ABSTRACT
A rapid and simple UPLC-MS/MS method was developed to determine toddalolactone in mouse blood and applied to measure the pharmacokinetics of toddalolactone in mice. Blood samples were first preprocessed by ethyl acetate liquid-liquid extraction. Oxypeucedanin hydrate (internal standard, IS) and toddalolactone were gradient eluted from a UPLC BEH C18 column using a mobile phase consisting of acetonitrile and water (0.1% formic acid). Using electrospray ionization (ESI) as the ionization source, multiple reaction monitoring was used to detect the precursor and product ions of m/z 309.2 and 205.2, respectively, for toddalolactone and of m/z 305.1 and 203.0 for IS, respectively, for quantitative detection. A calibration curve was run over the concentration range of 5–4,000 ng/mL (r > 0.995). The matrix effects ranged from 93.5 to 98.4%, and the recovery was higher than 77.3%. The precision was less than 13%, and the accuracy ranged from 90.9 to 108.4%. The developed UPLC-MS/MS method was successfully used for measuring the pharmacokinetics of toddalolactone in mice after oral (20 mg/kg) and intravenous administration (5 mg/kg), and the absolute bioavailability of toddalolactone was 22.4%.

KEYWORDS
toddalolactone, mice, UPLC-MS/MS, determination, bioavailability

INTRODUCTION
The flowering plant species *Toddalia asiatica* (L.) Lam. has been found to be efficacious in treating hemostasis, removing blood stasis, and relieving pain [1]. As a traditional medicine that is used in the Guizhou, Guangxi, and Yunnan provinces, the plant is widely applied in the treatment of rheumatic arthralgia, stroke injury, and swelling. Toddalolactone, a natural coumarin that is produced by *Toddalia asiatica* (L.) Lam, has been shown to exhibit anti-fibrotic and anti-thrombotic effects *in vitro* and *in vivo* [2]. Despite its employment to treat a broad range of conditions, little is known about the absorption, distribution, metabolism, and excretion (ADME) properties of toddalolactone. There have been several literatures reported for determination of toddalolactone in *Toddalia asiatica* (L.) Lam. by HPLC or UPLC-QTOF-MS/MS [3–5]. However, until now, there have been no reports on the pharmacokinetic profile of toddalolactone in biological fluids.

Compared to conventional HPLC, UPLC has better separation ability, better chromatographic peak shape, and less interference from matrix effects [6, 7]. To better understand the pharmacokinetics, an analytical method for the determination of toddalolactone in biological fluids is necessary. Therefore, it was necessary to first develop a UPLC-MS/MS method for
identification of toddalolactone in mouse blood and apply these methods toward the determination of toddalolactone pharmacokinetics.

EXPERIMENTAL

Materials
Toddalolactone and oxypeucedanin hydrate (IS) (both purity >98%) were obtained from Chengdu Munster biotechnology Co. Ltd (Chengdu, China). HPLC-grade formic acid, acetonitrile, and methanol were obtained from Merck, KGaA (Darmstadt, Germany). Milli-Q water system was purchased from Millipore Sigma (Burlington, MA, USA). Twelve Institute of Cancer Research (ICR) mice (male, 20–22 g) were obtained from Laboratory Animal Center of Wenzhou Medical University (Wenzhou, China).

Instrument and condition
An ACQUITY H-Class UPLC equipped with a XEVO TQS-micro triple quadrupole mass spectrometer (Waters Corp, Milford, MA, USA) with electrospray ionization (ESI) was used for the analysis of the mouse blood samples. A UPLC BEH C18 (1.7 μm, 2.1 × 50 mm) column maintained at 30 °C was used for separation. The mobile phase consisted of acetonitrile and water (w/0.1% formic acid). The flow rate was set at 0.4 mL/min. The gradient conditions were as follows: 0–0.2 min, 10% acetonitrile; 0.2–1.4 min, 10–85% acetonitrile; 1.4–2.0 min, 85% acetonitrile; 2.0–2.1 min, 85–10%, acetonitrile; 2.1–3.5 min, 10% acetonitrile.

The mass condition was set as follows: dry gas (nitrogen) flow rate of 900 L/h, capillary voltage of 2 kV, the temperature of source ionization of 150 °C, the temperature for drying gas of 450 °C. Quantitative analysis of the blood samples was operated in ESI positive mode with multiple reaction monitoring (MRM), m/z 309.2 → 205.2 for toddalolactone (cone voltage 20 v, collision voltage 24 v) and m/z 305.1 → 203.0 for IS (cone voltage 34 v, collision voltage 10 v), Fig. 1.

Calibration standards
Stored solutions of toddalolactone (1.0 mg/mL) and oxypeucedanin hydrate (1.0 mg/mL) were prepared in a 1:1 (v/v) solution of methanol and water. Working standard solutions were diluted from the stock solution of toddalolactone with methanol to final concentrations of 50, 200, 500, 1,000, 2,000, and 4,000 ng/mL. The stored stock solution of oxypeucedanin hydrate was diluted with methanol to obtain a working standard solution with a final concentration of 100 ng/mL.

