^i dWW^\dagger) X_i \quad (122) \\
A^L &= \text{tr}(X_i^i \mathcal{A}) X_i \quad (124)
\end{align*}
\]

\( A^L \) is the part of \( \mathcal{A} \) which induces a phase with respect to the generator of the dynamics.

Proposition 2 \( i_{W_\rho} \mathcal{A} = i_{W_\rho} A^L \) (the geometric phase is a phase with respect to the generator of the dynamics) if and only if \( E(\rho) \in g_\mathcal{L} \):

\[
\begin{align*}
[E(\rho), H^{eff}] &= 0 \quad (125) \\
E(\rho), I_k^1 &= 0 \quad (126) \\
E(\rho), \Gamma_k^1 &= 0 \quad (127)
\end{align*}
\]

Proof: \( i_{W_\rho} \mathcal{A} = \hat{W}_\rho W_\rho \) and \( W_\rho = -g^{-1}gW_\rho + g^{-1}W_\rho k^{-1} - W_\rho \hat{k}k^{-1} \). We have then \( i_{W_\rho} \mathcal{A} = -g^{-1}g - i\hbar g^{-1}E(\rho)g - \eta_k \).

\( i_{W_\rho} \mathcal{A} \in g_\mathcal{L} \) if \( g \in G_\mathcal{L} \) and \( E(\rho) \in g_\mathcal{L} \). \( i_{W_\rho} \mathcal{A} \in g_\mathcal{L} \).

Note that \( g \in G_\mathcal{L} \Rightarrow E(g\rho g^\dagger) = gE(\rho)g^{-1} \). It follows that

\[
g(t) = \int e^{-iH^{eff}_t} g(t) E(\rho(t)) g(t)^{-1} dt \int e^{-iW_\rho(t)} A^L + \eta_k dt\]

\[
= \int e^{-iH^{eff}_t} g(t) E(\rho(t)) dt - \int e^{-iW_\rho(t)} (A^L + \eta_k) dt\]

In that case, the nonlinearity of the dynamical phase does not then occur but the dynamical and the geometric phases are not separated.

b. Geometric phase by invariance: We suppose that the dynamics is inner to a regular stratum \( \Sigma'(\mathcal{H}_S) \). Let \( H' \simeq GL(q_1) \times ... \times GL(q_k) \) be the stabilizer of the stratum \( \Sigma'(\mathcal{H}_S) \) (we do not consider necessary that \( q_j \neq q_k \) for \( j \neq k \)). Let \( \mathfrak{h}' \simeq u(q_1) \oplus ... \oplus u(q_k) \) be its Lie algebra. \( \forall \sigma \in \Sigma'(\mathcal{H}_S) \), let \( \mathcal{P}^\sigma: \mathcal{B}(\mathcal{H}_S) \rightarrow \mathfrak{h}' \) be defined by

\[
\mathcal{P}^\sigma(X) = P_j^\sigma X P_j^\sigma
\]

where \( P_j^\sigma \) is the orthogonal projection onto the \( q_j \)-dimensional eigenspace of \( \sigma \) associated with the eigenvalue \( p_j \) (which has a degeneracy equal to \( q_j \)). Let \( \rho \in \mathcal{D}(\mathcal{H}_S) \) be such that \( \pi_D(\rho) = \sigma \). We know that \( \exists g_\rho \in G \) such that \( \rho = g_\rho \sigma g_\rho^\dagger \)
and $GL(H_S)_\rho = g_\rho H^1 g_\rho^{-1}$. Let $\mathcal{P}^\rho : \mathcal{B}(H_S) \to \mathfrak{g}l(H_S)_\rho$ be defined by $\mathcal{P}^\rho(X) = P^{ij} X P^\rho_j$ with $P^\rho_j = g_\rho P^\sigma_j g_\rho^{-1}$.

Let $A^{BL} \in \Omega^1(\mathcal{B}(H_S), \mathfrak{h})$ be defined as

$$A^{BL} = \mathcal{P}^{WW^\dagger}(\mathfrak{A}) = P^{WW^\dagger} dW W^{-1} P^{WW^\dagger}_{\rho}$$

(131)

$A^{BL}$ is the part of $\mathfrak{A}$ which induces a phase by invariance.

**Proposition 3** $i_{W^\rho} \mathfrak{A} = i_{W^\rho} A^{BL}$ (the geometric phase is a phase by invariance) if and only if $E_{\rho}(\sigma) \in \mathfrak{h}^i$ with $E_{\rho}(\sigma) = g_\rho^{-1} E(g_\rho \sigma g_\rho^{-1}) g_\rho$ ($g_\rho \in U(H_S)$, $\rho(t) = g_\rho(t) \sigma g_\rho(t)^{-1} \in T_0(H_S)$).

**Proof:** $i_{W^\rho} \mathfrak{A} = -g_\rho^{-1} g - i h g^{-1} E(\rho) g - \eta_k$ and then $i_{W^\rho} \mathfrak{A} \in \mathfrak{g}l(H_S)_\rho$ if $g \in GL(H_S)_\rho$ and $E(\rho) \in \mathfrak{g}l(H_S)_\rho \iff g_\rho^{-1} E(\rho) g_\rho \in \mathfrak{h}^i$.

The geometric phase (and the dynamical phase) are phase by invariance, i.e. $\rho(T) = \rho(0)$ (the density operator is cyclic), if

$$g_\rho^{-1} H \sigma g_\rho \in \mathfrak{h}^i$$

(132)

The elements of $\mathfrak{g}l(H_S)_\rho$ acting on the left can be converted as elements acting on the right:

$$X \in \mathfrak{g}l(H_S)_\rho \Rightarrow X \rho + \rho X^\dagger = 0$$

(133)

$$\Rightarrow X W W^\dagger + W W^\dagger X^\dagger = 0$$

(134)

$$\Rightarrow X + W W^\dagger X(W^{-1})^\dagger = 0$$

(135)

$$\Rightarrow X W = -W(W^{-1} X W)^\dagger$$

(136)

The left action of $X \in \mathfrak{g}l(H_S)_\rho$ is then equivalent to the right action of $-(W^{-1} X W)^\dagger$. We have then

$$\mathfrak{A} W = (\mathfrak{A} - A^{BL}) W + W A^{BR}$$

(137)

with

$$A^{BR} = -P_{\sigma}^\rho dW^\dagger (W^{-1})^\dagger P_{\sigma}^\rho$$

(138)

Let $W \in S_{HSB}(H_S)$. $dW^\dagger (W^{-1}) = d\sqrt{\sigma} d\sqrt{\sigma}_W g_{WW^\dagger} g_{WW^\dagger} \sqrt{\sigma}_W$. Since $d\sigma = d\sqrt{\sigma} d\sqrt{\sigma} \Rightarrow d\sqrt{\sigma}_W g_{WW^\dagger} g_{WW^\dagger} \sqrt{\sigma}_W$ we have

$$dW^\dagger (W^{-1}) = d\sigma^{-1} - \sqrt{\sigma}_W d\sqrt{\sigma}_W \sqrt{\sigma}_W$$

(141)

But $W^\dagger dW^{-1} = \sqrt{\sigma}_W g_{WW^\dagger} g_{WW^\dagger} \sqrt{\sigma}_W$, and then

$$dW^\dagger (W^{-1}) = d\sigma^{-1} - W^\dagger dW^{-1} \sigma^{-1}$$

(142)

Finally, the restriction of $A^{BR}$ onto $S_{HSB}(H_S)$ is

$$A^{BR}_{\mid S_{HSB}(H_S)} = P_{\sigma}^\rho dW^\dagger P_{\sigma}^\rho \sigma^{-1} - P_{\sigma}^\rho d\sigma^{-1} P_{\sigma}^\rho$$

(143)

This is the expression of the generator of the Sjöqvist-Andersson geometric phase (16-18) (note that in the works of Sjöqvist and Andersson, $\sigma^{-1} = 0$ since they consider only isospectral dynamics). $A^{BR} = -P_{\sigma}^\rho dW^\dagger (W^{-1})^\dagger P_{\sigma}^\rho$ is then the non-unitary generalization of the generator of the Sjöqvist-Andersson geometric phase. We can note that equation (137) can rewritten as

$$dW = (\mathfrak{A} - A^{BL}) W + W A^{BR}$$

(144)
which is an equation defining an Uhlmann like connection. In other words, we can choose the right geometric phase as being the Sjöqvist geometric phase in place of the Uhlmann geometric phase \((k k^\dagger = -A^{BL})\). In that case, the total left geometric phase is such that

\[
\mathcal{T}_L - \int_0^T (\Psi \dot{\gamma})(k \cdot \alpha + \eta(k))dt \in G/G_{\rho}
\]  

We will say that this Sjöqvist geometric phase is two-sided in the sense that it can be considered on the left \((A^{BL})\) as a inefficient transformation of the system, or it can be considered on the right \((A^{BR})\) as a reconfiguration of the ancilla. Its invariance nature implies that it can be revealed only by interferometry in accordance with its discovery by Sjöqvist et al.\[16,17\].

c. Adiabatic geometric phase: Suppose that \(t \mapsto H_S(t)\) and \(t \mapsto \Gamma_k(t)\) are continuous and cyclic operators with respect to the time: \(H_S(T) = H_S(0)\) and \(\Gamma_k(T) = \Gamma_k(0)\). Moreover suppose that \(|\gamma| = \max_k |\gamma_k| \ll 1\). The nonlinear Schrödinger equation for the purified dynamics can be written as

\[
\hbar \ddot{\Psi} = H^\text{eff} \otimes 1_{H_A} \Psi + \frac{i}{2} \gamma^k \Gamma_k \otimes (W^{(0)}|\Gamma_k|^\dagger W^{(0)*}) \dot{\Psi} + O(|\gamma|^2)
\]

with \(\Psi^{(0)} = \Psi(W^{(0)})\) be such that:

\[
\hbar \ddot{\Psi}^{(0)} = H_S \otimes 1_{H_A} \Psi^{(0)}
\]

At the first order of perturbation, the nonlinearity is replaced by the pre-integration of the zero-order solution. Suppose that \(\Psi^{(0)}(t = 0) = \psi(t = 0) \otimes \xi_\alpha\), then \(\Psi^{(0)}(t) = \psi(t)(t) \otimes \xi_\alpha\) with \(\hbar \ddot{\Psi}^{(0)} = H_S \psi^{(0)}\) and

\[
W^{(0)} = |\psi^{(0)}\rangle \langle \xi_\alpha| \quad \text{and} \quad W^{(0)*} = |\xi_\alpha\rangle \langle \psi^{(0)}|
\]

\[
W^{(0)*} \Gamma_k W^{(0)} = \langle \psi^{(0)}| \Gamma_k |\psi^{(0)}\rangle |\xi_\alpha\rangle \langle \psi^{(0)}|
\]

Let \(\lambda^{(0)}(t)\) be the instantaneous eigenvalues of \(H_S(t)\) (supposed non-degenerate) and \(\zeta^{(0)}(t)\) be the associated normalized eigenvectors:

\[
H_S \zeta^{(0)} = \lambda^{(0)} \zeta^{(0)}
\]

At the first order of the perturbation, the eigenvalues and the eigenvectors of \(H^\text{eff}(t)\) are

\[
\mu_b = \mu_b^{(0)} - \frac{i}{2} \gamma^k (\zeta_b | \Gamma_k | \zeta^{(0)} + O(|\gamma|^2)
\]

\[
\zeta_b = \zeta_b^{(0)} - \frac{i}{2} \sum_{b \neq b} \gamma^k (\zeta_b | \Gamma_b | \zeta_b^{(0)}) - \frac{i}{2} \gamma^k (\zeta_b^{(0)}| \Gamma_b | \zeta_b^{(0)}) - O(|\gamma|^2)
\]

The eigenvalues and the eigenvectors of \(H_{\mathcal{U}}\) are then

\[
\lambda_{\alpha \beta} = \mu_b + \frac{i}{2} \delta_{\alpha \beta} \gamma^k (\zeta_b | \Gamma_b | \zeta_b^{(0)}) + O(|\gamma|^2)
\]

\[
\Phi_{\alpha \beta} = \zeta_b \otimes \xi_\beta + \frac{i}{2} \delta_{\alpha \beta} \sum_{d \neq b} \gamma^k (\zeta_b | \Gamma_b | \zeta_d^{(0)}) (\psi^{(0)}| \Gamma_d | \psi^{(0)}) (\zeta_b^{(0)}| \Gamma_d | \zeta_d^{(0)}) (\psi^{(0)}| \Gamma_d | \psi^{(0)}) + O(|\gamma|^2)
\]

where \((\xi_\beta\rangle\) is an arbitrary (time independent) basis of \(H_A\). The eigenvectors of \(H_{\mathcal{U}}\) are

\[
\Phi^{*}_{\alpha \beta} = \zeta_b^{*} \otimes \xi_\beta - \frac{i}{2} \delta_{\alpha \beta} \sum_{d \neq b} \gamma^k (\zeta_d^{(0)}| \Gamma_d | \zeta_b^{(0)}) (\psi^{(0)}| \Gamma_d | \psi^{(0)}) (\zeta_d^{(0)}| \Gamma_d | \zeta_d^{(0)}) (\psi^{(0)}| \Gamma_d | \psi^{(0)}) \zeta_d^{(0)} \otimes \xi_\alpha + O(|\gamma|^2)
\]

with \(\zeta^{(0)}\) the eigenvectors of \(H^\text{eff} + \mu\) which are biorthonormal to the eigenvectors of \(H^\text{eff}\) \((\langle \zeta^{(0)}| \zeta^{(0)}\rangle = \delta_{\alpha \beta}\).

We suppose that \(\Psi(t = 0) = \Phi_{\alpha \alpha}(t = 0)\), \(\lambda_{\alpha \alpha}\) being non-degenerate. If the evolution is slow and under some technical assumptions, we can prove the following adiabatic transport formula (see ref.\[16\]):

\[
\rho(t) = g(t) \rho_{\alpha \alpha}(t) g(t)^\dagger + O \left( \max \left( \frac{1}{T}, |\gamma|^2 \right) \right)
\]
\[ g(t) = \mathcal{T} e^{-i \hbar^{-1} \int_0^T H_0^T(t) dt \mathcal{T}} e^{-i \hbar^{-1} \int_0^T A_0^T(t) dt} \]  
\[ \rho_{\alpha \alpha} = \text{tr}_{\mathcal{H}_A} | \Phi_{\alpha} \rangle \langle \Phi_{\alpha} | = | \xi_{\alpha} \rangle \langle \xi_{\alpha} | + \mathcal{O}(|\gamma|^2) \]  
\[ E_{\alpha}^{(1)} = \sum_b \lambda_{\beta \alpha} | \xi_{\alpha} \rangle \langle \xi_{\alpha} | \]  
\[ A_{\alpha}^{(1)} = \sum_{b \neq \alpha} \langle \xi_{\alpha} | \langle \xi_{\alpha} | \langle \xi_{\alpha} | \]  
\[ \zeta_{\alpha}^{(1)} = \zeta_{\alpha} + \frac{i}{2} \sum_{\alpha \neq \beta} \gamma_{\alpha \beta} \mu_{\alpha} - \mu_{\beta} + \frac{i}{2} \gamma_{\alpha \beta} \left( | \xi_{\alpha} \rangle \langle \xi_{\alpha} | \langle \xi_{\alpha} | \right) \]  
\[ \zeta_{\alpha}^{(1)*} = \zeta_{\alpha} - \frac{i}{2} \sum_{\alpha \neq \beta} \gamma_{\alpha \beta} \mu_{\alpha} - \mu_{\beta} + \frac{i}{2} \gamma_{\alpha \beta} \left( | \xi_{\alpha} \rangle \langle \xi_{\alpha} | \langle \xi_{\alpha} | \right) \]  

The adiabatic geometric phase issued from the adiabatic theorem \[ 33 \] \[ \mathcal{T} e^{-i \hbar^{-1} \int_0^T A_0^T(t) dt} \] is related to the non-adiabatic geometric phase as follows. The role of \( \bar{\rho}(t) \) in theorem \[ 3 \] is played by \( \rho_{\alpha \alpha}(t) \). We have \( W_{\rho_{\alpha \alpha}} = | \xi_{\alpha} \rangle \langle \xi_{\alpha} | \) and \( W_{\rho_{\alpha \alpha}}^{*} = | \xi_{\alpha} \rangle \langle \xi_{\alpha} | \). It follows that

\[ i W_{\rho_{\alpha \alpha}} \mathcal{A} = \dot{W}_{\rho_{\alpha \alpha}} W_{\rho_{\alpha \alpha}}^{*} = \frac{d}{dt} \zeta_{\alpha}^{(1)*} \]  

and

\[ A_{\alpha}^{(1)} = i W_{\rho_{\alpha \alpha}} \mathcal{A} + \sum_{c \neq \alpha} \frac{d}{dt} \zeta_{\alpha}^{(1)*} + \mathcal{O}(|\gamma|^2) \]  

where we have use the fact that \( \left( \zeta_{\alpha}^{(1)} ; \zeta_{\alpha}^{(1)*} \right) \) constitutes (at the order \(|\gamma|^2|\) a biorthonormalized basis of \( \mathcal{H}_S \) \( \sum_{\alpha} \zeta_{\alpha}^{(1)} \zeta_{\alpha}^{(1)*} = 1 \)). Moreover

\[ \sum_{c \neq \alpha} \frac{d}{dt} \zeta_{\alpha}^{(1)*} + \mathcal{O}(|\gamma|^2) \]  

It follows that \( \eta = \sum_{c \neq \alpha} \frac{d}{dt} \zeta_{\alpha}^{(1)*} \) \( \in \mathfrak{gl}(\mathcal{H}_S)_{\rho_{\alpha \alpha}} \) and then

\[ A_{\alpha}^{(1)} = i W_{\rho_{\alpha \alpha}} \mathcal{A} + \eta \]  

The adiabatic geometric phase generator \( A_{\alpha}^{(1)} \) found in ref. \[ 33 \] is the sum of the two geometric phase generators found theorem \[ 3 \] with the “density eigenmatrix” \( \rho_{\alpha \alpha} \) playing the role of \( \bar{\rho}(t) \).

Let \( P_{\alpha} = \sum_{b} | \Phi_{\alpha \alpha} \rangle \langle \Phi_{\alpha \alpha} | \) be the eigenprojection in \( \mathcal{H}_S \otimes \mathcal{H}_A \) associated with the eigenvectors of \( H_d \) related to \( \xi_{\alpha} \) by perturbation. We consider the following reduced generator of geometric phases:

\[ \text{tr}_{\mathcal{H}_A} \left( | P_{\alpha} \frac{d}{dt} \Phi_{\alpha \alpha} \rangle \langle \Phi_{\alpha \alpha} | \right) \rho_{\alpha \alpha}^{*} = \sum_{b} \zeta_{\alpha}^{(1)*} | \xi_{\alpha} \rangle \langle \xi_{\alpha} | \zeta_{\alpha}^{(1)*} + \mathcal{O}(|\gamma|^2) \]  
\[ = \frac{d}{dt} \zeta_{\alpha}^{(1)*} + \mathcal{O}(|\gamma|^2) \]
TABLE III. The different geometric phases of the open quantum systems.

| geometric phase                          | generator | values | side  | type               | interpretation                        |
|----------------------------------------|-----------|--------|-------|--------------------|---------------------------------------|
| C*-geometric phase                     | $\mathcal{A}$ | $G$    | left  | by equivariance    | transformations to cyclic density operators |
| Uhlmann geometric phase                | $A^L$     | $K$    | right | by invariance      | transition probability parallelism     |
| Sjöqvist geometric phase               | $A^{BL}/A^{BR}$ | $\mathcal{H}$ | two-sided | by invariance | interferometric phase                 |
| reduced C*-geometric phase             | $A^L$     | $G_L$  | left  | w.r.t. the dynamics | closest to the adiabatic phase         |

$$
\Psi^{-1}(P_{\alpha}) [\hat{W}_{\rho_{\alpha}}] W^*_{\rho_{\alpha}} = A^{(1)}_{\alpha} + \mathcal{O}(|\gamma|^2)
$$

Moreover

$$
E^{(1)}_{\alpha} \otimes |\xi_{\alpha}| \langle \xi_{\alpha} | = P_{\alpha} H_{td}(\Phi_{\alpha}) P_{\alpha}
$$

The geometric and dynamical phase generators appearing in the adiabatic theorem ref.33 are clearly the adiabatic limit of the generators introduced in theorem 38.

Let $G(\Phi_{\alpha})_{ad}(t) \subset U(\mathcal{H}_S)$ be the group of operators of $\mathcal{H}_S$ acting on the eigenvectors of $H_{td}$ as phase changes. By definition we have

$$
\forall g \in G(\Phi_{\alpha})_{ad} : H_{td}(g\Phi_{\alpha}) g\Phi_{\alpha} = \lambda_{\alpha} g\Phi_{\alpha} + \mathcal{O}(|\gamma|^2)
$$

Clearly $E(g_{\rho_{\alpha}} g^{-1}) = E(\rho_{\alpha})$ and $G(\Phi_{\alpha})_{ad} \subset G_L$. The adiabatic geometric phase is a phase with respect to the generator of the dynamics and $A^{(1)}_{\alpha} = i\hat{W}_{\rho_{\alpha}} A^L$. Finally the adiabatic assumption can be rewritten as $i\hat{W}_{\rho_{\alpha}} A \simeq i\hat{W}_{\rho_{\alpha}} A^L$ in accordance with the discussion found in ref.19. The geometric structure involved by the adiabatic geometric phases has been extensively studied in ref.19 and the interpretation of the adiabatic operator valued geometric phase has been studied in ref.33.

This approach for the adiabatic geometric phases, which is useful for bipartite quantum systems, is strongly limited for the open quantum systems described by a Lindblad equation. Indeed both the perturbative assumption and the adiabatic assumption are too drastic because they involve that the dynamics remains in the neighbourhood of the singular stratum of the pure states ($\rho_{\alpha}$ is a pure state at the first order of perturbation). This excludes the more interesting cases where the relaxation rates are sufficiently large to deviate the dynamics or where the interaction duration is sufficiently large to the dynamics goes to the steady state (with the open quantum systems there is a competition between the adiabatic and the relaxation processes). In second order of perturbation the adiabatic approximation deals with mixed state ref.33 but the nonlinearity could induce strong difficulties to applied this approach. A more general approach of the adiabatic geometric phases could consists to use the notion of noncommutative eigenvalues as introduced in ref.19 for bipartite quantum systems, but the nonlinearity could also induce strong difficulties.

Table III summarizes the different geometric phases of the open quantum systems.

4. Example: control of a two-level system with dephasing and spontaneous emission

We return to the illustrative example introduced in the previous section. Let $t \mapsto \rho(t)$ be the evolution described by the left part of figure 3. By construction $\lim_{t \to 0} \pi_D(\rho(0)) = \lim_{t \to +\infty} \pi_D(\rho(t)) = \Sigma^0(\mathcal{H}_S)$ (the vertex associated with the pure states). The projected dynamics is then cyclic. The definition of the geometric phase depends on the choice of the local section $t \mapsto \hat{W}(t) \in \mathcal{B}(\mathcal{H}_S)$ such that $\exists g(t) \in G, \rho(t) = g(t)\hat{W}(t)\hat{W}(t)^\dagger g(t)^\dagger$ and $\lim_{t \to +\infty} \hat{W}(t) = \lim_{t \to 0} \hat{W}(0)$. We consider three interesting cases:

- the section $\sqrt{\sigma} \in \Gamma(\Sigma(\mathcal{H}_S), \mathcal{B}(\mathcal{H}_S))$ associated with the global section of the composite bundle: $\sqrt{\sigma(t)} = \left(\begin{array}{ccc} \sqrt{p(t)} & 0 \\ 0 & \sqrt{1-p(t)} \end{array}\right)$ where $t \mapsto p(t) = \min \text{Sp}(\rho(t)) \in \Sigma(2) = [0, \frac{1}{2}]$ ($\sigma \in \Gamma(\Sigma(\mathcal{H}_S), \mathcal{D}(\mathcal{H}_S))$ being the global section of diagonal density matrices);
FIG. 6. Evolution of the populations and of the coherences of $\sigma(t)$ (left), $\rho^{str-ad}(t)$ (middle), and $\rho^{wk-ad}(t)$ (right).