Blank mouse blood was spiked with toddalolactone to generate calibration standards with toddalolactone concentrations of 5, 20, 50, 200, 500, 1,000, 2,000, and 4,000 ng/mL. Three quality control (QC) samples, with concentrations of 10, 450, and 3,600 ng/mL, were also prepared in the same manner as the calibration standards. All samples were stored at −20 °C.

Fig. 1. Chemical structure and mass spectra of toddalolactone (A) and oxypeucedanin hydrate (IS, B)
Sample preparation
The blood sample (20 μL) was added to a 1.5 mL centrifugation tube, and 10 μL of the internal standard solution (100 ng/mL) was added, followed by 1 mL of ethyl acetate. The tube containing the sample was vortexed for 1.0 min and then centrifuged at 3,000 rpm for 10 min at 4 °C; the supernatant (0.9 mL) was then dried under a stream of air and reconstituted in 50 μL of methanol. After centrifugation, the supernatant (2 μL) was injected into the UPLC-MS/MS for analysis.

Method validation
The UPLC-MS/MS method validation was performed according to the US Food and Drug Administration (FDA) bioanalytical guidelines [8].

Selectivity. The selectivity of the UPLC-MS/MS method was evaluated by analyzing blank mice blood, the blank mouse blood spiked with toddalolactone and the IS, and a mouse sample.

Calibration of the Standards. A calibration curve was generated using the standards over the concentration range of 5–4,000 ng/mL. Each peak was integrated to determine the peak area, and the peak areas were plotted against the known standard of the standards to generate a standard curve that was evaluated for its linearity. The lower limit of quantification (LLOQ) was defined as the lowest concentration on the calibration curves. The precision at LLOQ should be less than 20%, and accuracy should be between 80 and 120%. The limit of detection (LOD), defined as a signal/noise ratio of 3.

Precision and accuracy. The precision and accuracy were evaluated by measuring mouse blood QC samples at six replicates. Expressed as relative standard deviation (RSD), the precision on the same day (intra-day) and on different days (inter-day) was determined by measuring the QC samples for three consecutive days. The accuracies of these QC samples on the same day and on different days were measured based on the average value of the QC samples and the true value for three consecutive days.

Recovery and matrix effects. The recovery was evaluated by comparing the measured peak area of the QC samples with the corresponding standard peak area. The matrix effect was evaluated by comparing the peak area of the blank mouse blood with the standard solution after sample treatment and the peak area of the corresponding standard solution.

Stability. The stability of toddalolactone in mouse blood was investigated by analyzing the QC samples placed under three different storage conditions: −20 °C for 30 days (long-term stability), 2 h at room temperature (short-term stability), and 3 consecutive freeze-thawing cycles (−20 °C to room temperature) for 3 days (freeze-thaw stability).

Pharmacokinetics
Twelve mice were randomly divided into two groups (n = 6). One group was given toddalolactone (20 mg/kg) by oral administration and another group was given toddalolactone (5 mg/kg) by intravenous administration. This study was approved by the Animal Care Committee of Wenzhou Medical University. The blood samples (20 μL) were withdrawn from the caudal vein after dosing at 0.167, 0.5, 1, 1.5, 2, 3, 4, 6, 8 h and stored at −20 °C until analysis. The data obtained from UPLC-MS/MS fits the DSA 2.0 (China Pharmaceutical University, China). The bioavailability was calculated using the following equation: bioavailability (%) = 100% × AUCpo / Dpo/(AUCiv × Dpo), where po refers to oral administration, iv refers to intravenous administration.

RESULTS
Method validation
The UPLC-MS/MS chromatograms of a blank blood sample, a blank blood sample spiked with toddalolactone and IS, and a blood sample obtained after oral administration are provided in Fig. 2. No interference was found at the retention times of the toddalolactone and the IS. The calibration curve for the standards that were created over the concentration range of 5–4,000 ng/mL yielded the linear regression equation y = 0.000355 x + 0.000306 (r = 0.9992, n = 6), where y represents the ratio of the peak area of toddalolactone to that of IS, and x is the concentration of toddalolactone. The LLOQ was 5 ng/mL. The precision and accuracy of the LLOQ were 12.5 and 90.9%, respectively. The LOD of toddalolactone in mouse blood was 2 ng/mL. The accuracy of the QC samples ranged from 90.9 to 108.4%, the intra-day and inter-day precision was less than 13%, and the matrix effect was between 93.5 and 98.4%, in Table 1. The stability of toddalolactone in the various conditions (room temperature for 2 h, −20 °C for 30 days, and 3 freezing and thawing cycles) was acceptable, with the accuracy being between 86 and 115% and precision being less than 13%.