FIG. 7. Left: Representation of the dynamics $t \mapsto \rho(t)$, $t \mapsto \sigma(t)$, $t \mapsto \rho^{str-ad}(t)$ and $t \mapsto \rho^{wk-ad}(t)$ on $D(\mathcal{H}_S)$ viewed as a ball (the spherical boundary is $D^0(\mathcal{H}_S) \simeq \mathbb{CP}^1 \simeq S^2$ the space of pure states, and the center is $D^\infty(\mathcal{H}_S) = \{ \begin{pmatrix} 1/2 & 0 \\ 0 & 1/2 \end{pmatrix} \}$ the point of the microcanonical state). Each trajectory starts from the south pole, $t \mapsto \sigma(t)$, $t \mapsto \rho^{str-ad}(t)$ and $t \mapsto \rho^{wk-ad}(t)$ are closed whereas $t \mapsto \rho(t)$ ends in the north pole. Right: same as the left figure but with a representation of $D(\mathcal{H}_S)$ in accordance with its fibred structure, the height line of the cone is $\Sigma(\mathcal{H}_S) \simeq [0, \frac{1}{2}]$, the apex is the point of the microcanonical state $D^\infty(\mathcal{H}_S)$, the base is the space of pure states $D^0(\mathcal{H}_S) \simeq \mathbb{CP}^1 \simeq S^2$ (represented as a disk by azimuthal projection) and each circular sections are a fiber $\pi_D^{-1}(p) \simeq \mathbb{CP}^1 \simeq S^2$. $\pi_D : D(\mathcal{H}_S) \to \Sigma(\mathcal{H}_S)$ is then the orthogonal projection onto the height line of the cone.

- the section $\sqrt{\rho^{str-ad}} \in \Gamma(D(\mathcal{H}_S), \mathcal{B}(\mathcal{H}_S))$ associated with the strong adiabatic approximation, i.e. $\rho^{str-ad} = \text{tr}_{\mathcal{H}_A} \Phi_{11} \rangle \langle \Phi_{11}$ with $\Phi_{11}$ defined by eq. (154) applied on the present system. We remark that $\frac{\Phi_{11}}{\text{tr} \rho^{str-ad}}$ is a pure state.

- the section $\sqrt{\rho^{wk-ad}} \in \Gamma(D(\mathcal{H}_S), \mathcal{B}(\mathcal{H}_S))$ associated with a weak adiabatic approximation where $\rho^{wk-ad}(t) = p_1(t) \text{tr}_{\mathcal{H}_A} \Phi_{11} \langle \Phi_{11} \rangle + p_2(t) \text{tr}_{\mathcal{H}_A} \Phi_{21} \rangle \langle \Phi_{21}$.

The sections are represented figure 6 and 7.

We cannot use $\rho^{str-ad}$ since it is a pure state which does not belong to the same stratum that $\rho$ (the strong adiabatic approximation is not satisfied for this dynamics). In the two other cases we have

$$\Psi(t) = \Psi(g_{\eta}(t)g_{\alpha}(t)W(t)k(t))$$

with $k(t) \in K$ the right geometric phase, $g_{\alpha}(t) = \text{Te}^{-\int_0^t i_{W(t')}^{\alpha}(\tau')d\tau'} \in G$ the left geometric phase and $g_{\eta}(t) = \text{Te}^{-i\int_0^t E(\rho(t'))d\tau'}$ the dynamical phase. The geometric phases are drawn figures 8 and 9. The effects of the geometric phases are represented figure 10.
IV. GEOMETRY OF MIXED STATES

A. The geometry as a stratified principal composite bibundle

1. Regular strata

Let $\Sigma'(\mathcal{H}_S)$ be a regular stratum, $\mathcal{D}^i(\mathcal{H}_S) = \pi^{-1}_D(\Sigma'(\mathcal{H}_S))$ be the stratum of the density operators over $\Sigma'(\mathcal{H}_S)$, and $\mathcal{B}^i(\mathcal{H}_S) = \pi^{-1}_S(\mathcal{H}_S)$ be the stratum of the standard purified states over $\mathcal{D}^i(\mathcal{H}_S)$. Let $L_{HS} : G \to \text{Aut}\mathcal{B}^i(\mathcal{H}_S)$ be the left action of $G$ on $\mathcal{B}^i(\mathcal{H}_S)$ defined by

$$\forall g \in G, \forall W \in \mathcal{B}^i(\mathcal{H}_S) \quad L_{HS}(g)W = gW \quad (176)$$

and $R_{HS} : K \to \text{Aut}\mathcal{B}^i(\mathcal{H}_S)$ be the right action of $K$ on $\mathcal{B}^i(\mathcal{H}_S)$ defined by

$$\forall k \in K, \forall W \in \mathcal{B}^i(\mathcal{H}_S) \quad R_{HS}(k)W = Wk \quad (177)$$

These actions of $G$ and $K$ are free. The right action of $K$ can be locally transformed as a left action of $\overline{H}^i$, indeed

$$R_{HS}(k)W = L_{HS}(WkW^{-1})W \quad (178)$$

Because $\pi_{HS}(R_{HS}(k)W) = \pi_{HS}(L_{HS}(WkW^{-1})W) = \pi_{HS}(W) \quad ((WkW^{-1})WW^\dagger(WkW^{-1})^\dagger = WW^\dagger)$, we have $WkW^{-1} \in GL(\mathcal{H}_S)|_{W^\dagger} \subset H^i$.

$\mathcal{B}^i(\mathcal{H}_S)$ cannot be viewed as a left-bundle on $\mathcal{D}^i(\mathcal{H}_S)$ since $\pi_{HS}(gW) = g\pi_{HS}(W)g^\dagger$, but since $\pi_D \circ \pi_{HS}(gW) = \pi_D \circ \pi_{HS}(W)$ we can see $\mathcal{B}^i(\mathcal{H}_S)$ as a left principal $G$-bundle $P^i$ over $\Sigma'(\mathcal{H}_S)$. Let $\phi^i$ be the trivialization of $P^i$:

$$\phi^i : G \times \Sigma'(\mathcal{H}_S) \to \mathcal{B}^i(\mathcal{H}_S)$$

$$\forall (g, \sigma) \in G \times \Sigma'(\mathcal{H}_S) \quad \phi^i(g, \sigma) = g\sqrt{\sigma} \quad (179)$$

FIG. 8. Right geometric phases (top) and left geometric phase (bottom) with respect to the time, for the global section $\sigma(t)$ (left) and the weakly adiabatic dynamics $\rho^{\text{ad}}(t)$ (right). We have use the decomposition of the operators onto $\{\sigma_0, \sigma_x, \sigma_y, \sigma_z\}$ ($\sigma_0 = \mathbb{1}_{\mathbb{C}^2}$) viewed as a basis of $\mathcal{M}_{2 \times 2}(\mathbb{C})$. 

Let $\Sigma'_{HS} : S \to \mathcal{B}^i(\mathcal{H}_S)$ viewed as a basis of $\mathcal{B}^i(\mathcal{H}_S)$ be the stratum of the standard purified states over $\mathcal{D}^i(\mathcal{H}_S)$ and $\mathcal{D}(\Sigma) = 1$. Let $\Sigma(\mathcal{H}_S)$ be a regular stratum, $\mathcal{D}^i(\mathcal{H}_S) = \pi^{-1}_D(\Sigma'(\mathcal{H}_S))$ be the stratum of the density operators over $\Sigma'(\mathcal{H}_S)$, and $\mathcal{B}^i(\mathcal{H}_S) = \pi^{-1}_S(\mathcal{H}_S)$ be the stratum of the standard purified states over $\mathcal{D}^i(\mathcal{H}_S)$. Let $L_{HS} : G \to \text{Aut}\mathcal{B}^i(\mathcal{H}_S)$ be the left action of $G$ on $\mathcal{B}^i(\mathcal{H}_S)$ defined by

$$\forall g \in G, \forall W \in \mathcal{B}^i(\mathcal{H}_S) \quad L_{HS}(g)W = gW \quad (176)$$

and $R_{HS} : K \to \text{Aut}\mathcal{B}^i(\mathcal{H}_S)$ be the right action of $K$ on $\mathcal{B}^i(\mathcal{H}_S)$ defined by

$$\forall k \in K, \forall W \in \mathcal{B}^i(\mathcal{H}_S) \quad R_{HS}(k)W = Wk \quad (177)$$

These actions of $G$ and $K$ are free. The right action of $K$ can be locally transformed as a left action of $\overline{H}^i$, indeed

$$R_{HS}(k)W = L_{HS}(WkW^{-1})W \quad (178)$$

Because $\pi_{HS}(R_{HS}(k)W) = \pi_{HS}(L_{HS}(WkW^{-1})W) = \pi_{HS}(W) \quad ((WkW^{-1})WW^\dagger(WkW^{-1})^\dagger = WW^\dagger)$, we have $WkW^{-1} \in GL(\mathcal{H}_S)|_{W^\dagger} \subset H^i$.

$\mathcal{B}^i(\mathcal{H}_S)$ cannot be viewed as a left-bundle on $\mathcal{D}^i(\mathcal{H}_S)$ since $\pi_{HS}(gW) = g\pi_{HS}(W)g^\dagger$, but since $\pi_D \circ \pi_{HS}(gW) = \pi_D \circ \pi_{HS}(W)$ we can see $\mathcal{B}^i(\mathcal{H}_S)$ as a left principal $G$-bundle $P^i$ over $\Sigma'(\mathcal{H}_S)$. Let $\phi^i$ be the trivialization of $P^i$:

$$\phi^i : G \times \Sigma'(\mathcal{H}_S) \to \mathcal{B}^i(\mathcal{H}_S)$$

$$\forall (g, \sigma) \in G \times \Sigma'(\mathcal{H}_S) \quad \phi^i(g, \sigma) = g\sqrt{\sigma} \quad (179)$$
P is a trivial bundle because of the presence of the global section $\sigma \mapsto \sqrt{\sigma}$. Since $\pi_{HS}(W_k) = \pi_{HS}(W)$, we can see $B^i(\mathcal{H}_S)$ as a right principal $K$-bundle $Q_i$ over $D^i(\mathcal{H}_S)$. Let $\phi^i_Q$ be the trivialization of $Q_i$:

$$\phi^i_Q : D^i(\mathcal{H}_S) \times K \rightarrow B^i(\mathcal{H}_S)$$

(180)

Let $\pi^i_G : G \rightarrow G/H^i$ be the canonical projection ($\pi^i_G(g) = gH^i$). Let $\phi^i_D$ be the trivialization of $D^i(\mathcal{H}_S)$ viewed as a bundle of manifolds:

$$\phi^i_D : G/H^i \times \Sigma^i(\mathcal{H}_S) \rightarrow D^i(\mathcal{H}_S)$$

(181)

$$\pi^i_H \times \text{id}$$

Let $\pi^i_H : H^i \rightarrow G/H^i$ be the projection defined by $\pi^i_H(h) = \pi^i_G(h) (H^i \subset G)$ which is such that $\pi^i_H(gH^i g^{-1}) = gH^i$. The complete geometric structure is then defined by the following commutative diagram:

$$\begin{array}{c}
\overline{H^i} \times \Sigma^i(\mathcal{H}_S) & \overset{\sim}{\rightarrow} & G \times \Sigma^i(\mathcal{H}_S) & \overset{\sim}{\rightarrow} & B^i(\mathcal{H}_S) & \overset{\sim}{\leftarrow} & D^i(\mathcal{H}_S) \times K \\
\pi^i_H \times \text{id} & & \pi^i_G \times \text{id} & & \pi_H & & \text{Pr}_1 \\
G/H^i \times \Sigma^i(\mathcal{H}_S) & \overset{\sim}{\rightarrow} & G/H^i \times \Sigma^i(\mathcal{H}_S) & \overset{\sim}{\rightarrow} & D^i(\mathcal{H}_S) & \overset{\sim}{\rightarrow} & D^i(\mathcal{H}_S) \\
\text{Pr}_2 & & \pi_D & & \Sigma^i(\mathcal{H}_S) & & \Sigma(\mathcal{H}_S)
\end{array}$$

Due to the presence of three floors ($B^i(\mathcal{H}_S)$, $D^i(\mathcal{H}_S)$ and $\Sigma^i(\mathcal{H}_S)$) the bundle of purification is a composite bundle\textsuperscript{34–36}. Due to the both left and right structures, the bundle of purification is a bibundle\textsuperscript{37}. We can then say that $B^i(\mathcal{H}_S)$ is a principal composite bibundle.

FIG. 9. Same as figure but with a space representation of the operators.
The bundle can be rewritten with an arbitrary purification space $H_S \otimes H_A$ with the left and right actions defined by

$$\forall g \in G, \forall \Psi \in H_S \otimes H_A, \quad L(g)\Psi = g \otimes 1_{H_A} \Psi$$

$$\forall k \in K, \forall \Psi \in H_S \otimes H_A, \quad R(k)\Psi = 1_{H_S} \otimes k^i \Psi$$

with $L_{HS}(g)\Psi(W) = \Psi(L(g)W)$ and $R_{HS}(k)\Psi(W) = \Psi(R(k)\Psi(W))$.

2. Singular strata

Let $\Sigma^i(H_S)$ be a singular stratum characterized by $p_1 = 0$ with a degeneracy equal to $n - m$. A density operator $\rho \in \mathcal{D}^i(H_S)$ can be defined by two kinds of data, $P_{\text{Ran} \rho}$ the projection onto its support space and an order $m$ invertible density matrix $\varrho \in \mathcal{M}_{m \times m}(\mathbb{C})$ representing $\rho$ in this space. Let $(\chi_j)_{j=1,\ldots,m}$ be an orthonormal basis of $\text{Ran} \rho$. We have:

$$\rho = \varrho^j_k |\chi_j\rangle\langle \chi_j^k| \quad P_{\text{Ran} \rho} = |\chi_j\rangle\langle \chi_j^j|$$

with $\varrho^j_k = \langle \chi^j | \rho | \chi^k \rangle$. Reciprocally we can introduce $\varphi : \mathcal{D}^i(\mathbb{C}^m) \times V_m(H_S) \rightarrow \mathcal{D}^i(H_S)$ defined by

$$\forall \varrho \in \mathcal{D}^i(\mathbb{C}^m), \forall (\chi_j)_{j=1,\ldots,m} \in V_m(H_S), \quad \varphi(\varrho, (\chi_j)_j) = \varrho^j_k |\chi_j\rangle\langle \chi_j^k|$$

where $\mathcal{D}^i(\mathbb{C}^m)$ is the regular strata for the model Hilbert space $\mathbb{C}^m$ such that $\Sigma^i(\mathbb{C}^m) = \pi_D(\mathcal{D}^i(\mathbb{C}^m))$ is similar to $\Sigma^i(H_S)$ deprived of the zeros. $V_m(H_S) = \{(\chi_j)_{j=1,\ldots,m} \in (H_S)^m, \langle \chi^j | \chi^k \rangle = \delta^j_k \} \simeq V_m(\mathbb{C}^m) = U(m)/U(n-m)(V_m(\mathbb{C}^m)$ is a Stiefel manifold).

Let $I^a \subset \{1,\ldots,n\}$ be a set of indexes such that $\text{dist}_{FS}(P^a, P_{\text{Ran} \rho}) < \frac{\pi}{2}$ where $P^a = \sum_{j \in I^a} |\zeta_j\rangle\langle \zeta_j|$ and $\text{dist}_{FS}(P, Q) = \arccos |\det(Z_P^tZ_Q)|^2$ is the Fubini-Study distance on $G_m(H_S) = \{P \in B(H_S), P^1 = P, P^1 = P, \dim \text{Ran} P = m \} \simeq G_m(\mathbb{C}^m)$ ($Z_P$ is the matrix representing an arbitrary orthonormal basis of Ran$P$ in the basis $(\zeta_j)_j$). There exists a basis $(\chi_j)_j$ of Ran$\rho$ such that

$$\exists c_{jk} \in \mathbb{C}, \quad \chi_j = \zeta_j + \sum_{k \not\in I^a} c_{jk} \zeta_k$$

FIG. 10. Evolution of the occupation probabilities of $\Psi(\tilde{W}(t)k(t))$ (top) and of $\Psi(g_a(t)\tilde{W}(t))$ (bottom) for $\tilde{W}(t) = \sqrt{\sigma(t)}$ (left) and $\tilde{W}(t) = \sqrt{\rho^{k-a}(t)}$ (right).
$U^a = \{ P \in G_m(\mathcal{H}_S), \text{dist}_{FS}(P, P^a) < \frac{1}{2} \}$ is an open chart of $G_m(\mathcal{H}_S)$ with the coordinates map $\xi^a : U^a \to \mathbb{C}^{m(n-m)}$ 
$P \mapsto (c_{jk})_{j \in I^a, k \notin I^a}$.

$V_m(\mathcal{H}_S)$ is a non-trivial principal $U(m)$-bundle over $G_m(\mathcal{H}_S)$ with local trivializations

$$\phi_S^a : U^a \times U(m) \to V_m(\mathcal{H}_S)|_{U^a}$$
$(P, u) \mapsto (Z_P^m u_j^k | \chi^k)$

(187)

with $Z_P^m \in \mathfrak{M}_{mm}(\mathbb{C})$ be such that $(Z_P^m)^j_k = (\langle \chi^j | \chi^k \rangle)_{j \in I^a}$ is an orthonormal basis of $\text{Ran} P$.

Let $H^{10}$ and $H^{11}$ be such that $H^i = H^{10} \times H^{11}$ with $H^{10} \simeq GL(m, \mathbb{C})_\sigma$ ($\sigma \in \Sigma'(\mathbb{C}^m)$) and $H^{11} \simeq GL(n-m, \mathbb{C})$. $G/H^{10} \simeq \hat{V}_m(\mathcal{C}^n) = GL(n, \mathbb{C})/GL(n-m, \mathbb{C}) = V_m(\mathcal{C}^n) \times U(m)$ $GL(m, \mathbb{C}) = \{ ([\chi u^{-1}, u g], u \in U(m), \chi \in V_m(\mathcal{C}^n), g \in GL(m, \mathbb{C}) \}$ is a non-compact Stiefel manifold. Let $\phi_S^a$ be the local trivialization of $G/H^{11}$ induced by $\phi_S^a : U^a \times GL(m, \mathbb{C}) \to \hat{V}_m(\mathcal{C}^n)$
$(P, g) \mapsto ([Z_P^m u^{-1}, u g], u \in U(m))$.

The complete geometric structure is defined by the following commutative diagram:

$$\begin{array}{ccc}
\text{HT} \times \Sigma'(\mathcal{H}_S) & \to & G \times \Sigma'(\mathcal{H}_S) \\
\downarrow_{\phi_S^a \times \text{id}} & & \downarrow_{\text{id} \times \sigma} \\
G/H^{11} \times \Sigma'(\mathcal{H}_S) & \to & \Sigma'(\mathcal{H}_S) \\
\downarrow_{\text{id} \times \pi_G} & & \downarrow_{\pi_D} \\
G/H^{11} \times \Sigma'(\mathcal{H}_S) & \to & \Sigma'(\mathcal{H}_S)
\end{array}$$

where $\pi_G : G \to G/H^{11}$ and $\pi_G^0 : G/H^{11} \to G/(H^{11} \times H^{10})$ are the canonical projections; $\varphi_i (g, P) = \varphi(g, \chi_i i)$ for an arbitrary orthonormal basis $(\chi_i)_i$ of $\text{Ran} P$ and

$$\varphi^* : \mathcal{D}^i(\mathcal{H}_S) \times V_m(\mathcal{H}_S) \to \mathcal{B}^i(\mathcal{H}_S)$$
$(g, \chi) \mapsto \sqrt{g_j} | \chi_i \rangle | \chi^j |$

(188)

$\mathcal{B}^i(\mathcal{H}_S)$ can be viewed as a (non-trivial) right principal $U(m)$-bundle $Q^i$ over $\mathcal{D}^i(\mathcal{H}_S)$ with local trivializations $\varphi^* \circ \phi_S^a \circ \varphi_+^{-1}$. Note that $U(m)$ acts on $\mathcal{B}^i(\mathcal{H}_S)$ by the right action:

$$\forall u \in U(m), \forall W = \varphi^*(g_W, \phi^a(g_W, u_W)) \in \mathcal{B}^i(\mathcal{H}_S), \quad R_{loc}(u)W = \varphi^*(g_W, \phi_S^a(g_W, u_W u))$$

(189)

By construction $\forall u \in U(m), \exists k_{u W} \in K$ such that $R_{loc}(u) = R_{HS}(k_{u W})$. We denote by $K^1_W$ the subgroup of $K$ such that $R_{loc}(U(m))|_{W} = R_{HS}(K^1_W)$. On the left, $\mathcal{B}^i(\mathcal{H}_S)$ is a trivial bundle $P^i$ over $\Sigma'(\mathcal{H}_S)$ with typical fiber $G/H^{11}$ (which is not a group since $H^{11}$ is not normal).

### B. The geometry as categorical principal bundles

We want to endow the geometric structure with a connective structure describing the geometric phases. On the regular strata, the geometric structure is a principal composite bibundle. A connective structure on a principal bibundle and a connective structure on a principal composite bundle present a higher degree of complexity than for an usual principal bundle, the compatibility between the two approaches can be also a difficulty. In order to avoid this, and to unify the geometric description between the left and the right, we propose to use a categorical geometric generalization of the principal bundle.

#### 1. Left principal categorical bundle

We consider a stratum $\Sigma^i(\mathcal{H}_S)$. Let $\mathcal{S}^i$ be the (trivial) category with the set of objects $\text{Obj} \mathcal{S}^i = \Sigma^i(\mathcal{H}_S)$ and the set of morphisms $\text{Morph} \mathcal{S}^i = \{ \text{id}_\sigma, \sigma \in \Sigma^i(\mathcal{H}_S) \}$. Let $\mathcal{P}^i$ be the category with $\text{Obj} \mathcal{P}^i = \mathcal{B}^i(\mathcal{H}_S)$ and $\text{Morph} \mathcal{P}^i =$
We can remark that the arrows could also be defined by an action on the left: Morph \( \mathcal{P}^i \), defined by

\[
\forall (W, k) \in \text{Morph} \mathcal{P}^i, \quad s(W, k) = W
\]

\[
t(W, k) = R_{HS}(k)W = Wk
\]

\[
id_W = (W, 1_{\mathcal{H}_S})
\]

the arrow composition being

\[
\forall W \in \mathcal{B}^i(\mathcal{H}_S), \forall k \in K_W^i, \forall k' \in K_W^i, \quad (Wk, k') \circ (W, k) = (W, kk')
\]

By construction, arrows of different strata are not composable. Let \( \varpi_D \in \text{Funct}(\mathcal{P}^i, \mathcal{P}^i) \) be the full functor defined by

\[
\forall W \in \text{Obj} \mathcal{P}^i, \quad \varpi_D(W) = \pi_D \circ \pi_{HS}(W)
\]

\[
\forall (W, k) \in \text{Morph} \mathcal{P}^i, \quad \varpi_D(W, k) = \text{id}_{\pi_D \circ \pi_{HS}(W)}
\]

Note that \( \varpi_D(t(W, k)) = \varpi_D(Wk) = \pi_D(Wkk^{-1}W^\dagger) = \pi_D(WW^\dagger) = t(\varpi_D(W, k)) \).