Pharmacokinetic study
The main pharmacokinetic parameters of toddalolactone were fitted by the non-compartment model (Table 2). The mean plasma concentration-time profile of toddalolactone after oral administration (20 mg/kg) and intravenous administration (5 mg/kg) is shown in Fig. 3. The bioavailability of toddalolactone was 22.4%, which represents a good oral absorption.

DISCUSSION
To better understand the pharmacokinetics of toddalolactone, mass spectrometry conditions were optimized. The
positive-ion mode provided a stronger response for the detection of toddalolactone than the negative-ion mode. Fragment peaks with relatively high signal intensity were selected as quantitative ion pairs, with $m/z$ 309.2 → 205.2 for toddalolactone (cone voltage 20 v, collision voltage 24 v) and $m/z$ 305.1 → 203.0 for IS (cone voltage 34 v, collision voltage 10 v), were shown in Fig. 1.

Various mobile phases were tested, such as acetonitrile and 0.1% formic acid in water, acetonitrile and water, acetonitrile with 10 mmol/L ammonium acetate, methanol with 0.1% formic acid in water, methanol and water, and methanol with 10 mmol/L ammonium acetate. Based on the elution profiles in each of these mobile phases, acetonitrile

| $V_{z/F}$              | L/kg             | 7.8 ± 2.2     | 1.7 ± 0.2    |
| Bioavailability        | ng/mL            | 2595.5 ± 499.9| 2892.8 ± 544.0|

Various mobile phases were tested, such as acetonitrile and 0.1% formic acid in water, acetonitrile and water, acetonitrile with 10 mmol/L ammonium acetate, methanol with 0.1% formic acid in water, methanol and water, and methanol with 10 mmol/L ammonium acetate. Based on the elution profiles in each of these mobile phases, acetonitrile
with 0.1% formic acid in water was determined to be the best mobile phase because it achieved a better peak with suitable retention time. A UPLC BEH C18 column (Waters) was chosen for chromatography because it provided a better peak shape than other columns tested.

Choosing suitable sample treatment method was an important step in the methodology [9–12]. The extraction efficiencies of acetonitrile, ethyl acetate, and methanol were compared. The extraction efficiencies of ethyl acetate and acetonitrile (around 80%) were similar, which were better than methanol (around 70%). However, the blood sample extraction by acetonitrile had poor matrix effects (around 75%), and the matrix effect from ethyl acetate was better (around 95%). Taking ethyl acetate as the extraction solvent into consideration, the method validation showed that using ethyl acetate for liquid-liquid extraction could obtain satisfactory sensitivity and extraction efficiency. Compared to a rat, the blood volume of a mouse is relatively unsuitable for withdrawing a significant amount of blood, but this experiment only requires 20 μL of blood for pharmacokinetics analysis. However, the small volume of blood withdrawn is not adequate enough for centrifugation to separate the blood for serum analysis. In this study, the accuracy, precision, matrix effect, and stability of the direct liquid-liquid extraction of blood met the requirements of biological testing, which allowed direct use of the blood samples for detection and analysis.

It was also an important task to select the best internal standard during the method development [13–17]. In this experiment, several compounds including diazepam, carbamazepine, oxypeucedanin hydrate, bupivacaine, and lidocaine were compared. Of all the internal standards tested, oxypeucedanin hydrate demonstrated the best peak shape, has a more stable chemical structure, and the peak time was similar to that of toddalolactone, all of which were necessary for correct function of the internal standard in the experiments.

UPLC-MS/MS was utilized in the quantitative analysis of toddalolactone in mouse blood because it was much faster than traditional HPLC. Toddalolactone was eliminated from blood with a t1/2 of 1.3 ± 1.0 and 0.8 ± 0.6 h for intravenous and oral administration, respectively. These results indicated that blood plasma metabolism was fast in mice. The AUC(0–t) of were 3041.6 ± 327.0 and 2725.6 ± 754.3 ng/mL*h for intravenous and oral administration, respectively, which indicated a good oral absorption. The pharmacokinetics of toddalolactone in vivo could help better understand the metabolism of the drug in the body.

CONCLUSIONS

A simple UPLC-MS/MS method was developed for determination of toddalolactone in mice, with an LLOQ of 5 ng/mL and a sample running time of only 3.5 min. The method established in this study only required 20 μL of blood, which is ideal for biological samples with a limited amount of sample available for testing. In addition, the ethyl acetate liquid-liquid extraction, matrix effect, and recovery all met the requirements. The UPLC-MS/MS method developed was then successfully applied to determine the pharmacokinetics of toddalolactone in mice, which had a bioavailability of 22.4%. Toddalolactone was eliminated from blood with a t1/2 of 1.3 ± 1.0 and 0.8 ± 0.6 h for intravenous and oral administration, respectively. The pharmacokinetics of toddalolactone in vivo was reported for the first time, it help better understand the metabolism of the toddalolactone in vivo.