We can remark that the arrows could also be defined by an action on the left: Morph \( \mathcal{P}^i \) \( \{ (h, W), W \in \mathcal{B}^i(\mathcal{H}_S), h \in W K_W^i W^\ast \subset H \} \) with \( t(h, W) = L_{HS}(h)W \), since \( \exists k \in K \) such that \( h = WkW^\ast \) and \( L_{HS}(WkW^\ast)W = WkWW^\ast = Wk(1 - P_{\ker W}) = Wk (kP_{\ker W} = 0, \forall k \in K_W^i) \).

Let \( \mathcal{G}^i \) be the groupoid defined by \( \text{Obj} \mathcal{G}^i = G \) and \( \text{Morph} \mathcal{G}^i = G \times H \) with the source, the target and the identity maps defined by

\[
\forall (g, h) \in \text{Morph} \mathcal{G}^i, \quad s(g, h) = g
\]

\[
t(g, h) = gh
\]

\[
\text{id}_g = (g, 1_{\mathcal{H}_S})
\]

the usual arrow composition (called the vertical composition of arrows) being

\[
\forall g \in G, \forall h, h' \in H, \quad (gh, h') \circ (g, h) = (g, hh')
\]

and the law of the semi-direct product of groups (called the horizontal composition of arrows) being

\[
\forall (g, h), (g', h') \in G \times H, \quad (g'g, g^{-1}h'gh)
\]

Let \( \mathcal{L} : \text{Morph} \mathcal{G}^i \rightarrow \text{EndFunct}(\mathcal{P}^i) \) be the left action of \( \mathcal{G}^i \) onto \( \mathcal{P}^i \) defined by

\[
\forall (g, h) \in \text{Morph} \mathcal{G}^i, \forall W \in \text{Obj} \mathcal{P}^i, \quad \mathcal{L}_{g,h}(W) = L_{HS}(g)W
\]

\[
\forall (W, k) \in \text{Morph} \mathcal{P}^i, \quad \mathcal{L}_{g,h}(W, k) = (ghW, k)
\]

or similarly by

\[
\begin{array}{ccc}
Wk & \xrightarrow{\mathcal{L}_{g,h}} & ghWk \\
\downarrow & & \downarrow \\
(W, k) & \xrightarrow{\mathcal{L}_{g,h}} & (ghW, k)
\end{array}
\]

The composition of left actions is covariant with the horizontal composition of the groupoid arrows:

\[
\mathcal{L}_{g', h'} \circ \mathcal{L}_{g, h} = \mathcal{L}_{g'g, g^{-1}h'gh} = \mathcal{L}_{(g', h')(g, h)}
\]
The compatibility between the projection functor $\varpi_D$ and the left action endofunctor $L$ is shown by the following commutative diagram (where $\sigma_W = \pi_D \circ \pi_{HS}(W)$):

\[
\begin{array}{ccc}
W & \xrightarrow{\sigma_W} & W_k \\
\downarrow{(W,k)} & & \downarrow{\text{id}_{\sigma_W}} \\
\sigma_W & & \sigma_W
\end{array}
\]

(205)

$\mathcal{P}^i$ is naturally equivalent to $\mathcal{G}^i \times \mathcal{S}^i$ by the trivialization functors $\phi^i : G \rightarrow \mathcal{Funct}(G^i \times S^i)$ and $\bar{\phi}^i : \mathcal{P} \rightarrow \mathcal{Funct}(\mathcal{P}^i, G^i \times S^i)$ defined by

\[
\begin{array}{ccc}
(g, \sigma) & \xrightarrow{\phi^i} & (g, \sqrt{\sigma}) \\
(g, h, \sigma, \text{id}_\sigma) & \xrightarrow{\bar{\phi}^i} & (g, \sqrt{\sigma}, k)
\end{array}
\]

(206)

with $h = \sqrt{\sigma} \sqrt{k}$ and $\sigma_W = \pi_D \circ \pi_{HS}(W)$. We can note that $\phi^i(g, \sigma) = \phi^i(g, \sigma)$.

Viewed as a left principal categorial bundle, the presence of the both left and right actions takes a natural meaning. The right action of $K$ (inobservable reconfiguration of the ancilla) defines the arrows of the purification category whereas the left action of $G$ (unitary and SLOCC transformations of the system) defines endofunctors of the purification category playing the role of gauge changes.

### 2. Right principal categorical bundle

It is possible to reverse the description, by considering that the right action of $K$ defines endofunctors of gauge changes (in accordance with their inobservable character) and that the left action of $G$ defines the arrows.

Let $\mathcal{M}^i$ be the category defined by Obj.$\mathcal{M}^i = D^i(\mathcal{H}_S)$ and Morph.$\mathcal{M}^i = G \times D^i(\mathcal{H}_S)$, with the source, the target, and the identity maps defined by

\[
\begin{align*}
\forall (g, \rho) \in \text{Morph.}\mathcal{M}^i, & \quad s(g, \rho) = \rho \\
& \quad t(g, \rho) = gpg^\dagger \\
& \quad \text{id}_\rho = (1_{\mathcal{H}_S}, \rho)
\end{align*}
\]

(207-209)

the arrow composition being defined by

\[
\forall \rho \in D^i(\mathcal{H}_S), \forall g, g' \in G, \quad (g', gpg^\dagger) \circ (g, \rho) = (g'g, \rho)
\]

(210)

Let $\mathcal{D}^i$ be the category defined by Obj.$\mathcal{D}^i = B^i(\mathcal{H}_S)$ and Morph.$\mathcal{D}^i = G \times B^i(\mathcal{H}_S)$, with the source, the target and the identity maps defined by

\[
\begin{align*}
\forall (g, W) \in \text{Morph.}\mathcal{D}^i, & \quad s(g, W) = W \\
& \quad t(g, W) = gW \\
& \quad \text{id}_W = (1_{\mathcal{H}_S}, W)
\end{align*}
\]

(211-213)
the arrow composition being defined by
\[ \forall W \in B^i(H_S), \forall g, g' \in G, \quad (g', gW) \circ (g, W) = (g'g, W) \] (214)

Let \( \varpi_{HS} \in \text{Funct}(\mathcal{D}^i, \mathcal{M}) \) be the full functor defined by
\[ \forall W \in \text{Obj}\mathcal{D}^i, \quad \varpi_{HS}(W) = \pi_{HS}(W) = WW^\dagger \] (215)
\[ \forall (g, W) \in \text{Morph}\mathcal{D}^i, \quad \varpi_{HS}(g, W) = (g, WW^\dagger) \] (216)

Let \( \mathcal{X}^i \) be the groupoid with \( \text{Obj}\mathcal{X}^i = K^i \) and \( \text{Morph}\mathcal{X}^i = K^i \ltimes K^i \) (where \( K^i_W \simeq K^i \), \( \forall W \in B^i(H_S) \): \( K^i = K \) on the regular strata), with the source, the target and the identity maps defined by
\[ \forall (q, k) \in \text{Morph}\mathcal{X}^i, \quad s(q, k) = k \] (217)
\[ t(q, k) = qk \] (218)
\[ \text{id}_k = (1_{H_S}, k) \] (219)
the usual arrow composition (called the vertical composition of arrows) being
\[ \forall k \in K^i, \forall q, q' \in K^i, \quad (q', qk) \circ (q, k) = (q'q, k) \] (220)
and the law of the semi-direct product of groups (called the horizontal composition of arrows) being
\[ \forall (q, k), (q', k') \in K^i \ltimes K^i, \quad (q'k'q(k')^{-1}, k') = (q', k') \] (221)
Let \( \mathcal{R} : \text{Morph}\mathcal{X}^i \to \text{EndFunct}(\mathcal{D}^i) \) be the right action of \( \mathcal{X}^i \) onto \( \mathcal{D}^i \) defined by
\[
\begin{align*}
W & \quad \text{W}qk \\
(g, W) \downarrow & \quad \mathcal{R}_{q, k} \downarrow \quad (g, Wqk) \\
gW & \quad \text{gW}qk \\
\end{align*}
\] (222)
where to simplify the notations, for the singular strata, we write \( Wk \) in place of \( R_{loc}(k)W \). The composition of right actions is contravariant with the horizontal composition of the groupoid arrows:
\[ \mathcal{R}_{q, k} \circ \mathcal{R}_{q', k'} = \mathcal{R}_{q', q(k')^{-1}, k'k} = \mathcal{R}_{(q', k')}(q, k) \] (223)

The compatibility between the projection functor \( \varpi_{HS} \) and the right action endofunctor \( \mathcal{R} \) is shown by the following commutative diagram (where \( \rho_W = WW^\dagger \)):

\[
\begin{array}{c}
\text{Wqk} \\
\downarrow \mathcal{R}_{q, k} \\
\text{W} \\
\downarrow (g, W) \\
\text{gW} \\
\downarrow \rho_W \\
\text{gW}g^\dagger \\
\downarrow (g, \rho_W) \\
\text{gW}g^\dagger \\
\end{array}
\]
\[
\begin{array}{c}
\text{rhoW} \\
\downarrow \rho_W \\
\text{rhoWg}^\dagger \\
\end{array}
\]

\( \mathcal{D}^i \) is naturally equivalent to \( \mathcal{M}^i \times \mathcal{X}^i \) by the trivialization functors \( \phi_{\mathcal{D}}^i \in \text{Funct}(\mathcal{M}^i \times \mathcal{X}^i, \mathcal{D}^i) \) and \( \tilde{\theta}_{\mathcal{D}}^i \in \text{Funct}(\mathcal{D}^i, \mathcal{M}^i \times \mathcal{X}^i) \) defined by
\[
\begin{align*}
\begin{array}{c}
\text{(gW}g^\dagger, \sqrt{gW}g^\dagger, \sqrt{gW}g^\dagger) \\
\downarrow \phi_{\mathcal{D}}^i \\
\text{(gW}g^\dagger, \sqrt{gW}g^\dagger, \sqrt{gW}g^\dagger) \\
\end{array}
\end{align*}
\]
\[
\begin{align*}
\begin{array}{c}
\text{(W}g^\dagger, \sqrt{W}g^\dagger, \sqrt{W}g^\dagger) \\
\downarrow \tilde{\theta}_{\mathcal{D}}^i \\
\text{(gW}g^\dagger, \sqrt{gW}g^\dagger, \sqrt{gW}g^\dagger) \\
\end{array}
\end{align*}
\]
\[
\begin{align*}
\begin{array}{c}
\text{W} \\
\end{array}
\end{align*}
\]

|-------------------|-------|--------------------------|--------------------------|----------------------------------|
| left base category | $\mathcal{C}$ | $\Sigma^i(\mathcal{H}_S)$ | $\text{id}_{\Sigma^i(\mathcal{H}_S)}$ | space of the statistical probabilities |
| right base category | $\mathcal{M}$ | $\mathcal{D}^i(\mathcal{H}_S)$ | $G \times \mathcal{D}^i(\mathcal{H}_S)$ | quantum mixed state space with system transformations |
| left total category | $\mathcal{P}$ | $\mathcal{B}^i(\mathcal{H}_S)$ | $\mathcal{B}^i(\mathcal{H}_S) \times \mathcal{B}^i(\mathcal{H}_S)$ | quantum purified state space with ancilla transformations |
| right total category | $\mathcal{Q}$ | $\mathcal{B}^i(\mathcal{H}_S)$ | $G \times \mathcal{B}^i(\mathcal{H}_S)$ | quantum purified state space with system transformations |
| left groupoid      | $\mathcal{G}$ | $K^i$                      | $K^i \ltimes K^i$          | inobservable reconfigurations of the ancilla |
| right groupoid     | $\mathcal{H}$ | $K^i$                      | $K^i \ltimes K^i$          | unitary and SLOCC transformations of the system |

We can note that $\phi^i_{\omega}(\rho, k) = \phi^i_{\Omega}(\rho, k)$. The arrows of the groupoid are $K^i \ltimes K^i$ because $(\sqrt{g\rho}g^{-1}, \sqrt{\rho}, k)$ models the transition from $K^i_{\gamma \theta(k)}$ to $K^i_{\gamma \theta(k)}$ over the arrow $(g, \rho) \in \text{Morph.}\mathcal{M}$.

We remark that we can unify the categories: $\mathcal{P} = \bigsqcup \mathcal{P}^i$ and $\mathcal{Q} = \bigsqcup \mathcal{Q}^i$, on which act the groupoids $\mathcal{G} = \bigsqcup \mathcal{G}^i$ and $\mathcal{H} = \bigsqcup \mathcal{H}^i$ (except that the arrows of different strata cannot be composed neither horizontally nor vertically). $\mathcal{P}$ and $\mathcal{Q}$ can be viewed as kinds of categorical principal bundles, but not strictly as principal 2-bundles $\mathcal{21,22,23,39}$ (the direct categorical generalization of the principal bundles) since in contrast with $\mathcal{G}^i$ and $\mathcal{H}^i$, $\mathcal{G}$ and $\mathcal{H}$ have not the structure of Lie crossed modules $\mathcal{21,22,23,39}$.

Table [IV] summarizes the roles of the different entities in the category formalism, and table [V] summarizes the category structures.

C. Connections

1. The connective structure of the left principal categorical bundle

A connection on a principal 2-bundle with base space being a trivial category is $\mathcal{21,24}$ the data of a family of connections on the objects related by kinds of gauge change associated with the arrows.

More precisely, let $\mathcal{B}^i(\mathcal{H}_S) = \text{Obj } \mathcal{P}^i$ be viewed as a principal bundle over $\Sigma^i(\mathcal{H}_S)$. For $W \in \mathcal{B}^i(\mathcal{H}_S)$, the (left) vertical tangent space at $W$ is defined by

$$V^i_W = \{XW, X \in \mathfrak{g}_{\Sigma^i(\mathcal{H}_S)}\}$$

where $\mathfrak{g}$ is the Lie algebra associated with $G$ and $\mathfrak{h}^{ij}$ is the Lie algebra associated with $H^{ij}$ ($\mathfrak{h}^{ij} = \{0\}$ on the regular strata). We define the (left) horizontal tangent space at $W$ by

$$H^i_W = \{WX, X \in \mathfrak{h}^{ij}, XW^* = 0\}$$

On the regular strata, $H^i_W \mathcal{B}^i(\mathcal{H}_S)$ is a connection for the G-principal bundle $\mathcal{B}^i(\mathcal{H}_S)$. This connection is characterized by the connection 1-form $\omega^i_W \in \Omega^1(\mathcal{B}^i(\mathcal{H}_S), \mathfrak{g})$ defined by $\omega^i_W(X) = WX^{-1}$. On the singular strata, we consider the trivial $G$-bundle $G \times \Sigma^i(\mathcal{H}_S)$ and we set an arbitrary connection $H^i_W(\mathcal{H}_S)$ such that $\phi^i_{\omega}(\eta_W)H^i_W(\mathcal{H}_S)$ on $G \times \Sigma^i(\mathcal{H}_S)$ is the connection 1-form of $G \times \Sigma^i(\mathcal{H}_S)$. Two different choices of arbitrary connections in $H^i_W(\mathcal{H}_S)$ are related by $\omega^i_W - \omega_\nu_W = \eta_W \in \Omega^1(\mathcal{B}^i(\mathcal{H}_S), \mathfrak{h}^{ij})$ which is a $\mathfrak{h}^{ij}$-gauge change of the second kind.
Let $\Phi: \text{Obj}P^i \to G$ be a left equivariant map from $B^i(H_S)$ to $G$ ($\forall W \in B^i(H_S)$, $\forall g \in G$, $\Phi(gW) = g\Phi(W)$). $\Phi$ defines a gauge transformation $a_\Phi: \text{Obj}\mathcal{D}^i \to \text{Obj}\mathcal{D}^i$ by $a_\Phi(W) = \Phi(W)$. Under this gauge transformation, the connection 1-form becomes:

$$a_\Phi^*\omega_W^L(\mathcal{X}) = \omega_{\Phi(W)}^L(a_\Phi^*\mathcal{X})$$

(228)

$$= \omega_{\Phi(W)}^L(\Phi(W)\mathcal{X}) + \omega_{\Phi(W)}^L(d\Phi(W)\Phi(W)^{-1}\Phi(W)W)$$

(229)

since $\forall \gamma(t)$ a curve on $B^i(H_S)$ having $\mathcal{X}$ as tangent vector at $t = 0$ ($\gamma(0) = W$), we have $\frac{d}{dt}a_\Phi(\gamma(t)) = \frac{d}{dt}(\Phi(\gamma(t))\gamma(t)) = \frac{d\Phi(\gamma(t))}{dt}\gamma(t) + \Phi(\gamma(t))\frac{d\gamma(t)}{dt}$, and then $a_\Phi^*\mathcal{X} = \frac{d}{dt}a_\Phi(\gamma(t))|_{t=0} = d\Phi^{-1}\Phi W + \Phi\mathcal{X}$ ($d\Phi^{-1}: B^i(H_S) \to g$). It follows that

$$a_\Phi^*\omega_W^L(\mathcal{X}) = (\Phi(W)\omega_W^L(\mathcal{X}))(W^{-1}) + d\Phi(W)\Phi(W)^{-1}$$

(230)

Let $\Upsilon: \text{Obj}\mathcal{D}^i \to \bigcup_{W \in B^i(H_S)} K_W^i$ be a right equivariant map ($\forall W \in B^i(H_S)$, $\forall k \in K_W^i$, $\Upsilon(Wk) = \Upsilon(W)k$). $\Upsilon$ defines another kind of gauge transformation $a_\Upsilon: \text{Obj}P^i \to \text{Obj}P^i$ by $a_\Upsilon(W) = W\Upsilon(W)$. Under this gauge transformation of the second kind, the connection 1-form becomes

$$a_\Upsilon^*\omega_W^L(\mathcal{X}) = \omega_{W\Upsilon(W)}^L(a_\Upsilon^*\mathcal{X})$$

(231)

$$= \omega_{W\Upsilon(W)}^L(\Upsilon(W)\mathcal{X}) + \omega_{W\Upsilon(W)}^L(W\Upsilon(W)W^{-1}\Upsilon(W))d\Upsilon(W))$$

(232)

since $\frac{d}{dt}a_\Upsilon(\gamma(t)) = \frac{d\Upsilon(t)}{dt}a_\Upsilon(\gamma(t)) + \gamma(t)\frac{d\gamma(t)}{dt}$, and then $a_\Upsilon^*\mathcal{X} = \Upsilon(W)\mathcal{X} + W\Upsilon^{-1}d\Upsilon(\Upsilon^{-1}d\Upsilon; B^i(H_S) \to \mathfrak{k}_W^i; \mathfrak{k}_W^i$ being the Lie algebra of $K_W^i$). It follows that

$$a_\Upsilon^*\omega_W^L(\mathcal{X}) = \omega_{W\Upsilon(W)}^L(\mathcal{X}) + Wd\Upsilon(W)\Upsilon^{-1}W^*$$

(233)

$$(Wd\Upsilon^{-1}W^*)W^* + W\Upsilon^{-1}(Wd\Upsilon^{-1}W^*)^t = Wd\Upsilon^{-1}W^* + W\Upsilon^{-1}W = 0,$$

we have then $Wd\Upsilon(W)\Upsilon^{-1}W^* \in g\mathfrak{L}(H_S)$. If $\omega_{\mathcal{X}}^L = \omega^L - \Upsilon^{-1}W\Upsilon^{-1}W^*$. The gauge transformation of the second kind is then a $\mathfrak{g}^\mathfrak{L}$ gauge transformation. The connection on $\mathcal{D}^i$ is then not constituted by a single usual connection of $B^i(H_S)$, but by a family of usual connections of $B^i(H_S)$ related by additions of $\mathfrak{g}^\mathfrak{L}$-valued 1-forms.

We are now able to provide the local expressions of the connection. Let $s \in \Gamma(\Sigma^i(H_S), B^i(H_S))$ be a local section ($s: \sigma \to W_s(\sigma)$). We have

$$s^*\omega^L = dW_s^*W_s^* = s^A \in \Omega^1(\Sigma^i(H_S), g)$$

(234)

The $G$-gauge potential $s^A$ of the connection is the generator of the operator valued geometric phase (the connection having been defined for that purpose). Under a gauge change of the first kind $W_s(\sigma) \to g(\sigma)W_s(\sigma)$ (with $g \in \Omega^0(\Sigma^i(H_S), G)$), the gauge potential becomes:

$$g^*s^A = g^*s^A g^{-1} + dgg^{-1}$$

(235)

Under a gauge change of the second kind $W_s(\sigma) \to W_s(\sigma)k(\sigma)$ (with $k \in \Omega^1(\Sigma^i(H_S), K_{W_s(\sigma)})$), the gauge potential becomes:

$$k^*s^A = s^A + s^\eta_k$$

(236)

with $s^\eta_k = W_s dkk^{-1}W_s^* \in \Omega^1(\Sigma^i(H_S), \mathfrak{h})$ (the $\mathfrak{g}^\mathfrak{L}$-potential-transformation becomes under a gauge change of the first kind $g^*s^\eta_k = g^*s^\eta_g k^{-1}$). The arbitrary nature of the $\mathfrak{g}^\mathfrak{L}$-potential-transformation is clear in the formalism (it is gauge change of the second kind).

The composite nature of the bundle $B^i(H_S)$ permits also to consider an intermediate entity between the local and the global expression of the connection. Let $s^A \in \Gamma(\mathcal{D}^i(H_S), B^i(H_S))$ be the local section $(s^A(\rho) = W_s^A(\rho))$ such that $s^A(\rho) = \pi_{HS}(s(\pi_{D}(\rho)))$. The 1-form:

$$s^{\bullet^*}\omega^L = dW^*_s W^*_s = s^\mathfrak{h} \in \Omega^1(\mathcal{D}^i(H_S), g)$$

(237)

satisfies for all $h \in \Omega^0(\mathcal{D}^i(H_S), \mathfrak{h})$ such that $h(\rho) \in GL(H_S)_p = g_p H_i \eta_p^{-1} (\phi_i^D(g_p, \pi_D(\rho)) = \rho)$, the following gauge transformation rule:

$$h s^\mathfrak{h} \mathfrak{h} = h s^\mathfrak{h} \mathfrak{h}^{-1} + dh h^{-1}$$

(238)
Property 3 For all $g \in \Omega^0(D^i(\mathcal{H}_S), G)$ we have

$$s^* \mathfrak{A}(gpg^\dagger) = g^* s^* \mathfrak{A}(\rho) g^{-1} + dgg^{-1} + g^* \eta(g, \rho) g^{-1}$$

(239)

where $^* \eta \in \Omega^1(G \times D^i(\mathcal{H}_S), \overline{\mathcal{H}})$ is a gauge change of the second kind.

Proof: For all $g \in D^i(\mathcal{H}_S)$, there exists $k_p \in K$ such that $s^* \mathfrak{H}(\rho) = W^* s^* \mathfrak{H}(\rho) = \sqrt{\rho^*} k_p$. In a first time, we consider the case of the global section $s^* \mathfrak{H}(\rho) = \sqrt{\rho}$.

$$d\sqrt{\rho} \sqrt{\rho} + \sqrt{\rho} d\sqrt{\rho} = dp \Rightarrow d\sqrt{\rho} \sqrt{\rho} + (d\sqrt{\rho} \sqrt{\rho})^\dagger = \frac{1}{2}(dp + dp^\dagger)$$

(240)

$$\Rightarrow \exists X_{\rho}, \text{ s.t. } X_{\rho}^\dagger = -X_{\rho}, \quad d\sqrt{\rho} \sqrt{\rho} = \frac{1}{2}dp + X_{\rho}$$

(241)

$$d\sqrt{\rho} \sqrt{\rho} = \frac{1}{2}dp^* + X_{\rho} \rho^*$$

(242)

We denote by $\sqrt{s^* \mathfrak{H}(\rho)} = d\sqrt{\rho} \sqrt{\rho}$ the gauge potential for the global section, and by $\text{id}^s s^* \mathfrak{H}(\rho) = \frac{1}{2}dp^*$. By noting that $X_{\rho} \rho^* + \rho(X_{\rho} \rho^*)^\dagger = 0$, we see that $\sqrt{s^* \mathfrak{H}}$ and $\text{id}^s s^* \mathfrak{H}$ are related by a $\overline{\mathcal{H}}$-gauge change.

$$\sqrt{s^* \mathfrak{H}(gpg^\dagger)} = \text{id}^s s^* \mathfrak{H}(gpg^\dagger) + X_{gpg^\dagger \rho^\dagger} g^{-1} \rho^* g^{-1}$$

(243)

$$= \frac{1}{2}(d(gpg^\dagger)(gpg^\dagger)^* + X_{gpg^\dagger \rho^\dagger} g^{-1} \rho^* g^{-1})$$

(244)

$$= \frac{1}{2}gdpp^* g^{-1} + dgg^{-1} + g \left( \frac{1}{2} gp^1 g^1 g^{-1} \rho^* - \frac{1}{2} g^{-1} dg + g^{-1} X_{gpg^\dagger \rho^\dagger} g^1 \rho^* \right) g^{-1}$$

(245)

$$= g \sqrt{s^* \mathfrak{H}(\rho)} g^{-1} + dgg^{-1} + g \left( \frac{1}{2} gp^1 g^1 g^{-1} \rho^* - \frac{1}{2} g^{-1} dg + g^{-1} X_{gpg^\dagger \rho^\dagger} g^1 \rho^* - X_{\rho} \rho^* \right) g^{-1}$$

(246)

$\eta_1 \rho + \rho \eta_1^\dagger = 0$, $\eta_1$ is a $\overline{\mathcal{H}}$-gauge change.

We return to the general case:

$$s^* \mathfrak{A}(\rho) = dW^* s^* \mathfrak{H}(\rho) = \sqrt{s^* \mathfrak{H}(\rho)} + \sqrt{dk_p k_p^{-1} \sqrt{\rho}}$$

(247)

$$s^* \mathfrak{A}(gpg^\dagger) = g \sqrt{s^* \mathfrak{H}(\rho)} g^{-1} + dgg^{-1} + g \eta_2(g, \rho) g^{-1} + \sqrt{gpg^\dagger dk_p k_p^{-1} g^1 \sqrt{gpg^\dagger}}$$

(248)

$$= g \sqrt{s^* \mathfrak{H}(\rho)} g^{-1} + dgg^{-1} + g \eta_2(g, \rho) g^{-1} + \sqrt{gpg^\dagger dk_p k_p^{-1} g^1 \sqrt{gpg^\dagger}}$$

(249)

$$\eta_2 \rho + \rho \eta_2^\dagger = g^{-1} \sqrt{gpg^\dagger dk_p k_p^{-1} g^1 \sqrt{gpg^\dagger}} g p - \sqrt{dpk_p k_p^{-1} \sqrt{p} + dp \sqrt{gpg^\dagger k^1 k_p^{-1} \sqrt{gpg^\dagger}}} g^1$$

(250)

Since $dk^{-1} = -dk^{-1}$ and $pg^1 = g^{-1} \sqrt{gpg^\dagger} \sqrt{gpg^\dagger} \Rightarrow pg^1 \sqrt{gpg^\dagger} = g^{-1} \sqrt{gpg^\dagger}$, we have $\eta_2 \rho + \rho \eta_2^\dagger = 0$, $\eta_2$ is a $\overline{\mathcal{H}}$-gauge change.

$s^* \mathfrak{A}$ plays the roles of a $\overline{\mathcal{H}}$-gauge potential and of a $G/H^i$-connection 1-form. The local and the intermediate expressions of the connection are related by

$$s^* \mathfrak{A}(\rho) = g_p s^* \mathfrak{A}(\pi_D(\rho)) g_p^{-1} + dg_p g_p^{-1} + g_p \eta_2(g_p, \sigma) g_p^{-1}$$

(251)

Conversely we have

$$s^* \mathfrak{A}(\rho) = (\pi_D^* s^* \mathfrak{A})(\sigma)$$

(252)

$s^* \mathfrak{A}$ defines the curving $s^* \mathfrak{B}$ of $\mathcal{B}^i$ as

$$s^* \mathfrak{B} = d^* s^* \mathfrak{A} - s^* \mathfrak{A} \wedge s^* \mathfrak{A} \in \Omega^2(\Sigma^i(\mathcal{H}_S), \overline{\mathcal{H}})$$

(253)
Property 4 $B^L(\sigma) \in \mathfrak{h}_r$

Proof: Since $\mathfrak{A}WW^\dagger = dWW^\dagger$ we have $d\mathfrak{A}WW^\dagger - \mathfrak{A} \wedge d(WW^\dagger) = -dW \wedge dW^\dagger$. It follows that $d\mathfrak{A}WW^\dagger - \mathfrak{A} \wedge \mathfrak{A}WW^\dagger = -dW \wedge dW^\dagger$. We have then $B^LWW^\dagger = \mathfrak{A} \wedge WW^\dagger + dW \wedge dW^\dagger$ and $WW^\dagger B^L = -\mathfrak{A}WW^\dagger \wedge \mathfrak{A}^\dagger + dW \wedge dW^\dagger$, implying that $B^LWW^\dagger + W^\dagger B^L = 0 \Rightarrow B^L \in \mathfrak{gl}(\mathcal{H}_S)_{W^\dagger} \subset \mathfrak{h}_r$. □

Remark, for a regular stratum, $\mathcal{P}^i$ is flat: $B^L = 0$ ($\mathfrak{A} = dW_s W_s^{-1}$ is pure gauge). Under a gauge change of the first kind, the curving becomes

$$gsB^L = g^sB^Lg^{-1}$$

(254)

and under a gauge change of the second kind, it becomes

$$skB^L = sB^L + d^s\eta_k - s\eta_k \wedge s\eta_k - [s\mathfrak{A}, s\eta_k]$$

(255)

As in ref.\textsuperscript{19,21–23} we can define fake curvatures of $\mathfrak{S}^i$, as being $sF^L = d^sA^L - sA^L \wedge sB^L \in \Omega^2(\Sigma^i(\mathcal{H}_S), \mathfrak{g}_C)$ ($sA^L = \text{tr}(X^i \mathfrak{A})X_i$, $(X_i)$ being generators of $\mathfrak{g}_C$) and $sF^{BL} = d^sA^{BL} - sA^{BL} \wedge sB^L \in \Omega^2(\Sigma^i(\mathcal{H}_S), \mathfrak{h}_r)$ ($sA^{BL}$ is the projection of $B(\mathcal{H}_S)$ onto $\mathfrak{gl}(\mathcal{H}_S)_{p}$. $sF^L$ is the fake curvature of $\mathfrak{S}^i$ with respect to the generator of the dynamics and $sF^{BL}$ is the fake curvature of $\mathfrak{S}^i$ with respect to the Sjöqvist-Andersson connection. For the adiabatic case, interpretations of $B^L$ and $F^L$ can be found in ref.\textsuperscript{22}, the curving is a measure of the "kinematic decoherence" (decoherence induced by variations in $\Sigma^i(\mathcal{H}_S)$ during the dynamics), and the fake curvature is a measure of the non-adiabaticity of the system entangled with the ancilla. To understand these quantities in a non-adiabatic context, let $\Psi \in \Gamma(\Sigma^i(\mathcal{H}_S), \mathcal{H}_S \otimes \mathcal{H}_A)$ be a local section of a singular stratum $i$. We denote by $p = (0, ..., 0, p_1,..., p_m) \in \Sigma(n)$ $(m < n = \dim \mathcal{H}_S, p_i \in [0,1])$ the local coordinates of $\sigma \in \Sigma^i(\mathcal{H}_S)$. By a Schmidt decomposition\textsuperscript{22} we can write that

$$\exists \phi^i(p) \in \mathcal{H}_S, \exists \chi^i(p) \in \mathcal{H}_A, \Psi(p) = \sum_{i=1}^{m} \sqrt{p_i} \phi^i(p) \otimes \chi^i(p)$$

(256)

After some algebras, we can show that the curving associated with this section satisfies

$$\text{tr}_{\mathcal{H}_S}(\rho(p)B^L(p)) = \sum_{i=1}^{m} p_i (F_A(p) - A_S(p) \wedge A_S(p))_{ii}$$

(257)

with $\rho(p) = \pi_A(\Psi(p))$: $F_A(p) = dA_A(p) + A_A(p) \wedge A_A(p) \in \Omega^2(\Sigma^i(\mathcal{H}_S), \mathfrak{M}_{m \times m}(\mathbb{C})$ is the curving associated with the Berry potential of the ancilla vectors of the Schmidt decomposition $A_A(p)_{ij} = \langle \chi^i(p) | p \chi^j(p) \rangle_{\mathcal{H}_A}$. Except non-abelian corrections, the statistical average of the curving $\omega^p(B^L)$ is essentially the average of the ancilla Berry curvature for the Schmidt decomposition. Let $\sigma^a, \sigma^b, \sigma^c \in \Sigma^i(\mathcal{H}_S)$ be three infinitely close points. Let $\langle \sigma^a \sigma^b \sigma^c \rangle$ be the infinitesimal triangular simplex defined by these points. We have

$$e^{-\int_{\langle \sigma^a \sigma^b \sigma^c \rangle} F_A} \simeq Z^{bc} Z^{ca} Z^{ab}$$

(258)

with $(Z^{ab})_{ij} = \langle \chi_i(p^a) | \chi_j(p^b) \rangle$. Now, if $\{ \chi_i(p^a) \}_{i=1,...,m}$ spans the same subspace as $\{ \chi_i(p^a) \}_{i=1,...,m}$, then $Z^{ab}$ is just a matrix of basis change inner to this subspace and $| \det(Z^{ab}) | = 1$. If the subspace spanned by $\{ \chi_i(p^a) \}_{i=1,...,m}$ is different from the subspace spanned by $\{ \chi_i(p^a) \}_{i=1,...,m}$, then $| \det(Z^{ab}) | < 1$. If follows that $\det(e^{-\int_{\langle \sigma^a \sigma^b \sigma^c \rangle} F_A})$ is a measure of the change of subspace in the neighbourhood of the simplex $\langle \sigma^a \sigma^b \sigma^c \rangle$. It follows that $F_A(p)$ measures the propensity of the dynamics to leave the subspace spanned by $\{ \chi_i(p) \}_{i=1,...,m}$. Finally the curving $B^L(p)$ measures the propensity of the dynamics to leave the subspace spanned by $\{ \phi_i(p) \otimes \chi_i(p) \}_{i=1,...,m}$. In order to describe the dynamics in the neighbourhood of $p$ (denoted $\mathcal{V}(p)$), we need a subspace spanned by $\cup_{p' \in \mathcal{V}(p)} \{ \phi_i(p') \otimes \chi_i(p') \}_{i=1,...,m}$. But even if $\mathcal{V}(p)$ is infinitesimal, if $\|B^L(p)\|$ is large, the dimension of this subspace will be larger than $m$. Finally we can understand $B^L(p)$ as the measure of the propensity of the system to leave its initial singular stratum to a less singular stratum. In accordance to this interpretation, $B^L$ is zero in regular strata. With similar arguments $F^L$ and $F^{BL}$ measure the propensity of the system to leave $S_C(\Psi)$ and to leave a regime involving only phases by invariance.
2. The connective structure of the right principal categorical bundle

Let the following commutative diagrams:

\[
\begin{array}{cccc}
\text{Obj} \mathcal{P} & \xrightarrow{\text{id}} & \text{Morph} \mathcal{P} & \\
\downarrow_{\text{HS}} & & \downarrow_{\text{HS}} & \\
\text{Obj} \mathcal{M} & \xrightarrow{s} & \text{Morph} \mathcal{M} & \\
\downarrow_{\text{HS}} & & \downarrow_{\text{HS}} & \\
\end{array}
\]

where we consider \text{Obj} \mathcal{P} as a \(K^1\)-principal bundle on \text{Obj} \mathcal{M} and \text{Morph} \mathcal{P} as \(K^1\times K^1\)-principal bundle on \text{Morph} \mathcal{M}. A connection on a principal 2-bundle with a base space being a non-trivial category is the data of connections \(H_W \text{Obj} \mathcal{P}\) and \(H_{(g,W)} \text{Morph} \mathcal{P}\) compatible in the sense where

\[
\begin{align*}
id_* H_W \text{Obj} \mathcal{P} &= H_{(1_{H_A},W)} \text{Morph} \mathcal{P} \\
t_* H_{(g,W)} \text{Morph} \mathcal{P} &= H_g W \text{Obj} \mathcal{P} \\
s_* H_{(g,W)} \text{Morph} \mathcal{P} &= H_W \text{Obj} \mathcal{P}
\end{align*}
\]

the vertical tangent spaces being defined by \(V_W \text{Obj} \mathcal{P} = V_W^{R}(H_S) = \{W.X, X \in \mathfrak{t}_W^i\}\) and \(V_{(g,W)} \text{Morph} \mathcal{P} = \{(0,W.X), X \in \mathfrak{t}_W^i\}\). The connections are characterized by connection 1-forms, \(\omega^R_A \in \Omega^1(\text{Obj} \mathcal{M}^i, \mathfrak{t}_i)\) and \(\omega^R_i \in \Omega^1(\text{Morph} \mathcal{M}^i, \mathfrak{t}_i \ni \mathfrak{t}_i)\) related by

\[
\begin{align*}
id^* \omega^R_A &= \omega^R_A \\
s^* \omega^R_A &= \pi^i(\omega^R_A) \\
t^* \omega^R_A &= t^*_{Liec} (\omega^R_A)
\end{align*}
\]

with \(\pi^i: \mathfrak{t}_i \ni \mathfrak{t}_i \rightarrow \mathfrak{t}_i\) and \(t^*_{Liec}: \mathfrak{t}_i \ni \mathfrak{t}_i \rightarrow \mathfrak{t}_i\). Let \(\zeta_o \in \Gamma(\text{Obj} \mathcal{M}^i, \text{Obj} \mathcal{P}^i)\) and \(\zeta_\rightarrow \in \Gamma(\text{Morph} \mathcal{M}^i, \text{Morph} \mathcal{P}^i)\) be the trivializing local sections:

\[
\begin{align*}
zeta_o(\rho) &= \phi^i_o(\rho, 1_{H_S}) = \sqrt{\rho} \\
zeta_\rightarrow(g, \rho) &= \phi^i_\rightarrow(g, \rho, 1_{H_A}, 1_{H_A}) = \left(\sqrt{g \rho g^\dagger}, \sqrt{\rho}\right)
\end{align*}
\]

These local sections satisfy:

\[
\begin{align*}
\zeta_\rightarrow (\text{id}_* \rho) &= \zeta_\rightarrow (\text{id}_* \rho) = (1_{H_A}, \sqrt{\rho}) \\
\zeta_\rightarrow (s(\rho)) &= \zeta_o(s(\rho)) = \sqrt{\rho} \\
\zeta_\rightarrow (t(\rho)) &= \zeta_o(t(\rho)) = \sqrt{g \rho g^\dagger}
\end{align*}
\]

The local data of the connection, the gauge potentials \(A^R_A = \zeta^*_o \omega^R_A \in \Omega^1(\text{Obj} \mathcal{M}^i, \mathfrak{t}_i)\) and \(A^R_i = \zeta^*_\rightarrow \omega^R_i \in \Omega^1(\text{Morph} \mathcal{M}^i, \mathfrak{t}_i \ni \mathfrak{t}_i)\) are such that

\[
\begin{align*}
id^* A^R_A &= A^R_A \\
\pi^i(A^R_A(\rho)) &= A^R_i(\rho) \\
t^*_{Liec}(A^R_i(\rho)) &= A^R_i(g \rho g^\dagger)
\end{align*}
\]

These conditions imply that \(A^R_A(g, \rho) = A^R_A(\rho) + A^R_i(g, \rho)\) with \(A^R_i(g, \rho) \in \Omega^1(\text{Morph} \mathcal{M}^i, \mathfrak{t}_i)\) such that

\[
\begin{align*}
A^R_A(1_{H_S}, \rho) &= 0 \\
A^R_i(g, \rho) &= A^R(g \rho g^\dagger) - A^R(\rho)
\end{align*}
\]

In order to the horizontal lift of the arrows corresponding to the parallel transport of \(\rho\) induces the geometric phases, we must have

\[
\begin{align*}
\begin{array}{c}
(g_{\alpha, \rho}, 1_{H_A}) \\
\downarrow_{\times (g.k)} \quad \downarrow \quad \downarrow_{g_{\alpha}} \\
(g_{\alpha}, g_{\alpha} \rho g_{\alpha}^\dagger, 1_{H_A}) \quad (g_{\alpha}, g_{\alpha} \rho g_{\alpha}^\dagger, q_k) \quad \frac{1}{\sqrt{g_{\alpha}}} \sqrt{g_{\alpha} \rho g_{\alpha}^\dagger k_R}
\end{array}
\end{align*}
\]
where $g_A = T e^{- \int_0^t i \mathcal{A} \, d\tau}$ is the left geometric phase, $k^R = T e^{- \int_0^t i \mathcal{A}^R \, d\tau}$ is the (right) Uhlmann geometric phase, and $(q, k)$ ∈ $\text{Morph} \mathcal{H}$ is the searched horizontal lift:

$$\begin{align*}
(q, k) &= T e^{- \int_0^t i \mathcal{A}_R \, d\tau} \\
&= (T e^{- \int_0^t i \mathcal{A}_R \, d\tau}, T e^{- \int_0^t i \mathcal{A}_R \, d\tau})
\end{align*}$$

(275)

where $i \sqrt{\rho} \mathcal{A}_R = \left( T e^{- \int_0^t i \mathcal{A}_R \, d\tau} \right)^{-1} i \sqrt{\rho} \mathcal{A}_R T e^{- \int_0^t i \mathcal{A}_R \, d\tau}$ by virtue of the intermediate representation theorem.

We have in the definition of the parallel transport $\sqrt{g_A \rho_{g_A} k^R}$ and not $g_A \sqrt{\rho} k^R$ as for the right connection, because we want that the target of parallel transported arrow correspond to an usual parallel transport in the “target bundle”, i.e. $\omega(g_A \rho g_{g_A}) k^R = \sqrt{g_A \rho g_{g_A} k^R}$.

By considering the definition of $\delta_2$ we find

$$\left( \sqrt{g_A \rho g_{g_A}} T e^{- \int_0^t i \mathcal{A}_R \, d\tau}, T e^{- \int_0^t i \mathcal{A}_R \, d\tau} \right) = (g_A, g_A^{-1} \sqrt{g_A \rho g_{g_A} k^R})$$

(277)

inducing that

$$\begin{align*}
T e^{- \int_0^t i \mathcal{A}_R \, d\tau} = \sqrt{g_A \rho g_{g_A}} g_A \\
T e^{- \int_0^t i \mathcal{A}_R \, d\tau} = k^R
\end{align*}$$

(278)

It follows from the last equality that $A^R_R(g, \rho) = A^R(g \rho g^\dagger) \iff A^R_0(g, \rho) + A^R_0(g \rho g^\dagger) = A^R(g \rho g^\dagger)$. We have clearly $A^R_0(\rho) = A^R(\rho)$, the “object” right connection is the Uhlmann connection. From the first equality, we see that the gauge potential of the “arrow” right connection is such that

$$A^R_0(g, \rho) = d \left( \sqrt{g \rho g^\dagger} \right) \left( \sqrt{g \rho g^\dagger} g \sqrt{\rho} \right)$$

(279)

$$= d \sqrt{g \rho g^\dagger} \sqrt{g \rho g^\dagger} + \sqrt{g \rho g^\dagger} dgg^{-1} \sqrt{g \rho g^\dagger} + \sqrt{g \rho g^\dagger} \sqrt{g \rho g^\dagger} g \sqrt{g \rho g^\dagger} g^{-1} \sqrt{g \rho g^\dagger}$$

(280)

$$= \sqrt{g \rho g^\dagger} \left( \Phi^* (g \rho g^\dagger) + dgg^{-1} g \sqrt{\eta(g, \rho) g^{-1}} \right) \sqrt{g \rho g^\dagger}$$

(281)

$\Phi^* (g \rho g^\dagger) = g \sqrt{\eta(g, \rho) g^{-1}} + dgg^{-1} g \sqrt{\eta(g, \rho) g^{-1}}$ by virtue of property. It follows that

$$A^R_0(g, \rho) = -\sqrt{g \rho g^\dagger} g \sqrt{\eta(g, \rho) g^{-1}} \sqrt{g \rho g^\dagger}$$

(282)

The connections define the curving of $\mathcal{D}$ as

$$B^R = dA^R_0 + A^R_0 \wedge A^R + [A^R_0, A^R_0] \in \Omega^2(\text{Morph} \mathcal{H}, \psi)$$

(283)

and the fake curvature of $\mathcal{D}$ as

$$F^R = dA^R_0 + A^R_0 \wedge A^R_0 + B^R \in \Omega^2(\text{Morph} \mathcal{H}, \psi)$$

(284)

$F^R(\eta_A, \rho)$ is just the curvature of the Uhlmann connection, it is a measure of the holonomy with respect to the Uhlmann’s parallelism (relative phase factor) for infinitesimal loops starting from $\rho$. The Uhlmann’s curvature is related to the quantum Fisher information matrix, and it measures the difficulty to realize an estimation of the mixed state by measurements in the neighbourhood of $\rho$. The curving is just a correction associated with the shift between the two purifications of $g \rho g^\dagger$, i.e. $\sqrt{\rho}$ and $\sqrt{g \rho g^\dagger}$.

We can note that it is possible to choose another “object” right connection as the another Uhlmann like connections. In particular, we can choose the Sjöqvist-Andersson connection by replacing $A^R$ by $A^{BR}$, in this case $k^R$ is the Sjöqvist geometric phase, and the rest of the discussion is totally similar. The fake curvature is then written $F^{BR} = dA^{BR} + A^{BR} \wedge A^{BR} + B^R$. The possibility of changing the “object” right connection follows from the definition of the parallel transport of the arrow $(g_A, g_A^{-1} \sqrt{g_A \rho g_{g_A} k^R})$. If we change the definition of the right geometric phase $k^R$ (by passing, for example, from the Uhlmann to the Sjöqvist geometric phase), the arrows (in Morph $\mathcal{D}$ and Morph $\mathcal{H}$) change in consequence, since $g_A$ is generated by $i \sqrt{\mathcal{A}} + \sqrt{g k^R} k^{-1} \sqrt{\rho}$.

Table VI summarizes the different data of the connective structures.
V. CONCLUSION

The Lindblad equation describes a quantum system $S$ in contact with a very large environment (a reservoir) $R$. From a theoretical point of view, if $\Phi \in H_S \otimes H_R$ is the state of the system plus the reservoir, $\rho = \text{tr}_{H_R} |\Phi\rangle\langle\Phi|$ obeys (under some assumptions\textsuperscript{2}) to the Lindblad equation. But in practice, $\Phi$ is unknown because of the very large number of degrees of freedom of $R$ (the partial trace models the forgetting of the “informations” concerning $R$). The purification process permits to introduce $\Psi \in H_S \otimes H_A$ such that $\rho = \text{tr}_{H_A} |\Psi\rangle\langle\Psi|$, where the ancilla $A$ plays the role of a small effective environment. The price to pay is the nonlinearity of the Schrödinger equation governing $\Psi$. The purified dynamics presented in this paper can permit to study the dynamics of open quantum systems submitted to relaxation processes, with the tools used for pure states. In particular we have shown how the geometric phases appear in this context, unifying some concepts previously introduced by different authors. The geometric structure involved by the purification and the geometric phases, is richer than the case of the pure states, and needs the use of the category theory. We hope that these facts can help to understand dynamics of open quantum systems and enlighten the position of the density matrix theory in the landscape of the geometric and gauge structures in theoretical physics. The role of the category theory in quantum physics is an intriguing question, and it could be interesting to study the relations of the structure presented in this paper with the categorical structures proposed in other quantum problems\textsuperscript{22,24}.
